WINTER-FLOWERING CARNATIONS.

"WINTER-FLOWERING," or, more correctly perhaps, "perpetual flowering" Carnations, are in no sense novelties in British gardens where, for many years past, the best productions of France, Germany, and England have been cultivated. To-day however, the great majority of the varieties that have emanated from the above-named sources appeal to us rather as incidents in the past history of a flower that now impresses the beholder by its beauty, its boldness, and its increasing utility. Most of the modern varieties have been raised in America, a small minority being productions of well-known growers in the British Isles. A representative set of good American varieties are exemplified in such as Enchantress, Robert Craig, Mrs. T. W. Lawson, and White Perfection. Well-grown specimens of these dominate any exhibit of these Carnations, catching and holding the attention. Such a collection affords an excellent proof of what may be accomplished in a few years from small beginnings. Who, for example, a decade and a half ago when the well-known American variety Wm. Scott made its appearance in this country would have dreamed of what was to follow in a few years? Crude in colour, and, from the English florists' standard, rough and worthless, many people said they had thrown better Carnations to the rubbish heap. In Covent Garden market it was openly despised. It so happened, however, that this variety appeared at an opportune moment, just when that universally popular kind, Miss Joliffe, was failing everywhere in its thousands and tens of thousands, filling with consternation the minds of those growers who for years previously had made a leading feature of this variety. With plants of Miss Joliffe dying in this manner the unpleasant prospect of empty glasshouses presented itself, and Wm. Scott, which had reached England and was reputed to be of good constitution, was installed in its place till, as many observed, "something better should turn up." The florist or decorator was not long before he discovered that if flowers of Wm. Scott were magenta coloured when seen in daylight this became toned to a warm rosy pink shade under artificial light, remaining, however, much brighter and more showy than any other variety of Carnation existing at that time. Free and profuse in flowering, and of good constitution, the variety held its own until "Mrs. T. W. Lawson" was introduced to this country, and to this variety rather than its forerunners is due the great popularity of the American Carnation as we know it to-day. Disappointing as first seen by reason of its indifferent form and colour, the variety has since been regarded more favourably, and at the present time and for some years past has been grown in vast quantities for the production of blooms for cutting. Curiously enough, this variety gained an "Award of Merit" from the Royal Horticultural Society when first shown by an almost unanimous vote, but the equally beautiful variety Enchantress did not succeed on its first appearing before that body.

It was "Mrs. T. W. Lawson" that caused the change in the cultivation of Carnations which resulted in the adoption of the method of allowing one flower only to develop on each stem. The change was radical and its importance great, and the Carnation rapidly became one of the most important and highly favoured of all winter flowers. It was during one of his visits to this country that Mr. A. Herrington, of Madison, New Jersey, said to the writer, looking at some poor examples of the flowers of these Carnations at one of the meetings of the R.H.S.: "The more I see of the American Carnation in England, the more I see it requires America's sun." To-day, however, the flowers usually seen greatly surpass those referred to, both in size and colour. At the same time, they suffer materially from the effects of fog and equally so from the dark and sunless days. How much damage a few hours' fog may cause can hardly be estimated, and to a large extent it will depend upon the quality of the fog, its duration, and not least upon the state of the flower buds at the moment. It is during the nascent period of the petals that the Carnation suffers most severely. How penetrating the influences of fog really are may be gathered from the fact that it is the young petals, but carefully enclosed within the calyx, that suffer most of all, and for weeks afterwards the effects of a bad fog may be seen in the opening flowers. In America, bright sunlight and sunheat stimulates the plant day by day, and healthy examples develop their flowers readily. In England, Carnations suffer from absence of sunlight, quite apart from the losses entailed by fogs. From the grower's point of view, the chief remedy—when we remember that it is the backward buds that suffer most—is to so time his crops by stopping and other means that the flower buds will be fully formed before the arrival of the shorter days and the worst period of fogs. In this way his losses may be lessened to some extent.

In the vicinity of large towns, in low-lying districts adjacent to large rivers, and in those areas usually affected by fogs some such method of reducing the losses should be adopted. A problem as yet unsolved is how to keep the fog or the influence of its poisoned vapour from entering the glasshouses, and I am not aware that any practical method has been devised. Practical men might try the effect of heavy, wetted, roller blinds upon the glass, or the still more simple expedient of perforated water pipes attached to either side of the ridge of the house for the purpose of spraying water on to the glass, with a view to hermetically sealing the glass laps against the fog. Should this be found to modify an attack of the fog so far as the roof glass is concerned, there yet remains the ends of the houses, with the doors, &c., to treat successfully. Here, perhaps, some method of glazing could be adopted to render those portions of the building more distinctly airtight.

Generally speaking, the varieties whose flowers have much blue in their composition suffer the most quickly, and of these C. R. Dana, Nelson Fisher, and Wm. Scott are examples. Aristocrat (see fig. 175 in the issue for December 21), a novelty of the moment, is of the same type of colour, and, so far as present experience goes, promises to be a notorious flower in this respect, for it becomes discoloured when exceptionally young. It is an unfortunate failing in an otherwise good and shapely flower. Most of the scarlet-coloured varieties and the crimson-scarlet shades more particularly than the bright scarlet shades, become bleached as the result of fog and the long-continued absence of sunlight. What happens in their case is that the more intense colouring either remains developed, or that this brighter tone is afterwards destroyed, and much slate colour appears instead, giving a dulness and inferiority to the bloom.

All scarlet flowers appear to suffer most when strong chemical manures have been employed in their cultivation. Some of the maroon-crimson shades as The President refuse to develop in winter time, and the crumpled bundle of petals will not unfold. White-flowered kinds and the pink shades suffer the least discoloration, but such full-petalled varieties as Enchantress require a very long time to expand; the well-known variety Fair Maid, with its fewer petals and smaller flowers, being preferred in some instances because it opens so much more freely and quickly.

These facts naturally lead to the question of the improvement to be looked for in the future. So far as England is concerned, the ideal variety for winter-flowering will be that

having comparatively few petals, and in which the petals are of a large uniform size right to the centre. Such a flower in artificial heat will move easily and readily, and the variety whose flowers do this prove most profitable to the grower. Market salesmen and others who do not grow Carnations consider the highest-priced flowers as those best worth growing, openly condemning other kinds. The fact that many of the largest growers still cling to the old types, Wm. Scott for example, may to some extent prove the contrary. It is not always the variety whose flowers realise the highest prices in the market that yields the best returns to the cultivator, but rather the variety that opens quickly and flowers profusely over a long period of time. The grower for market has to consider not what price he gets per bloom, or for a few dozens on the market, but the value of all he can produce from every square yard of glass at home. Whether a variety may prove profitable or otherwise depends not a little upon its perpetual habit of growth and profuse flowering. This idea of perpetual flowering is more interesting to the British than the American grower. Already there are those who begin to doubt if White Perfection will prove profitable. Why? Because at flowering time its stems are practically bare of shoots or growths to continue the flowering, hence a wait of three or four months is necessary before there will be another crop of flowers. Thus it is obvious that a larger number of smaller-sized blooms would be better. Generally speaking, varieties of the "Lawson" type are much in favour for their profuse flowering. Speaking of this as a type, it is interesting to note that while American raisers have given us many of their "pink" varieties, as yet they have not given us a good long-stemmed kind of the exquisite pink tone of the old Miss Joliffe. That most recent pink variety "Winsor" is not only obviously of the Lawson type, but it is a pink with the cerise of Lawson taken out of it. It must, however, at once be said that all of this shade of colour show up splendidly under artificial light, and this, from the decorative point of view, is of the highest importance.

Other qualities to be borne in mind by the raiser of new kinds include that of rigidity of stem, and while some varieties are altogether too weak, others appear to be too rigid and erect. Nonsense! I hear someone say, but I refer entirely to the long-stem flowers, and the longest of these in particular when used full length on a table for example but reveals the back view of a very handsome flower. Moreover, the too rigid stem does not lend itself to the most graceful work, and in the near future the ideal stem will be that which presents the flower to good view by a graceful arch of the upper 8 inches or 10 inches of its stem. The shorter-stemmed "Lawsons," rigid as they are beyond comparison, are valuable by reason of their shortness. On the contrary, where stems are 2½ feet or 3 feet long the rigidity has its drawbacks. In these directions there is abundant room for improvement in the Carnation, and if to these qualities could be added the capacity to withstand the so-called "rust" (Helminthosporium echinulatum), a great work will have been accomplished. *E. H. Jenkins, Hampton Hill.*

LIBERTIA GRANDIFLORA.

THE genus Libertia consists of eight species confined to Australia, New Zealand, and S. America. Most of the species have been in cultivation from time to time, but are still rare in gardens. They are all of very easy culture, thriving best where they can obtain an abundance of moisture at the roots at all times. The subject of the accompanying illustration is the best of the genus for garden purposes, although the nearly-allied L. ixioides is almost as valuable. L. grandiflora is a native of New Zealand, being fairly common throughout both the north and south islands from North Cape to Otago. The elegant and free-flowering habit of the plant, combined with its beautiful pure white flowers, should appeal to all plant lovers. The plant is of good constitution, and does not appear to be at all fastidious as to soil, and it seldom fails to produce an abundant supply of flowers each summer when once it has become established. In very cold districts it is best treated as a greenhouse plant, as it thrives well under pot culture. In common with so many species of New Zealand plants, it is injured by severe frosts, and for this reason, if planted out in the open border, it should be afforded some protection during severe weather. When once established, it is best left alone for a number of years, as it resents any interference with the roots. The inflorescence is an elongated panicle, carried well above the foliage to a height of 2 to 3 feet, and consisting of numerous pedunculed umbels, bearing clusters of five to ten pure white, shortly pedicelate flowers, 1 inch or more in diameter. The fruit, when ripe, is yellow, dividing loculicidally into three valves, and encloses numerous bright, orange-coloured seeds which remain on the plant for several weeks before falling, thus producing a most beautiful effect. The foliage is grass-like in habit, rigid, linear, 1 to 2½ feet long, ½ to ¾ of an inch in diameter, and dark green in colour. *C. P. Raffill.*

FIG. 1.—LIBERTIA GRANDIFLORA AS IT FLOWERED IN THE ROYAL GARDENS, KEW.

NOVELTIES OF 1907.

THE past year has been prolific in the production of good new plants, all branches of floriculture being well reinforced, and especially

THE ORCHIDS.

In this class the home-raised seedlings have taken the greater part of the awards of the Orchid Committee of the Royal Horticultural Society, although there is distinct evidence that pretty species and interesting Orchids of the class denominated "botanical" are steadily increasing in favour; and that albinos, and especially white Cattleyas, still meet with the same appreciation as formerly.

Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), has in 1907 created a record, having secured the Veitchian Cup at the Temple, and on other occasions two Gold Medals, two Silver Medals, and for culture two Silver-Gilt Lindley Medals, and four Cultural Commendations; while his new plants, chiefly raised at Westonbirt, obtained 14 First-Class Certificates and 16 Awards of Merit. The best of these fine novelties were Cattleya Fabia gigantea, C. fulvescens, Westonbirt variety, C. Germania superba, C. Hardyana, Westonbirt variety, all noble flowers of fine colour; C. labiata Purity, the best pure white variety yet flowered; Brasso-Lælio-Cattleya Rowena, Lælio-Cattleya Golden Glory, Miltonia vexillaria, Westonbirt variety, and Cattleya Mossiæ Princess of Wales, three fine plants being exhibited at the Temple Show; Sophro-Lælia-Phroso superba, Sophro-Lælio-Cattleya Phyllis, and S.-L.-C. Medea, all richly-coloured flowers; Lælio-Cattleya Baroness Schroder, Westonbirt variety; L.-C. Ganymede, L.-C. Ortrude, L.-C. Berthe Fournier var. tigrina, Odontoglossum Lady Howick, a very distinct and pretty hybrid; O. crispum Rosemary, a grand form of the white type; Brasso-Cattleya H. G. Alexander (C. citrina × B. Digbyana), a very remarkable cross of distinct features; several good new Cypripediums, Cattleyas, &c.

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), whose collection has developed so remarkably during the last few years, secured First-Class Certificates for the stately and extremely rare Arachnanthe Rohaniana, Cymbidium insigne, Glebelands variety, the handsome Brasso-Cattleya Digbyano-Schroderæ, Fowler's variety; the charming Brasso-Lælio-Cattleya Fowleri, which is unique in colour; and Sophro-Cattleya eximia, Fowler's variety; Awards of Merit for Odontoglossum Aliciæ and the large and finely-shaped Cypripedium Ernest Read; and a Botanical Certificate for the rare Catasetum laminatum. The superbly-blotched Odontoglossum crispum Fowlerianum also flowered in the Glebelands collection, and was illustrated in the *Gardeners' Chronicle*, May 4, p. 278.

Sir TREVOR LAWRENCE, Bart., Burford (gr. Mr. W. H. White), still remains true to the species, both showy and curious, and he adds to his famous collection, which has always been the most interesting and varied in existence, anything that is new and rare. At the same time, good hybrids are not despised at Burford. The species for which Awards were secured during 1907 were the fine Dendrobium regium, which secured a First-Class Certificate; Habenaria Ugandæ, a very remarkable African species; Cirrhopetalum gracillimum, and C. Makoyanum, both graceful species; Hartwegia purpurea, Epidendrum campylostalix, and the large and singular Bulbophyllum longisepalum, for which Mr. White was voted a Cultural Commendation, the specimen having 14 large purple and white flowers, each nearly 6 inches in length.

From the Right Honble. Lord ROTHSCHILD'S gardens, Tring Park, Tring (gr. Mr. A. Dye), the Honble. WALTER ROTHSCHILD also showed some remarkable and rare species, including Lissochilus giganteus, the handsome Stanhopea platyceras, Plocoglottis Lowii, Eulophia ecristata, Bulbophyllum galbinum, Ancistrochilus Rothschildianus, and other new species have flowered at Tring Park, and some of them have been illustrated in the *Gardeners' Chronicle*.

Baron Sir H. SCHRODER, The Dell, Egham (gr. Mr. H. Ballantine), in Odontoglossum John Clarke, which obtained a First-Class Certificate on November 26, showed one of the finest hybrid Odontoglossums of the season.

Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. W. P. Bound), from his splendidly-grown collection, has produced as home-raised novelties the handsome Lælio-Cattleya Epicasta "The Premier," the large-flowered Cœlogyne Colmanii, Spathoglottis Colmanii aurea, Phaio-Calanthe Colmanii and its variety rosea; and the pretty purple-spotted Brasso-Cattleya Mary; and of species the neat little Cirrhopetalum retusiusculum and Acineto Humboldtii Colmanii.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), great in good Cypripediums, and especially in hybrids of C. Lawrenceanum, secured Awards of Merit for C. Mrs. Francis Wellesley (Sanderianum × Gowerianum magnificum), a very beautiful hybrid, and, unlike most other hybrids of C. Sanderianum, a very free grower. Also the ruby-purple C. Tautzianum nigricans, the finely-coloured C. Dicksonianum, and Cattleya Mendelii Francis Wellesley.

J. BRADSHAW, Esq., The Grange, Southgate (gr. Mr. G. G. Whitelegge), received a First-Class Certificate for Cattleya Trianæi The Premier, one of the largest and best of coloured varieties, and Awards of Merit for C. T. Mooreana, with a deep claret-crimson lip; the fine white C. labiata Daphne, and Augusta; and the handsome Odontoglossum venustulum Apollo.

NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman), who recently showed some good results of attempting to improve on the favourite Cypripedium insigne Sanderæ, secured Awards for the fine yellow C. Sanderæ superbum; C. Nandii, Low's variety; and C. Winifred Hollington, Cookson's variety.

Other gentlemen who have received honours for novelties during the year are F. M. OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), for Odontoglossum crispum xanthotes "White Lady" and Sophro-Lælia Gratrixiæ magnifica; F. J. HANBURY, Esq., for the very fine Oncidium leucochilum "Mrs. F. J. Hanbury"; H. S. GOODSON, Esq. (gr. Mr. Day), for Odontoglossum crispum Lily Bourdas, O. ardentissimum "Herbert Goodson," and Cattleya Aliciæ; J. S. MOSS, Esq., Bishop's Waltham, for the handsomely-blotched Odontoglossum crispum Mossii; F. DUCANE GODMAN, Esq., Horsham (gr. Mr. Moody), for Maxillaria grandiflora and Lycaste Ballii, South Lodge variety; C. J. LUCAS, Esq., Warnham Court, Horsham (gr. Mr. Duncan), Lælio-Cattleya Lawrie and Odontoglossum Othello; W. THOMPSON, Esq., Walton Grange (gr. Mr. Stevens), for Odontoglossum Thompsonianum superbum.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), has, during the year, flowered several new and interesting hybrid Odontoglossums, the finest of which, O. Queen Alexandra, var. Carmen, ranks with the best yet produced.

NURSERYMEN.

Messrs. SANDER & SONS, St. Albans and Bruges, have, during the past year, exhibited many new Orchids, obtaining First-Class Certificates for Odontoglossum Prince Edward of Wales, O. crispum xanthotes, White's variety; and O. c. Solum, all good, and the last-named unique in its distinctive characters, and likely to remain so. Awards of Merit were secured for Dendrobium chryseum giganteum, Lælio-Cattleya The Duchess, and the very handsome Cypripedium Fairrieanum "Black Prince." Some of the best of Messrs. SANDERS' other novelties, which have been illustrated in the *Gardeners' Chronicle*, are the finely-blotched Odontoglossum crispum Lord Cromer, O. c. Prince of Asturias, O. Wattianum princeps, O. crispo-Harryanum F. Sander, and Brasso-Cattleya Rajah, a grand hybrid, with flowers of a golden hue delicately tinged and veined with rose-purple.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, showed one of the best new plants of the year in the scarlet Odontioda Bradshawiæ, with which they secured the first First-Class Certificate of the year on January 8. Other awards were obtained for Dendrobium regium, Miltonia Schroderiana, Heaton variety; the extremely rare Angræcum Bryssaii, the richly-coloured Sophro-Cattleya Antiochus, and the very singular Polycycnis Charlesworthii, while of their many other novelties remarked during the year may be mentioned the heavily-blotched Odontoglossum crispum heatonense, one of a small batch of home-raised seedlings; and of the many new hybrids, the pretty O. Phœbe magnificum. Messrs. CHARLESWORTH were also awarded a First-Class Certificate on December 31 for Odontioda Cravenana.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, have for their best the fine Brasso-Catt.-Lælia Veitchii and Cattleya Iris His Majesty, both of which received First-Class Certificates; the remarkable Cypripedium tibeticum, and the floriferous Dendrobium Wilsonii.

Other novelties which have secured awards during 1907 are the fine Odontoglossum ardentissimum Robsoniæ, from Mr. ROBSON, Altrincham; Cymbidium Colmanniæ, Edenside variety, from Mr. JAS. DOUGLAS; Lælia anceps Schroderæ "Grace Ruby" and Odontoglossum Pescatorei ornatum, from Messrs. MCBEAN; and the large and beautiful Cœlogyne asperata, shown by Messrs. MOORE, LTD., Rawdon, Leeds, and which, although known for many years, is still rare. Messrs. MOORE, LTD., also flowered for the first time the pretty Javan Cirrhopetalum biflorum, and some other interesting plants.

CONTINENTAL NOVELTIES.

M. CHARLES VUYLSTEKE, Loochristi, Ghent, has added to his credit some marvellous hybrid Odontoglossums, several of those shown at the Temple Show being unique in colour, the blotchings having a dark violet shade. Three First-Class Certificates were secured on that occasion, viz., for Odontoglossum gandavense, O. eximium "King of England," and O. cœruleum; awards being also obtained for O. caloglossum and O. Ruby.

M. A. A. PEETERS, Brussels, showed the rare Cymbidium Humboldtii at Holland House, and on other occasions the white-petalled Cattleya Warscewiczii Madame Valcke, and the fine Odontoglossum Lambeauianum, var. Idol.

M. GRAIRE secured a First-Class Certificate for his pretty dark-red Odontioda Decrossiana; M. LAMBEAU for Miltonia vexillaria, Lambeau's variety; and Lælio-Cattleya Clive Lambeau's variety.

M. CHAS. MARON showed Brasso-Cattleya Lido; M. JULES HYE DE CROM, the white Miltonia vexillaria Lambeauiana; M. THEODORE PAUWELS, Odontoglossum crispum, Orchid Villa variety; and Messrs. LINDEN, Odontoglossum crispum Roi d'Angleterre, and several other fine, home-raised, blotched varieties of Odontoglossum crispum.

The following new or rare Orchids have been illustrated in the *Gardeners' Chronicle* in 1907:—

Ancistrochilus Rothschildianus, Jan. 26, p. 50.
Ancistrochilus Thompsonianus (for comparison), Jan. 26, p. 51.
Ansellia gigantea, June 8, p. 362.
Brasso-Cattleya Rajah, June 1, p. 351.
Brasso-Lælio-Cattleya Fowleri, May 11, p. 303.
Bulbophyllum galbinum, July 20, p. 42.
Bulbophyllum longisepalum, Sep. 21, p. 211.
Cattleya Warscewiczii (Holford's specimen), supp., Nov. 2.
Cœlogyne Colmanii, Feb. 16, p. 108.
Cypripedium Actæus Langleyense, Jan. 5, p. 12.
Cypripedium californicum, June 29, p. 418.
Cypripedium Morganiæ (specimen), Feb. 2, p. 66.
Cypripediums (Mr. Drewett's), Feb. 16, p. 99.
Dendrobium acuminatum, Sep. 21, p. 210.
Dendrobium fusiforme, May 25, p. 357.
Dendrobium regium, Aug. 17, p. 122.
Grammatophyllum speciosum at Peradeniya, Aug. 31, pp. 169, 170.
Lælio-Cattleya elegans (specimen), supp., Oct. 5.
Lælio-Cattleya Golden Glory, June 1, p. 357.
Neobenthamia gracilis, Aug. 31, p. 174.
Odontioda Bradshawiæ, Jan. 19, p. 36.
Odontoglossum Alexis, Jan. 12, p. 26.
Odontoglossum Beauté Céleste, Jan. 26, p. 56.
Odontoglossum caloglossum, Feb. 2, p. 76.
Odontoglossum crispo-Harryanum F. Sander, March 2, p. 142.
Odontoglossum crispum Fowlerianum, May 4, p. 278.
Odontoglossum crispum heatonense, June 22, p. 409.
Odontoglossum crispum Lord Cromer, June 1, p. 352.
Odontoglossum crispum Prince of Asturias, June 1, p. 353.
Odontoglossum crispum Rosemary, April 6, p. 217.
Odontoglossum John Clarke, Nov. 30, p. 380.
Odontoglossum Prince Edward of Wales, May 11, p. 302.
Odontoglossum Phœbe magnificum, June 1, p. 355.
Odontoglossum Queen Alexandra, var. Carmen, July 7, p. 13.
Odontoglossum Ruby, Feb. 2, p. 76.
Odontoglossum Wattianum princeps, March 2, p. 135.
Pleione yunnanensis, March 9, p. 152.
Sophro-Lælia Phœbe superba, May 4, p. 277.

(To be continued.)

THE ROSARY.

CULTURAL HINTS FOR THE MONTH OF JANUARY.

THE severe weather has rendered it necessary to make provision for covering and soiling up all standard and dwarf plants of tender varieties. I trust the advice given last month as to the advantage of autumn planting has been acted upon, because spring-planting Roses are apt to make top growth first and roots afterwards. Examine the early-planted Roses and Rose cuttings that are likely to become loosened by the shrinking of the soil or by frost, and carefully tread the soil about the roots row by row. This will also include standard and dwarf Briars, Manetti and De la Grifferie stocks and cuttings. Afterwards apply a fresh mulch on the surface of the ground.

The atmospheric temperature of the forcing house may now be raised to 55° during the day time, and when the weather is favourable more air can be given on the south and west sides of the house. An occasional syringing during bright weather, and damping of the ground surfaces in dull weather will be valuable as helping to maintain a humid atmosphere. Close the house early in the afternoon.

A later batch for succession can be brought into the cooler end of the house during the latter part of the month, and the same treatment accorded them as was adopted for earlier ones; following the pruning operation they should be kept for a short period rather drier at the root. Prune the Hybrid Perpetuals to about one-third of their growth, cutting each shoot back to an outward eye. The Tea-scented and Noisette varieties do not require to be pruned so closely, but merely to have the weak and unripened growths removed, shortening very moderately the strong flowering shoots.

The Tea-scented varieties will bear a much warmer atmosphere than the Hybrid Perpetuals It should be distinctly understood that the treatment just described applies only to established plants that were potted-up during the late spring and have been plunged out-of-doors all the summer. Plants that were planted in October can be brought into a cold house or frame. Slightly prune them, and keep the roots moderately dry; this will cause the lower buds to swell. The final pruning can be carried out during February and March. At present the atmospheric temperature need not exceed 45°, but it should not fall below 40°. The house at present can remain closed, but a little air may be given after a month has elapsed on bright days only.

When it is intended to fumigate or vaporise the house, it should be kept perfectly dry, and no moisture should hang about the plants. This operation is best done on a quiet still evening, and if it is found that one fumigation is insufficient to kill the insects, let it be followed by another of medium strength early on the next morning. This will be found more effective and economical than making more severe operations at longer intervals, and there will be less liability of the foliage getting scorched or otherwise injured.

Herbaceous or soft grafting will now be well to the fore. The earliest-forced Roses will now provide plenty of available and sufficiently ripened wood for the purpose, and when new or scarce varieties have to be propagated quickly, it is customary to cut up each bud and leaf of the shoot for a scion; the terminal growth being softer can be used entire. The tops of the early grafts will also now be sufficiently forward to supply material for the same purpose.

A good look-out must be kept for the maggot and grub that infests the leaves and buds of inside Roses, which should be picked off and destroyed.

The grafts on the roots of seedling Briars need to be brought on cautiously at present; a little air for an hour or two to dry up the damp may be given during the morning, and at present only a moderate bottom heat until root-action has commenced and some top growth has been made, when more heat and air can be given them.

The growths of most out-of-door Roses made during last season will be found to be rather soft and imperfectly matured, and I shall not be surprised to see them badly injured if the weather becomes very severe. *J. D. G*

ODONTOGLOSSUM CRISPUM.

OUR illustration (fig. 2) represents a specimen of Odontoglossum crispum cultivated from a single pseudo-bulb by Mr. H. G. Alexander, Orchid grower to Major G. L. Holford, C.V.O., C.I.E., Westonbirt, Tetbury. It illustrates the advantages to be derived from dividing Orchids in the manner often urged in these pages. The plant illustrated having an extraordinary proportion of leading growths, has produced an unusual number of flower-spikes.

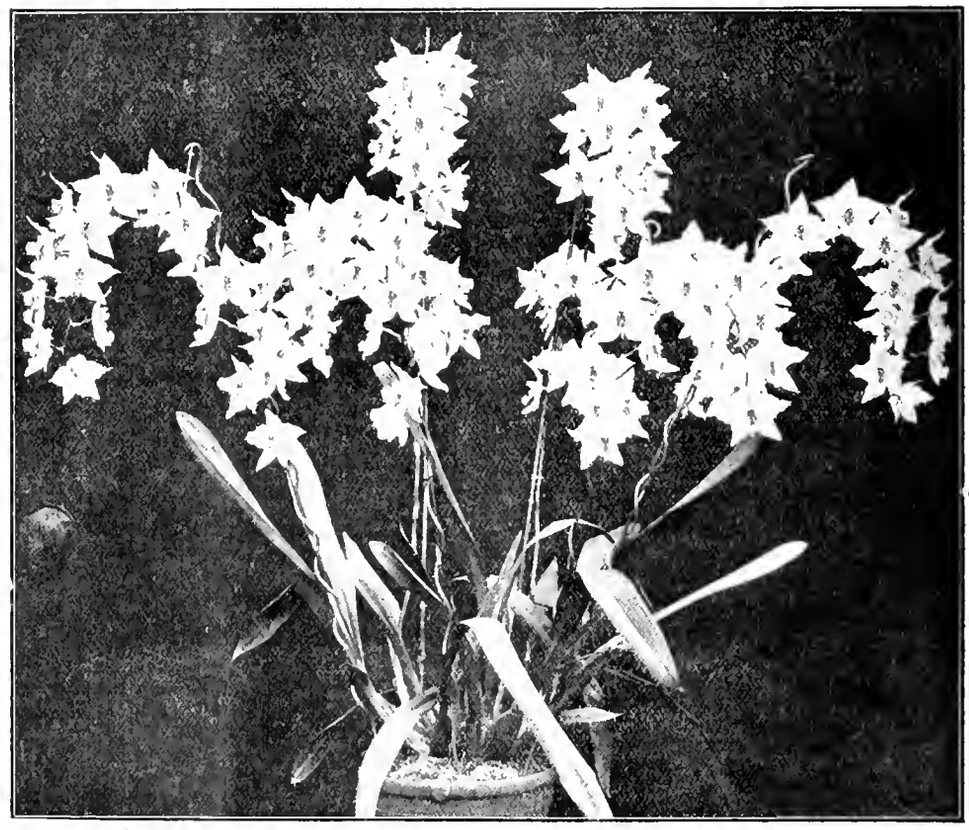

FIG. 2.—A FINELY-FLOWERED PLANT OF ODONTOGLOSSUM CRISPUM FROM MAJOR HOLFORD'S COLLECTION.

LAW NOTE.

THE SMALL HOLDINGS AND ALLOTMENTS ACT 1907.

DURING the passage of the Small Holdings Act through the Houses of Parliament the supporters of the Bill expressed their firm conviction that its provisions would enable many who are now working for others to become proprietors of their own land and employers of labour. It is not difficult to imagine the dismay of those who, in the hope that it might prove of practical benefit to themselves, have endeavoured to follow the scheme of an Act which, in addition to containing 47 clauses and two schedules, either amends or incorporates nearly a dozen other Acts of Parliament, which in their turn refer to other statutes of still earlier date. A short summary of the new Act may therefore help to remove some of the difficulties of those who are thus circumstanced. Putting the matter as shortly as possibly, the Act may be divided into three heads, namely, Part 1, which deals with "Small Holdings," Part 2 which deals with "Allotments," and Part 3 which relates to general matters.

SMALL HOLDINGS.

It may be explained in the first place that a small holding means an agricultural holding which exceeds one acre and either does not exceed 50 acres or, if exceeding 50 acres, is at the date of sale or letting of the value for the purpose of Income-tax of not more than £50 a year.

The Act in the first place provides for the appointment of two or more persons possessed of a knowledge of agriculture who are to be known as the Small Holdings Commissioners. It is the duty of these officials acting under the Board of Agriculture to ascertain the extent to which there is a demand for small holdings, or for which there would be a demand if suitable land were available in various parts of the country, and for this purpose to confer with the County Councils and others. The Board of Agriculture may then communicate with the County Councils, and thereupon it will be the duty of the latter to prepare draft schemes with a view to carrying out the reports of the Commissioners and submit these schemes to the Board for approval or modification by them. If the County Council declines to undertake this duty, or if it fails to prepare such schemes within six months after receiving the report from the Board, then the Small Holdings Commissioners may proceed to prepare draft schemes.

The County Council may, however, submit a draft scheme without waiting to be approached by the Commissioners, and in this event the draft scheme may specify: (a) the localities in which land is to be acquired for small holdings; (b) the approximate quantity of land to be acquired, together with other details; (c) whether and if so to what extent grazing or other similar rights should be attached to the holdings; and (d) the time in which the scheme is to be carried into effect. Subsequently a draft scheme is to be published and advertised so as to enable objections to be sent in to the Board, and, if necessary, the Board can hold a public local enquiry on the subject.

A person who desires to avail himself of the machinery thus provided to enable him to obtain a small holding can either purchase the holding outright or take it on lease. The Council in its

turn can either buy the land compulsorily from the existing holder, or can take it on lease from him and sub-let it to the applicant. The amount of capital at his disposal will probably affect the decision of an applicant in considering whether he shall purchase the holding outright or work it under a tenancy agreement, but machinery is provided under a previous Act whereby the small holder who wishes to purchase the freehold of the property outright can pay off the purchase money by instalments. In this case the course of procedure is that the applicant pays not less than one-fifth of the purchase money at the start. One-quarter of the purchase money can, if the Council think fit, be secured by a perpetual rent charge, which would be in the nature of a small ground rent (it is possible, however, to redeem this rent charge by payment of a lump sum in the future if desired). The rest of the purchase money can be secured by a charge on the holding in favour of the Council, and this balance can either be repaid by half-yearly instalments of principal with interest or can be paid off in a lump sum at such time within the next 50 years, as may be agreed upon with the Council. It often happens that a grower when entering on the land considerably improves it by his initial outlay, and in such cases as this the Council has power, if it chooses, to postpone (for a period not exceeding five years) the time for payment of all or any part of the instalments of principal or interest above mentioned.

The Act also provides machinery whereby holdings may be worked on the co-operative system, and in this event the Council may relax the general rule that not more than one dwelling house shall be erected on any one holding.

The Act of 1892 provides that where a small holding is sold by the Council to an applicant, then, for a term of 20 years after the date of the sale, certain conditions may be imposed. These conditions include the following: (a) that any periodical payments due in respect of purchase money shall be duly made; (b) that the holding shall not be divided, sub-divided, assigned or underlet without the consent of the Council; (c) that the holding shall be cultivated by the occupier, and shall not be used for any purpose other than agriculture. However, in this case the expression "agriculture" includes "horticulture" and also the use of the land for any purpose of husbandry, including the keeping and breeding of live stock, culture of bees, and the growth of fruit, vegetables, and the like.

ALLOTMENTS.

Hitherto allotments have been dealt with by the Local Government Board, but their powers are now transferred to the Board of Agriculture, except as to certain powers relating to the financing of local authorities. Similarly the powers and duties of Rural District Councils are now transferred to Parish Councils, or, in cases where the district does not possess a Parish Council, then to the Parish Meeting. Up to the present time "allotments" have represented very small holdings which in fact did not exceed one acre, but the maximum size allowable under the Allotments Act of 1887 is now raised to five acres. A dwelling house may only be erected on an allotment if such allotment is one acre or more in extent, and in no case can more than one dwelling house be erected for occupation with any one allotment. It is the duty of County Councils to ascertain the extent to which there is a demand for allotments in their district, and to take steps to satisfy such demand. If the Board of Agriculture, after holding a local enquiry, considers that any County Council has failed to fulfil its obligations under the Allotments Act of 1890 the Board of Agriculture may transfer the powers of the County Council to the Small Holdings Commissioners.

GENERAL PROVISIONS.

The third part of the Act deals with the powers of the Council to purchase or hire land, compulsorily where necessary, in order to carry out the provisions of the Act, but in fixing the price no additional sum is to be paid to the owner of the land on account of the purchase or hiring being compulsory. Where a Council has hired land compulsorily for the purpose of small holdings or allotments the Council may, by giving to its landlord written notice not more than two years nor less than one year before the expiration of their tenancy, renew the tenancy for a further period (with the limits fixed by the Act) on the same terms and conditions as the original lease, and so on from time to time. A Council, however, has not power to acquire compulsorily land which forms part of any park, garden, or pleasure ground, or of the home farm attached to or usually occupied with the mansion, or which is otherwise acquired for the amenity or convenience of any dwelling house, or which is woodland not totally surrounded by or adjacent to land acquired by a Council under this Act, or which is required for certain public purposes as therein mentioned, and the Council cannot compulsorily acquire any holding which is 50 acres or less in extent. The Act also contains a somewhat novel provision to the effect that where a County Council acquires land for small holdings, and the labourers working on such land are thereby deprived of their employment and cannot obtain equally beneficial employment in the same locality, then the Council may pay to these labourers such sum as it thinks just by way of compensation for the consequent loss of employment and the expense of moving to another locality.

COMPENSATION FOR IMPROVEMENTS.

Hitherto we have only considered the position of an intending small holder when he enters on the land, but the Act also contains important provisions with regard to his right to compensation for improvements when he gives up his tenancy. The Act provides that where a Council has let a small holding or an allotment to a tenant he is to have, as against the Council, the right to compensation on quitting the holding for the following improvements:—(1) Planting of standard or other fruit trees permanently set out; (2) planting of fruit bushes permanently set out; (3) planting of Strawberry plants; (4) planting of Asparagus, Rhubarb, and other vegetable crops which continue productive for two or more years. It will be seen that the tenant thus gets similar privileges in this respect to those enjoyed by the ordinary market gardener (as distinct from a nurseryman), with, however, two important exceptions. First, no compensation is given for the erection or enlargement of buildings for trade purposes, and, secondly, the tenant is not to be entitled to compensation in respect of any such improvements if executed contrary to an express prohibition in writing by the Council; if, however, the tenant feels aggrieved by any such prohibition he may appeal to the Board of Agriculture, who may confirm, vary, or annul the prohibition, and the decision of the Board is final. Furthermore, a tenant of an allotment to which the Allotment Acts (as amended by this new Act) apply, may, if he prefer it, claim compensation for improvements under the Allotments and Cottage Gardens (Compensation for Crops) Act 1887, instead of under the Agricultural Holdings Act as above mentioned, and this right is given to him even in cases where the allotment exceeds two acres in extent.

Under the Compensation Act of 1887 just referred to the allotment holder is entitled on the determination of his tenancy, notwithstanding any agreement with his landlord to the contrary, to compensation for the following matters: (a) for crops, including fruit, growing upon the holding in the ordinary course of cultivation, and for fruit trees and fruit bushes growing thereon which have been planted by the tenant with the previous consent in writing of his landlord; (b) for labour expended upon and for manure applied to the holding since the taking of the last crop from time to time in anticipation of a future crop; (c) for drains and for any outbuildings, pigsties, fowlhouses, and for any other structural improvements made by the tenant upon his holding with the written consent of his landlord.

CONCLUSION.

Summing up the whole position, therefore, it will be seen that if any intending applicant wishes to acquire either by purchase or on lease a "small holding" exceeding one acre and not exceeding 50 acres, he should apply for further information to the clerk to the County Council for the district desired, or if he wishes to obtain an "allotment" not exceeding five acres in extent he should apply to the clerk to his Parish Council, or Parish Meeting, as the case may be. Should his application fail to meet with due attention or consideration, he should communicate with the Small Holdings Commissioners, care of the Board of Agriculture and Fisheries, 4, Whitehall Place, London, S.W.

Finally, a reminder on a few important matters may not be out of place from the practical point of view. First, an applicant should make certain that he can secure a market for his produce; secondly, he should decide definitely what he proposes to grow on his holding, and should make sure that the land proposed is suitable for the purpose. The secretary of the Royal Horticultural Society, Vincent Square, Westminster, would probably be happy to inform intending tenants as to where they could obtain the necessary advice for having the soil properly tested and analysed in order to insure that it is suitable for the purpose intended. Thirdly, one is bound to point out that by another Act passed this year the Board of Agriculture has power to order the destruction of any agricultural or horticultural crops or trees or bushes on which any insect, fungus, or other destructive pest may be found, or to which it may be likely to spread, and to do this without vouchsafing to the grower any compensation whatever. It is certainly unfortunate that the President of the Board of Agriculture should recently have found himself compelled to state that he could give no hope of any Act being passed which would enable compensation to be paid in these cases, and it is earnestly to be desired that on further consideration of the subject the Government may soon see its way to alter its decision on this point. *H. Morgan Veitch.*

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Artificial heat.—Amongst matters which militate against the well-being of Orchids under cultivation, perhaps the worst is the use of excessive artificial heat, and especially at this season, when the various departments devoted to these plants require more fire-heat than usual to maintain the desired temperatures. Nothing, in my experience, is more fatal to any class of plants, and especially Orchids, than excessive fire-heat at any time. A common mistake in the construction of Orchid houses lies in the neglecting to provide sufficient water pipes and boiler power. Another mistake is sometimes made in the massing of hot water pipes immediately beneath a thick slate moisture-holding stage, with the result that, in bad weather, the fires have to be driven and the pipes kept injuriously hot; whereas if the water pipes were more numerous and were equally distributed within a few inches of the ground, the heat of the pipes might be much less. The extra cost of more piping and the provision of a size larger boiler than is actually required is as nothing compared with the cost of fuel in endeavouring to maintain proper temperatures with insufficient heating surface. Of the many good types of boilers now on the market I prefer the sectional type; two of these are working highly satisfactory here, and have all the advantages claimed for them by the manufacturers.

Protection of houses.—In cases where the heating apparatus is not equal to the demands, much may be done in warm weather to reduce the strain imposed upon the boiler by a judicious use of protecting materials, such as Archangel mats, or waterproof canvas, rolled along the lower portion of the roof, and covering all

exposed glass ends and side of the houses. These coverings should be removed in the morning, when the atmospheric heat commences to rise, taking them to the boiler house, where they can be spread out and dried ready for use again.

Atmospheric conditions.—With regard to the atmospheric moisture at this season, commonsense and practice must regulate the operations of the cultivator, who must always bear in mind that it is necessary to maintain a correct balance of heat and moisture. Anything that tends to unduly excite the plants in any way should be strictly prevented, as all plants are now more or less inactive. Damping the floors, &c., is done once daily in this collection according to the atmosphere outside, this being done in the morning when the temperature has commenced to rise. In dry, windy, frosty weather, when much fire-heat becomes necessary, more damping of the paths and spaces beneath the water pipes is called for to counterbalance the consequent aridity.

Ventilation.—Although all Orchids delight in an abundance of fresh air, the ventilation may easily be overdone just now; but when the outside conditions are favourable, air may be admitted with advantage through the top ventilators, provided the method of arrangement is a good one. Continuous ventilation, worked independently on each side of span roofed houses, is far in advance of the lantern system, or small sashes lifting separately, the latter always leading to draughts. On windy days it is advisable to ventilate on the leeward side only, keeping the opposite ventilators closely shut. When the two sides lift simultaneously, as with the lantern system, this is obviously impossible. The lifting should be so arranged that the lights can be raised as little as half an inch if needed—a great advantage that up-to-date gearing possesses over the lever and pin arrangement, which is so often fixed in such a fashion that it is impossible to put on less than 2 inches of air at the first hole. The bottom ventilators may be carefully used at night during mild weather, and may often be opened in the daytime when it is not advisable to lift the top ones. At no time during winter do I advise that the top and bottom ventilators should be open simultaneously. The sense of feeling is the safest guide in the matter of heat, moisture, and air, and a little practice and observance will enable any cultivator to tell on entering the structure if the conditions obtaining therein are suitable for the plants.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

As the days are now lengthening, plants under glass will soon be starting into growth, especially stove and warm greenhouse Ferns, but as large plants in general are only repotted once in the year, it is necessary to avoid giving them a greater check than is necessary by that operation. In order to retard them, therefore, they should all be kept as dry at the roots at the present time as it is safe to keep them. By gradually withholding a little less water at each time of watering, the plant gets used to it, and when repotting takes place it does not feel the check so much, but afterwards starts into growth much quicker, rooting into the fresh soil quickly, as it were to compensate for the stinted measure of moisture it had been receiving. These little points in the cultivation of specimen plants have far more to do with the success of a plant developing perfectly than have great doses of some artificial manure. Attention to the minor details is the secret of the success of every prize-winner. The present time should be used in looking over all insect-infested plants in the stove, as no plant can thrive well with vermin on it. The cause of a great many of these pests upon the plants is bad or careless ventilation and syringing. At this time of the year, especially in Scotland, where we seldom see any sunshine, syringing should be done only on clear mornings at about 11 o'clock. Tepid water should be employed, and the operation should be carried out with care, not merely damping over the tops of the leaves of the plants, but syringing well underneath every leaf and stem of all plants liable to red spider and thrips, such as Codiæums (Crotons), Cordylines (Dracænas), &c. One good washing administered once or twice each week, according to the brightness of the weather, should be sufficient to keep the plants clean. Great care should be taken in not having the hot-water pipes too hot, as it is this kind of heat that is so liable to breed red spider and thrips. A little fresh air should be admitted to the stove after the plants have been syringed, even if the atmospheric temperature should fall a little, so long as the outside temperature is above 32°. Fresh air is of much importance in plant culture at all times of the year. When one considers the important part a leaf has to perform, it is clear that the greatest care should be taken to keep the foliage in a clean and healthy condition.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

At this season of the year the flower garden may be said to be without flowers, at the same time close attention is required during the winter months if good displays are to be realised in spring. Maintain a close observation upon the least robust of the spring flowering plants, and prevent them from suffering ill effects from frost, damp, insects, &c. For the purpose of affording a slight protection from frost it will be found that branches cut from Yew trees are very convenient in use, but they should only be employed with careful discretion. Well-screened coal ashes are valuable in some instances for sprinkling amongst herbaceous and Alpine plants, and may be supplemented with occasional dustings of air-slacked lime. We have found that additions of sharp sand or gravel to our adhesive soil answer admirably, favouring root-action, acting as a deterrent to insects, which not infrequently congregate amongst Alpine plants and their surroundings.

Helleborus niger (Christmas Rose).—The cultivation of this beautiful plant is simple in the extreme, but in order to secure pure-white flowers with a sufficient length of stem, some slight protection is necessary for a period of something like two months previous to gathering; such protection can best be afforded by placing frames over the plants. The plants thrive best in a deep, rich loam in a damp or rather shaded position. We cultivate the plants intended for supplying flowers for cutting, behind a north wall, and the roots are thickly covered with a mulch of rich manure from the time the plants finish flowering until they again need the protection of the frames, after which time cleaner and lighter stimulants are applied. For the purpose of increasing the stock, division of the roots, after flowering, may be recommended, but the plants thrive best if left for several years undisturbed. We have just counted, on a single plant occupying something like a square yard, 250 flowers in different stages of development.

Lawns.—The best appliance which I have yet employed to give the lawn a clean and tidy appearance at this season, after nearly all the leaves have been cleaned away, and after heavy falls of rain, which are followed by the increased disfigurement of the grass by worm-casts, is the motor lawn-mower, either with or without the cutting machinery. If the cutting appliance be removed the front wooden rollers should be removed also, replacing them with cast metal ones, thus giving the machine a more equal balance. If this mower is used at short intervals, and some well-slaked lime is freely applied once or even twice during the winter months before rain is expected, much benefit will result to the lawn.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to Lord ALDENHAM, Aldenham House, Elstree, Hertfordshire.

Arrangement of plots.—In order to become an efficient cultivator of vegetables, whether one has a large, medium, or small garden, it is necessary that many details be brought into practice and rigidly carried out each year. A plan should always be made of that part of the garden devoted to vegetable culture in which each plot is plainly depicted and the names of the various crops that are to be cultivated. It will then be possible to prepare each piece of ground so as to suit the requirements of the individual crop. If a proper system of rotation of crops is carried out, not only will they be much more satisfactory, but the expense of maintaining a kitchen garden in a condition to produce high-class results will be much diminished.

The seed list.—The selection of varieties from the seed list should be given very careful attention, and here I may be allowed to say that every gardener should be given the privilege of selecting his own stocks, as he is in a better position than any one else to know the requirements of the establishment. Varieties that are successful in one locality may be, and often are, a complete failure in another district. The cheap collections of seeds offered by the majority of seedsmen are, I am sure, of good value so far as quantity goes, but it must be remembered these almost invariably contain a large quantity of some seeds which one will hardly use and very little of those that will be most in demand. It is imperative that the best of everything be grown, as one can easily understand that inferior sorts require just as much if not more attention to cultivate them well as do the superior varieties; the extra cost in the first place is so small that it ought not to be considered. Good, standard kinds should always be grown for the main crops, but a few novelties may be included, as they afford opportunities for comparison with the older kinds, and whether they prove superior or not they are sure to be interesting. The work of selection can easily be carried out during the long winter evenings, and to the enthusiastic kitchen gardener will prove a labour of love.

Preparation of the ground.—This work is of paramount importance, but whether it shall be done during the autumn, mid-winter, or early spring must be determined by the nature of the ground and the state of the weather. The preparation of heavy land should, if possible, be left until February or March, but on light land the work can be done with advantage during autumn and mid-winter.

Trenching.—I am a strong advocate of deep cultivation, and am distinctly in favour of bringing the bottom spit to the surface, though I know full well that in this respect I differ from many good cultivators. I have always advised and practised it, and whenever possible move

the soil to a depth of from 2 feet 6 inches to 4 feet.

Manuring.—This operation requires the exercise of much discretion. Many crops will assimilate almost any quantity, while others are injured by its presence in the soil. Especially is this the case in very old gardens. Applications of lime, soot and wood ashes will often put new life into ground which has been a long time under cultivation, and at the same time destroy many destructive insect pests. My notes from week to week will be based upon my experience in this district, which is situated twelve miles north of London, so that some modifications must be allowed for by those who are in less or more favoured localities.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Vines in pots.—Where pot vines are being started to supply an early crop of fruit, the points of their canes should be brought down to a horizontal position in order to cause the buds to break regularly from top to bottom. The buds of young vines that have not been previously forced are usually stubborn about breaking into growth, and require a steady degree of warmth and humidity to cause them to do so. In cases where the pots are plunged, the heat of the material should be maintained at 75° to 80°. When growth has commenced sufficiently for the bunches of fruit to be seen,

the atmospheric temperature of the house (especially while the days are short and the external weather more than usually variable) should not be too strictly regulated. In early forcing it is a great mistake to insist on having fixed temperatures, irrespective of external conditions. Even in cases where ripe Grapes are required at as early a date as it is possible to get them, the forcing should be chiefly done in bright, mild weather, when the atmospheric temperature may safely be allowed to rise to 75° or 80° before the house is ventilated. On the contrary, there need be no hesitation during cold nights, in allowing the heat to fall to 55° or even lower. It is far better to do this than to force hard and continuously by maintaining a temperature of 60° at night, as is reasonable only in mild weather. Do not promote too much atmospheric moisture.

Late Vines.—Without a good season of rest, vines cannot remain long in vigorous health, and even the latest varieties, such as Lady Downes, Appley Towers, and Black Alicante, should now be cleared of their fruit, so that the energies of the plants may not be further exhausted. Sever the bunches with sufficient wood attached to them for the convenience of bottling, and carefully store them, in the usual manner, in the Grape room. Open all the ventilators in the vinery, and if the roots of the vines are contained in inside borders, let them be thoroughly soaked with water. The vines should be pruned without delay, and if this is done on the simple "close-spur" principle, shorten each lateral back to two prominent basal buds. Wash the woodwork of the house with hot, soapy water, and lime-wash the walls. In cleaning the vines, relieve their rods and spurs of any loose bark, and subsequently thoroughly wash them with a warm and moderately strong solution of the Gishurst Compound, working it well into the crevices by the aid of a soft brush. Should the vines be affected with mealy bug, it may be necessary to be more particular in removing all the loose bark, and the rods and stems, down to the uppermost roots, should be painted (avoiding the buds) with a thoroughly mixed compound composed of half a pint of coal tar, one wineglassful of paraffin, and nearly a gallon of soft water, with enough powdered clay added to make it of the consistency of paint. Complete these operations by removing the surface of the borders down to the top roots of the vines, and replacing it with a compost of loam, liberally mixed with crushed mortar rubble and wood ashes and a good sprinkling of bone meal or some approved fertiliser.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NEWSHAM, Warter Priory, Yorkshire.

Planting and transplanting.—Autumn is undoubtedly the best time for planting or transplanting fruit trees, always provided the soil at that season is in a proper condition for carrying out the work. Planting may, however, have been delayed from various causes, and where the soil is of a cold and clayey nature, it is often better to defer the operation until late in the spring. Those who have contemplated planting will have already ordered the trees, selected the site, and prepared the ground in the manner excellently described by the previous writer of this Calendar. No further delay need now occur when once the weather is favourable for the work. In gardens where there are many wall trees it is a good plan to purchase a few young maidens or two-year-old trees yearly, so that they may be trained to replace any that become worn out or that cease to crop satisfactorily. By this means changes may be effected without causing much difference in the supply of fruit, as such trees will come into full bearing at once. In replacing old wall trees, as much as 18 inches to 2 feet deep and 4 feet wide, of the old soil should be entirely removed. If the subsoil is cold and wet, some effective measures must be taken to provide good drainage by placing broken bricks and covering these with a layer of lime rubble. Cover the drainage material with turves, placing them grass-side downwards, and fill in with good roughly-chopped loam, or, failing this, with good garden soil, adding lime rubble and charred refuse to heavy soils, especially when planting stone fruits. No manure should be used at the time of planting. The work should be done carefully by skilled workmen; any extra labour bestowed at the time of planting will be well repaid later by fruitful trees. Prune all damaged roots and others that are extra long. Place the tree in position, and spread out the roots carefully at varying depths, working in amongst them some of the finer soil and making the whole quite firm as the work proceeds; the topmost roots should not be more than 3 inches below the surface. In planting Standard or Pyramid trees on heavy and wet ground, provision should always be made for drainage, and the soil should be well broken up, but there is little good to be got by trenching ground that is already too light for fruit trees. It is far better to apply from time to time rich manurial dressings on the surface. Extra deep or excessively rich borders cause young trees to produce gross roots, and these result in gross shoots, neither being any advantage to the cultivator. Trees that are received from distant nurseries should never be planted without being well puddled; this is done by standing the roots for some time in a tub containing stiff loam reduced to thick paste by the addition of water. All freshly-planted trees should be provided with stakes, and a permanent label attached to each. Mulch the trees with some litter or other material but do not employ animal manure.

PUBLIC PARKS AND GARDENS.

By JAMES WHITTON, Superintendent of the Parks and Open Spaces in the City of Glasgow.

The politics of park-management.—The important part which public parks and open spaces occupy in regard to the health and welfare of dwellers in crowded cities is so well recognised nowadays by municipal and urban authorities at home and abroad, that most cities and towns of any pretension have either a special department, or a committee, responsible for the establishment and maintenance of such establishments. As public parks and gardens, from their very nature, are part of a gardener's calling, and generally are, and always ought to be, managed by a properly-trained gardener, it naturally follows that the interests of both can be best served by their leading technical journals. It was, therefore, gratifying to those responsible for the care and management of public parks to read the editorial announcement on p. 5 of the first issue of the *Gardeners' Chronicle* for 1907 that a special feature was to be made of park interests. While the truths in the announcement were well and tersely put, the hope was expressed that the articles would prove valuable to those to whom they were to be specially addressed. If any fears existed in the editorial mind as to the success of the venture, such must have been quickly dispelled by the series of interesting articles by my friend, Mr. Pettigrew, whose management of the public parks and gardens of Cardiff is most commendable. To his articles I attribute a considerable increase in my correspondence during the past year on questions relating to the equipment and maintenance of parks. I have stated that the management of public parks ought to be in the hands of properly-trained gardeners. The fact remains, however, that in some places the responsible official hardly knows the difference between an Oak and an Elm, and consequently he has to depend on his subordinates for the technical details of the work. To one who is fairly familiar with the public parks of the principal cities of the United Kingdom, as well as with those of many continental towns, it is pleasant to be able to state that this point is being better realised by municipal authorities; and instead of the parks and open spaces being merely subordinated to the surveyor's department, they are forming separate parks departments, and appointing men as superintendents who are trained gardeners. As hardly any two towns are alike in their arrangement of work, the parks department in one may only be a sub-section of another, usually that of the surveyor's, or that of general health, whilst in another there may be a special parks committee.

PRICKLY PEAR. Few people in these latitudes are probably aware of the troublesome character of the Opuntia or Prickly Pear in the drier and hotter regions of the Southern Hemisphere. In South Africa a select committee has been appointed to consider the best means to secure its extirpation, and has recommended the Government to afford financial assistance in the matter. In Queensland matters have assumed an even more serious aspect, and the Government has offered a reward of £10,000 for the discovery of an efficient method of destroying the pest. The cost of clearing the Prickly Pear in this country is stated, by a writer in the *Queensland Agricultural Journal*, to vary between £5 and £15 per acre.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

Illustrations. *The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—
Sale of Dutch Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY AND FRIDAY—
Bulbs, Herbaceous Plants, Azaleas, &c., at 12; Roses at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—
Perennials and Border Plants, Bulbs, Tubers, Liliums, Carnations, &c., at 12; Roses in variety, at 1.30; Azaleas, Palms, and Plants, at 5; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
Imported and Established Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, January* 1 (6 P.M.) Max. 38°, Min 34°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, January* 2 (10 A.M.): Bar. 30·2; Temp. 35°; Weather—Fair.
PROVINCES.—*Wednesday, January* 1 (6 P.M.): Max. 42° Land's End; Min 33°, Scotland N.E.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—37·8°.

1908. In accordance with our usual practice, a sheet almanac is published with the present issue, containing all the horticultural events for 1908 for which the dates have been fixed at the time of going to press. In the cases of some Societies the fixtures are made at the annual meetings which take place in January, and therefore we are compelled reluctantly to omit their names from the calendar. To those secretaries who have kindly furnished us with particulars we desire to offer our thanks, whether or not the information they were in a position to afford was sufficiently definite for our purpose.

The fixtures are so far complete as to indicate that the year just commenced will be marked by great horticultural activity. The Temple and Holland Park Shows and the autumn exhibition of British-grown fruits will take place as usual, and the Royal Horticultural Society having quite got into the habit of holding fortnightly meetings during the winter months, instead of monthly meetings, as was the case formerly, will be concerned with as many events as its most enthusiastic members can reasonably expect.

Whilst writing on this subject, we may point out that meetings of the various committees have again been fixed in two instances for Tuesdays immediately following Bank Holidays. Complaints have been made again and again of the unnecessary inconvenience such meetings impose upon the members of the committees and exhibitors alike. Seeing that the services of the committees are purely honorary, the Council might reasonably be expected to favourably consider any representation the committees make on such a subject, and it was thought that the unanimous appeal made by the Floral Committee last August would have induced the Council to have modified the dates of such shows in the future. It may be argued that any particular member is not obliged to attend on certain days if his attendance would cause an unusual amount of personal inconvenience, but there can be no doubt that, from feelings of loyalty to duty, many of those whose personal desire would be to stay away, are, nevertheless, constrained to attend. We hope the Council may be induced to reconsider the question.

Several exhibitions of Colonial produce have been again provided for, and in respect to these we can only repeat our observations in a recent issue: namely, that if these shows are not to be made more attractive than they have been hitherto, the majority of the Fellows have no wish to witness them.

The National Rose Society will hold its annual Metropolitan exhibition in the Royal Botanical Gardens, Regent's Park, its autumn show in the Royal Horticultural Hall, and its provincial exhibition at Manchester.

The National Chrysanthemum Society will hold its exhibitions at the Crystal Palace as usual, but most of the remaining special societies, including the National Auricula, National Carnation, National Dahlia, and National Sweet Pea Societies, have arranged for their exhibitions to take place in the Royal Horticultural Hall.

The great provincial shows, such as those at Shrewsbury, Wolverhampton, York, Newcastle-on-Tyne, Hanley, and other places, will be held again this year, and the Yorkshire Gala will have special interest as marking the jubilee of the exhibition. The Midland Sweet Pea Society will hold its first annual exhibition at Wolverhampton, and several Midland societies, including the Midland Daffodil and Midland Carnation Societies, will again hold exhibitions in the Birmingham Botanical Gardens.

It will be noticed that spring shows, having Narcissus and Daffodils for their principal features, are becoming more numerous, and April is in consequence a greater exhibition month than it was formerly.

So far as can be estimated at present, the exhibitions of Chrysanthemums in November, 1908, are not likely to indicate any appreciable diminution in number.

The Franco-British Exhibition will be opened at Shepherd's Bush in May, and it is expected that horticulture will form an important feature at this exhibition during the summer months.

Outside the British Isles the most important horticultural event will be the show to be held at Ghent, which will extend from April 25 to May 2. The Ghent Quinquennials have always proved a great attraction for horticulturists not only in Britain but in almost all European countries as well, but that of 1908 will be specially memorable because it will mark the centenary year of the Société Royale d'Agriculture et de Botanique de Gand. There are 760 classes, divided into 29 groups, and in each class liberal prizes are offered. For new plants there are 20 classes; Orchids are invited to fill 82 classes, and as some of them are for large collections, there should be a magnificent display. In the 26th group there are 52 classes of a more or less scientific nature, and in these the exhibits will have some bearing upon the important questions of heredity, fixity of varieties, mutation, artificial selection, adaptation to environment, morphology, and many other important matters. The first list of invitations to assist upon the jury have already been issued.

Culture of Alpine Plants. Among the books recently published is one by Mr. Farrer* on the cultivation of Alpine plants in an English rock garden. It appeals directly and effectively to the specialist, who will spare no pains in acquiring an accurate knowledge of the accepted and named variations of the particular species, and in experimenting in a hundred and one ways to provide the cultural conditions best suited for each plant. We frankly confess that on opening this book and turning over its pages, our first feeling was one of irritation. Mr. Farrer rather seems to have expected to arouse some antagonism by his spelling and his mannerisms, judging from a few lines of his preface, so it will not come to him as a surprise to find he has partly succeeded. We shall not, we think, adopt his suggestions as to spelling reform, nor do we believe that he has scholarship on his side.

But when we have said this much and get into close quarters with the book, we have scarcely anything but praise. Mr. Farrer is an enthusiast, as anyone who gets keen on Alpine plants must be if he is worth his salt, and the little self revelations add an interest to the book to anyone who is fond of these gems of the floral world. Everybody who has explored moraine and peak for the plants themselves knows full well the sensation of suddenly coming upon a specially fine example of the objects of his quest often in the most inaccessible places. Anyone who has seen Eritrichium nestling in the crevices of the yellow south precipice of The Meige, or on the almost equally difficult faces of some of the Graian Mountains, must be dull if he does not get a little excited owing to the superiority of such a specimen over those growing in the scree below.

Mr. Farrer's claims to have enriched the literature of Alpine plants rests, however, on a basis more solid than that on which we have just lightly touched. The critical remarks as to specific distinction in, for example, the Saxifrages, will find an echo in the mind of all who have been entangled in them—and who, amongst those who care for Saxifrages, has escaped despair?—whilst his hints on many of the other difficult forms will be received with attention. He has himself travelled much, and some of the remarks on the plants in their native habitat strike us as very good. We note with pleasure that the author devotes a chapter to our English Alpines. Some of these are far more beautiful than many foreign species, whose chief claim to consideration often lies in mere

* *My Rock Garden*, by Reginald Farrer. London: Edwin Arnold, 1907.

rarity or high price. Some of our own plants require as much skill in their cultivation as the majority of those which hail from China, the Himalayas, or the Rocky Mountains. If anyone doubts this, let him experiment on Saxifraga oppositifolia for a few years; or let him try some of the Gentians, if he happens to live in one of the many districts in which it seems impossible to persuade them to flower as they ought to do. The excellent full-page illustrations form an attractive feature in a book which will be welcomed by all lovers of Alpine plants. There is much in it that is valuable and suggestive, and there is a refreshing absence of that dogmatism as to proper methods of culture, which, in the case of this class of plants, is never wise and is often futile.

former as Assistant Forest Officer in Cyprus, and Mr. DOWN, a member of the Kew gardening staff, as Agricultural Instructor and Assistant Superintendent of the Hope Gardens and Experiment Station, Jamaica. Mr. NOBLE holds the Diploma in Agriculture of the University of Aberdeen, and has studied forestry in France. The Secretary of State for India in Council, has appointed Mr. W. W. SMITH, M.A., Assistant to the Professor of Botany in the University of Edinburgh, as Curator of the Herbarium of the Royal Botani Gardens, Calcutta, in succession to Capt. A. T. GAGE, I.M.S.

"THE JOURNAL OF THE BOARD OF AGRICULTURE" for December contains an article upon the American Gooseberry-mildew, with special reference to its prevention or cure. It is urged that in the case of a badly-affected bush, which about one and a half million sterling. The botanical establishments in the various islands have played an important part in securing this result, both by distributing the plants and by affording information as to their culture, &c. Experimental stations have also been maintained by the Imperial Department of Agriculture, and these have become central points for giving information to cultivators in the various districts, and the authorities are also investigating the plants with the view of improving the yield of Cocoa both as to quality and quantity.

FAIRY RINGS. The unsightly appearance often produced in lawns and, occasionally also, in putting-greens, by the growth of the various species of fungi, which form "fairy rings," is so well known that any remedy which promises a chance

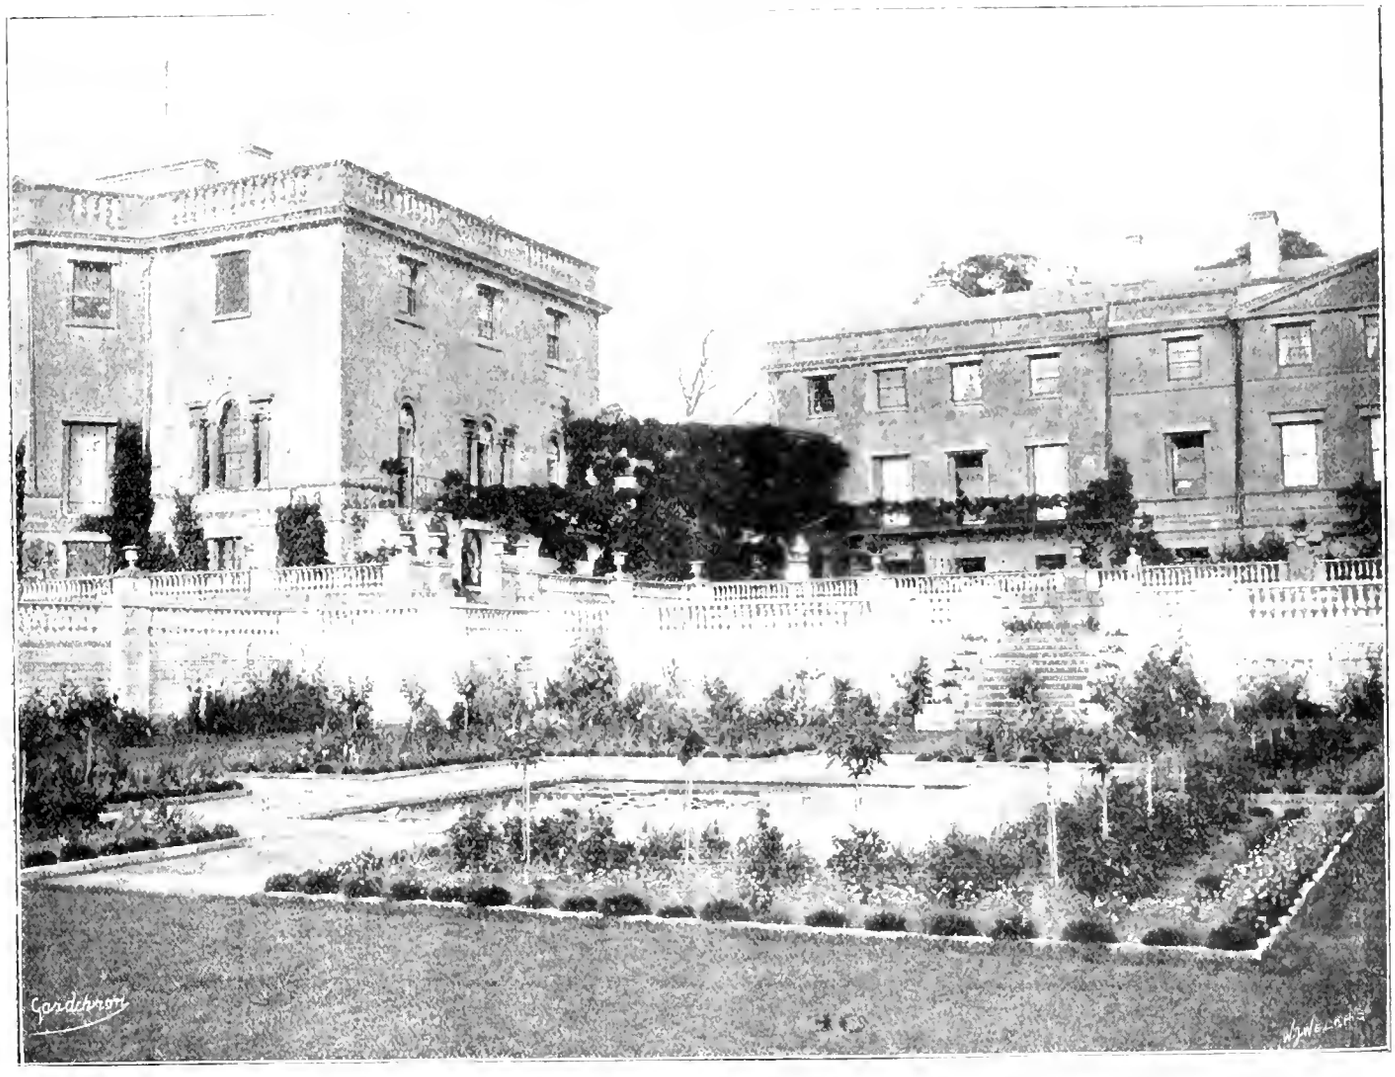

FIG. 10.—THE NYMPHÆA-GARDEN AT NUNEHAM PARK, THE RESIDENCE OF THE RT. HON. L. V. HARCOURT, M.P. (See p. 10).

SCIENTIFIC COMMITTEE.—In respect to the report of the last meeting of the R.H.S. Scientific Committee, Mr. FRED J. CHITTENDEN, secretary, has written us stating that in the seedless Apple, to which Mr. WORSDELL referred, the little structures at the "eye" end of the fruit were actual Apples, but only partially developed, and not only Apple-like structures as reported. The malformed fungus was a species of Tubaria, not Cribraria, as written in the report.

APPOINTMENTS ON THE RECOMMENDATION OF KEW.—We note in the *Kew Bulletin* (No 10, 1907) that Mr. CRAWFORD NOBLE and Mr. WILLIAM JAMES DOWN have been appointed by the Secretary of State for the Colonies, the ought to be removed and burnt, it should be first sprayed so as to avoid as far as possible spreading the infection by shaking off living spores. A coloured figure illustrates the appearance of the affected twigs in winter.

ROYAL GARDENERS' ORPHAN FUND.—The coming-of-age festival in aid of this charity will take place on Tuesday, May 12, at the Hotel Cecil, when the President of the fund, the Duke of BEDFORD, K.G., will preside.

"THE WEST INDIAN BULLETIN" (Vol. viii., No. 2) contains some interesting information on the Cocoa industry in those islands. In importance it ranks only second to sugar, the value of the exports in 1905-6 being estimated at

of success is worth a trial. Mr. G. H. ROBINSON, writing in the *Agricultural Gazette* (New South Wales), concerning "fairy rings" produced by a puff-ball, recommends sulphate of iron (green vitriol) dissolved at the rate of 8 lbs. in 30 gallons of water. This quantity is sufficient for 60 square yards. The ground should be well watered before the application, which should be repeated at weekly intervals three or four times. A week after the last application a dressing of freshly-slaked lime (1 ton per acre) must be given, and it should on no account be omitted, or the heavy dose of iron will produce injurious effects. The work is best done in autumn, as there is then less risk of injury to the Grass.

BIRMINGHAM SCIENTIFIC SOCIETY.—At a recent meeting of the Birmingham Scientific Society, held at the Midland Institute, Birmingham, an interesting paper on liverworts was given by Mr. T. H. RUSSELL. He explained that there were two kinds of liverworts—the foliose, or leafy liverwort, and the frondose, a variety which took the form of flat green fronds. The latter kind was often plentifully produced on the banks of streams, and was also to be found growing on the sides of wells. The foliose variety generally grew in shady moist spots, although some of them were more hardy, and flourished on rocks or trunks of trees. Mr. RUSSELL explained the close structural relationship between mosses and liverworts, pointing out that in a good many particulars the two came very near to one another. The most interesting cases of resemblance were to be found in some of the small mountain mosses, the capsules of which split open in a manner very similar to the method of the liverwort and quite different to the ordinary way of mosses. Mr. RUSSELL mentioned that the derivation of the name of the plant was somewhat curious. It received its name in far-off times, and was called liverwort because it was supposed to be a specific against liver complaint. This supposition was based upon the fact that some of the plants bore a resemblance to that organ of the body. The lecture was illustrated by about fifty lantern slides from original black and white drawings cleverly executed by the lecturer from specimens in his own collection.

ANNUAL DINNER OF NURSERY EMPLOYÉS.—At the invitation of Messrs. DICKSON & ROBINSON, Manchester, the members of the staff met at the Victoria Hotel recently, where an excellent dinner was provided, the remainder of the evening being given up to music and toasts. Mr. ROBINSON, the senior partner, replying to the toast of "The Firm," proposed by Mr. COMPSON, remarked the disastrous effect the bad weather of the closing year had had on the Grass and Clover crops in nearly every seed-producing country of the world, and stated that the Red Clover crop had been almost a failure. Its effect on the flowers of the garden was pointed out. As evidence of the existing good feeling between employer and employee and of its permanency, Mr. HICKS, in his toast "The Staff," alluded to the length of service of many now serving the firm; for instance, two 30 or more years, one 21, one 20, and several 13 to 20 years. Messrs. CLAYTON and WARD replied.

SEEDING OF ENGLISH ELM. The current number (10) of the *Kew Bulletin* contains an interesting note on the seeding of the English Elm. It is well known that although Ulmus campestris flowers freely in this country, it is generally believed to propagate itself solely by root suckers, and indeed its claim to rank as an indigenous tree has been disallowed partly on the ground of the infertility of its seeds in this country as contrasted with the readiness with which good seed is produced in France. But this year seedlings that were believed to be those of U. campestris were found in abundance in Lord RAYLEIGH'S grounds at Terling Place, Essex. Investigations showed, however, that they belonged to U. glabra, which is abundant in that neighbourhood. This species is hardly separable from U. campestris, and by some is regarded only as a varietal form, and the Terling Elm is said to be U. glabra with a certain leaning towards U. campestris. Seedlings of an Elm have also appeared in the grounds of King's College, Cambridge, which are believed to belong to U. campestris. Seedlings of the true plant, brought by Dr. AUG. HENRY from France, and germinated at Cambridge, indicate that there exists considerable diversity of appearance amongst the individuals derived from the same tree, and the leaves are hairy on both surfaces. A figure is given of the Terling seedlings, and also of a twig from one of those from Cambridge. The curious differences in the quality of timber in the Elm from different districts may be recalled here. Thus there is a variety in Buckinghamshire which is regarded as especially valuable for wheelwright purposes, for which it commands a high price. Perhaps it may turn out that these forms of the Elm represent mere varietal forms of one species, and are thus related to each other in the same sort of way as are the three forms of Cedar—Libani, Atlantica, and Deodara. The question of the mutual relationship of these varietal forms, and the causes on which their differences depend, are not only of scientific importance, but also of considerable economic interest.

GRAFTING CHRYSANTHEMUMS.—The remarkable results to be obtained by grafting the varieties of Chrysanthemum upon the vigorous species C. frutescens were well exemplified by a magnificent specimen of the variety Tokio exhibited at the Paris Chrysanthemum Show by Messrs. VILMORIN-ANDRIEUX this year. The plant, which was about 10 feet in diameter, bore between 700 and 800 blooms of fine quality. M. GASTON CLEMENT, writing in the *Revue Horticole*, gives an interesting account of the experiments that have been made in France on grafting Chrysanthemums, with especial reference to this latest production. The plant of C. frutescens, which formed the stock, was grown in a large tub, and was made to form a thick, clean stem of about a yard in height. At this point it was allowed to branch, and the stems were carefully pinched and stopped so as to form a symmetrical bush. The stock (which was four years old) was then grafted with 288 Chrysanthemum scions, the whole being accomplished in a single day last March by two skilful men. Complete union was established within 15 days, and the plant received no special care beyond that ordinarily bestowed on the Chrysanthemum, except, of course, that its large size rendered it necessary to shelter it from wind.

NUNEHAM PARK.

NOTWITHSTANDING the strenuous and responsible duties connected with a Parliamentary and social life, the Right Hon. L. V. Harcourt, M.P., the owner of Nuneham Park, Oxfordshire, has also succeeded in developing within a short space of time a very beautiful garden. The terraced Rose gardens, the Nymphæa-garden, the herbaceous-garden, the sundial-garden, and the swamp-garden are all interesting. Labels innumerable are seen, each of an indestructible type, so that one can walk and admire and make oneself familiar with the objects of attraction without continually appealing to a guide.

On the mansion itself, which occupies a commanding situation overlooking the River Thames, are growing such plants as Solanum Wendlandii, Leonotis Leonurus (at the time of my visit covered with its catkin-like orange flowers), Magnolia Campbellii, Ipomœa Learii, reaching a height of 20 feet, which flowered profusely last summer and perfectly withstood last winter's frosts; Azara integrifolia, Buddleia intermedia, Wistaria multijuga rosea, Tecoma speciosa, Wistaria fruticans, Ampelopsis Henryana which is quite distinct and has beautifully velvet-like, striped foliage; Passiflora racemosa, &c. In a narrow border on the south side I noticed the distinct grey foliage of Senecio Grayii and Citharexylum quadrangulare, reputed to be the fish-wood. On the western side of the house there are many uncommon wall creepers, including Bridgesia spicata, Wistaria chinensis noda, Stauntonia latifolia, Gelsemium sempervirens, Carpenteria californica, Edwardsia grandiflora, Schizophragma hydrangioides, Vitis Coignetiæ, and V. Thunbergii, Rhyncospermum jasminoides, &c. The walls of the mansion on the north side were planted with Lardizabala biternata, Lonicera caprifolium, Actinidia arguta, Solanum crispum, Wistaria fruticans, and Piptanthus nepalensis, which will some day become a most attractive feature.

The upper terraces extend along two sides of the mansion, and a broad path, some 200 yards in length, of mosaic paving of handsome and irregular design enhances the beauty of the surrounding flower borders. These beds, immediately in front of the mansion, are 10 in number, and each contains about 50 Rose plants of a distinct variety of colour; included are such varieties as La France, Frau Karl Druschki, General Schablikine, Grand Duc de Luxembourg, Caroline Testout, &c. The plants appear healthy and strong, and I was informed by Mr. Munday, the gardener, that each bed had been formed of new soil.

On the upper terrace are other beds of considerable size and geometrical design. One long border had been freely planted with Lilium speciosum magnificum, and, judging from the flower stems just removed, the plants must have flowered well. Ericas, Pernettyas, Choisya ternata, Andromeda floribunda, and Aster Amellus are also freely used here.

The lower Rose terrace is reached by about 11 steps: here there are eight Rose beds, each containing about 50 plants of such popular varieties as l'Idéal, François Dubreuil, Papa Gontier, Killarney, President Carnot, &c. The beds are edged with a broad band of Mrs. Sinkins Pink, while the beds and borders on the upper terraces have a broad edging of the old Crimson Clove Carnation.

Still another descent is made by 11 steps to the third terrace, which is known as

THE NYMPHÆA GARDEN.

Attractive and interesting as the Roses, &c., unquestionably are, one is compelled to linger here. This garden, or terrace, possesses exceptional interest in many ways. The central square pond contains some of Marliac's introductions. Four beds around the pond contained standard plants of Hydrangea paniculata grandiflora, these had flowered perfectly; the groundwork of these beds was planted with Andromeda japonica and floribunda, Kalmia latifolia, and Rhododendron præcox, bordered with Iris Victorine, Iris hispanica, mixed with Ixias and Armeria alpina. The walls on two sides were planted with such choice species as Ozothamnus rosmarinifolius, Medicago arborea, Adenocarpus anagyrus, Lomatia ferruginea, Cestrum Newellii and C. aurantiaca, Distylium racemosum, Sollya parviflora, Fabiana americana and F. imbricata, Hibbertia volubilis, Muehlenbeckia varians, Teucrium fruticans, &c.

In a line with the Nymphæa-garden terrace is the croquet or tennis lawn, which measures some 50 to 60 yards across. From this point a commanding view of the surroundings may be obtained, and looking across to the right as one faces the river it is evident more still remains to be seen, so we make our way to this new part by descending another flight of steps leading to a walk bounding the terraces. A wide herbaceous border extends parallel with this walk on the right, and to the left is a sloping bank to the park beyond, which has been beautified with Wichuraiana Roses of many kinds, creeping naturally over the ground surface, and a large bed of Rosa rugosa, Blanc Double de Coubert.

The continuation of this long path to the "wall-walk," which is about 11 chains in length, leads to the dell, water, pond, and swamp gardens. The wall has been built of stones placed flatwise; it extends round an elevated bank, and is an eminently successful piece of work. Here as elsewhere, the crevices of the stonework are planted with such suitable plants as Saxifragas, Sedums in variety, Campanulas, Alyssums, Acæna Buchanani, Acantholimon glumaceum, Veronica rupestris, Erinus alpinus, Opuntias in variety, Dianthus, Cerastiums, and other beautiful subjects. Immediately above the wall, which varies from 2 to 8 feet in height, a skilful piece of work has been executed at a point nearest the mansion, in the form of a novel sundial, some 15 yards in diameter, on the grass. On an inner circle, the Roman figures denoting the time are planted with Box on a groundwork of fine shingle; on an outer circle the following Latin motto is also neatly planted with Box—*Horas non numero nisi serenas;* the whole is novel, artistic and interesting. Hereabouts is a dividing hedge of Cistus ladaniferus, and if the plants succeed in attaining so large a size, and in flowering as freely, as they do in the south of England, they will form a pleasing and attractive feature.

It is necessary to return to the walled walk in order to reach the water garden; on the way a fine mass of Euphorbia Myrsinites is noted, and just beyond is a bed of Lilium longiflorum planted with 150 bulbs. On the left of this walk a broad herbaceous border contains a rich assortment of beautiful subjects, which have been arranged with great skill. I noted Agapanthus Mooreanus, Indigofera Gerardiana, Veronica Kirkii, Berberis Wallichiana, Andromeda Catesbæi, Styrax japonica, Coronilla Emerus, Othonnopsis fruticosum, Rubus lasiostylus, Cornus Kousa, Eleagnus longipes, Rhus Osbeckii, Magnolias, Ailanthus glandulosa pendulifera, Spiræas, Ribes, Weigela in groups, Rhododendrons, Buddleias, Cerasus of sorts, Crabs, Ilex, Liliums in variety, and close by a large bed of Gruss an Teplitz Rose, bordered with French Lavender.

On the right a path leads to the bowling green, and the entrance to the dell is reached by continuing along the "wall-walk." Here five large irregular beds are formed; one of these contain upwards of 150 Eremurus of sorts. Two beds are planted with Rhododendrons and Azaleas and the others with ornamental and deciduous plants and trees, which include Spiræa Aitchisonii, Myrica californica, Juglans cordiformis, Prunus Carohniana, Viburnum macrocephalum and Sieboldii, and Lycium europæum. Another bed contained Andromeda nitida, Menziesia prolifera alba, Abelia rupestris, Carmichaelia australis, Vitex Agnus-castus, Digitalis ambigua, and Senecio compactum. These beds are divided by a grass walk 15 feet wide and bordered with Lavender, and an avenue of pink-flowered Almond trees. On the north side of this lovely dell many choice shrubs are planted, totalling over 100 kinds; they are such as Cassinia fulvida, Romneya Coulteri, Pittospormum Tobira, Eucalyptus urnigera, Azara Gilliesii, Nevinsia alabamensis, Raphiolepis japonica ovata, Eriobotrya japonica, Coronilla Emerus, Caragana aurantiaca pygmea, Eucalyptus Gunnii, Stuartia pentagyna, Daphniphyllum glaucescens, Xanthoceros sorbifolia, Crinodendron Hookeri, Corylus maxima purpurea, and many others, which will give a constant succession of floral and foliage display. Near at hand is a border containing about 50 tree Pæonies backed with Aucuba japonica variegata; clumps of Rhododendron "Pink Pearl" are close by, the whole forming, when in flower, an enchanting picture. *W. H. C.*

(To be continued.)

A LITTLE-KNOWN ACACIA.

WE reproduce a figure of Acacia podalyrifolia, a plant the sprays of which are just now being sold in the Covent Garden market. It is, without doubt, one of the most beautiful of the Acacias, and the contrast between the yellow colour of the blossoms and the powdery, glaucous hue of the conspicuous and rather leathery leaves (phyllodes) is most effective. The flowers are very sweet scented, and for decorative purposes this Acacia deserves to rank high in the public esteem. The species, like so many others of the genus, is of Australian origin, and, although it is now being imported from the South of Europe, it is still looked on as an uncommon plant in our markets.

FIG. 11.—ACACIA PODALYRIFOLIA, A SPECIES IMPORTED TO COVENT GARDEN MARKET.

AMERICAN NOTES.

CHRYSANTHEMUMS.—Much of the dissatisfaction shown in America with English and Continental-raised novelties in Chrysanthemums arises from the long neck or bare stem that is produced when a crown bud is taken. The ideal commercial kind must be clothed with leaves well up to the flower, and have a stiff stem that is capable of carrying the flower erect. Clear telling yellows, whites, and reds are most in demand.

OBITUARY.—The lamented death of P. J. Hauswirth, of Chicago, the popular secretary of the Society of American Florists, and one of the best known men in the trade, under peculiarly painful circumstances, has caused a widespread feeling of regret. He was so universally liked that there is not a city of any size in the Union but has someone who will mourn his loss and miss his genial presence. Just 20 years ago he was elected financial secretary of the Chicago Florists' Club.

CARNATIONS.—"Keep their heads cool and their feet warm," writes a successful Carnation propagator, when referring to cuttings cultivated on benches. Among the best of the newer Carnations is the bright red seedling G. P. Bassett. It is a grand, showy bloom, and, as growing in Messrs. Bassett and Washburn's fine plant house at Hinsdale, Illinois, shows its excellence as a commercial variety. It thrives admirably under the ordinary benching treatment as practised here, and the only drawback, according to English ideas, would be the somewhat severely serrated petals. Defiance, a grand seedling, raised by Mr. W. N. Rudd, is better in this respect, and is in every way worthy of this noted raiser. Although White Enchantress finds many admirers, White Perfection is certainly the finest white variety to date. Lucille, tinted white, is a lovely flower, and the new Lawson Enchantress, a variety with Enchantress habit and Lawson colour, is a coming sort. It has not been as widely advertised as some others, but it has excellent qualities [illegible]

NOTICES OF BOOKS.

*TREES AND THEIR LIFE HISTORIES.

THE awakening interest in trees and forestry is shown in the recent appearance of several books on the subject. Some of them, full of valuable information, are yet disappointing owing to the absence of arrangement upon any definite plan, scientific or practical, thus making it difficult work for those who consult them in the hopes of making sure of identifications. Others again, while better arranged, are intended more as guides to the sylviculturist who is growing trees to be treated as a crop, rather than to the arboriculturist who grows them for their beauty and for the pleasure they give him in watching them grow. Mr. Groom's book is neither of these: the arrangement is scientific and yet easy to follow, while the practical advice is reduced to careful definite statements put as briefly and concisely as possible. Instead of having, let us say, the Mountain Ash sandwiched between the Yew and the Horse Chestnut, we have all the important members of the family Rosaceæ brought together, and their appearance, growth, and requirements easily contrasted. In the preface to his book, Mr. Groom says: "I have endeavoured to consider the tree, not as a mere object to be identified, but as a living being whose struggling life is to be watched, whose wants are to be studied and whose changing lineaments are to be observed." And thus he has, very rightly in our opinion, confined himself to the study of the indigenous British trees and large shrubs, with the addition of merely the most important and most common of introduced species. Each species is studied not only in its state of flower, summer leaf-expanse and fruit, but in its winter aspect, when, for deciduous species at any rate, there is little to help in identification but the twigs, the bark, and the resting buds. All these characteristics are represented in a series of admirable illustrations from photographs which show bark, resting buds, winter twigs, opening buds and young leaves, flowers and fruit, and give as well, in most cases, and certainly for all the most important kinds, full-page pictures of the same tree in its winter and summer aspect, taken from the same point of view and placed in the book opposite each other. We venture to think that such an arrangement may be of great use to the artist who has to paint a landscape and is glad to be able to prepare his skeleton trees beforehand and then clothe them with leaves just as the painter of draped figures goes to work. For an example, we may point to figs. 251 and 252 (the Beech) or to 373 and 374 (the Horse Chestnut), both admirable examples of the disposition of branches and twigs, and the appearance of the same when covered with their summer foliage. The number of really indigenous British trees and shrubs, such as Mr. Groom has admitted to his work, is, we estimate, only 42, of which the Poplar and Willows account for 10 and the Rosaceæ for nine species. To these Mr. Groom has added, of course, those species which, like the Spruce, Silver Fir, and Larch among Conifers, and the Elm, Sweet Chestnut, Horse Chestnut, Black Poplar, Sycamore, Norway Maple, and Plane among broad-leaved trees, have been at some time or other introduced and have more or less established themselves here. And he has also included, especially among Conifers, some of the foreigners which are most commonly met with in parks and gardens, and among them we find the Cedar, Sequoia (Wellingtonia), Araucaria imbricata, several species of Pine, the Douglas Spruce, and the Evergreen Oak. Mr. Groom has done well to go no further: it would only have complicated his work, and he must have found it more difficult to restrain himself than to yield to the wish to mention just one or two other popular favourites. This work is sure to be popular with those who can afford it. A little more information regarding the geographical distribution of each species and the kinds of soil they thrive best upon would have been useful.

* By Percy Groom, M.A., D.Sc.; illustrated by photographs by Henry Irving. (Cassell & Co.)

PLANT NOTES.

LUCULIA GRATISSIMA.

IT was interesting to see this useful greenhouse plant so well shown at a recent meeting of the Royal Horticultural Society. Its propagation is a difficult matter unless properly understood. I have raised a good many seedlings, but have lost most of them before they flowered. My experience has been more favourable with cuttings, but even these require very careful treatment. The best cuttings are those obtained from fairly well ripened shoots, which should be taken early in the year. They must be cut off quite close below a joint (or pair of leaves), and a slight split made upwards between the two basal leaves, which, of course, are removed. The cuttings may be put into any light, sandy loam, and only just deep enough to keep them firm. I have been most successful when I have fixed them to a stick to hold them up, and put the ends of the cuttings in only just below the surface. They root best where there is a good bottom heat and a cool surface.

FIG. 12.—LUCULIA GRATISSIMA. A FRAGRANT GREENHOUSE PLANT: COLOUR OF FLOWERS PINK.

After the plants have made roots they require some care in potting, for the Luculia is a plant that must not have its stem buried, and the fine, thread-like roots may be easily damaged. Make the soil moderately firm, and be sure to employ plenty of drainage material. The compost should be used when neither too dry nor wet enough to clog together.

Many of the best plants of this species have been lost, or neglected, through failures which have been chiefly caused by the use of shading and too much artificial heat.

The Luculia was introduced somewhere about 1822 or 1823, and this was the time when the heating of greenhouses on improved methods was making headway. In looking up the date, I am reminded of one of my oldest friends, the late Mr. E. Spary, of Brighton, who was one of the first to superintend a saddle boiler for the heating of greenhouses, and, though a very old man when I first knew him, he gave me much useful information. *A. H.*

LILY BULBS FROM JAPAN.

As may be seen by the advertising columns of the *Gardeners' Chronicle* immense numbers of Lily bulbs are sent to this country from Japan during the late autumn and winter months. Were it not for these importations some of the species would soon become exceedingly rare, as they are by no means easy of cultivation—at least, in Western Europe. A notable example is Lilium Krameri, while Lilium auratum is in many districts, at least, extremely difficult to establish. One hears of individual successes with L. auratum, but, despite this, the fact remains that it is quite impossible to purchase home-grown bulbs in considerable quantities.

By this expression I do not mean bulbs imported one year, planted in England, and lifted in the following season, as such bulbs can by no means be considered as grown in this country. We must still look to Japan to maintain for us a supply of this magnificent Lily, for it does not appear likely that other countries will send us consignments of L. auratum, as they have done in the case of Lilium longiflorum. Whether it be from Lily fungus, sunstroke, or some other cause, L. auratum is a capricious Lily, and when the boxes sent from Japan are opened here, it is found that the mortality among the bulbs on the voyage is much greater than in the case of L. longiflorum or L. speciosum, which are also imported in very large numbers. Beside the ordinary form, we get limited consignments of that extraordinary variety of L. auratum known as platyphyllum or macranthum, some of the bulbs of which are very large.

Two beautiful and distinct varieties are virginale or Wittei, the spotless purity of whose blossoms is only relieved by a yellow band down the centre of each petal, and rubro-vittatum, in which that band is of a deep crimson hue. Compared with the others, the bulbs of these two varieties are small, but, as a rule, they flower well.

Lilium longiflorum naturally goes to rest, and also starts its growth earlier than the other

species, so that the bulbs of this species are the first to arrive here. They are much sought after, being purchased in very large numbers for retarding purposes, by which process it is possible to have flowers of this species all the year round. Most of those sent from Japan as the typical L. longiflorum consist of a very superior form, almost, if not quite, identical with that known as Wilsonii. Other varieties are grandiflorum and Takesima, characterised by dark-coloured stems, while the exterior of the flower buds is tinged with purple.

Lilium speciosum, which usually arrives in splendid condition, is also as amenable to retarding processes as is L. longiflorum. The bulk of the white-flowered forms we get from Japan consist of the variety Krætzeri, which, though often referred to as album, is quite distinct from the true album. This last is largely grown by the Dutch, and has dark-coloured bulbs, while the stems and unopened buds are heavily tinged with chocolate. The bulbs of L. Krætzeri, on the contrary, are of a yellowish hue, the stems and buds green, while even the expanded blooms have a greenish tinge towards the centre. The pollen of this flower is of a dark brown colour, but occasionally mixed with the bulbs of L. Krætzeri is a form whose flowers have bright yellow pollen. This, known as album novum, is a white-flowered counterpart of the variety punctatum, which, though grown by the Dutch, never, as far as I am aware, crops up among these Japanese importations.

Of the coloured kinds, most of the bulbs are disposed of as rubrum. They consist principally of a decidedly superior form, to which the name of rubrum superbum is often applied. Interspersed with them are frequently bulbs of the variety Melpomene, the richest coloured of all the varieties of L. speciosum, the brightness of whose colouring is further enhanced by the almost white margin to the segments. In this variety the bulbs show a greater tendency to break up into several crowns than in any other kind. So marked is this feature that it is quite possible for anyone well acquainted with these Lilies to select a good percentage of the true Melpomene, even when mixed with the other forms.

Although the bulk of the Lilies we receive from Japan consists of the three species above named, yet there are many others sent here from the "England of the East" in greater or lesser numbers.

Chief among them are L. tigrinum, most of the bulbs of which are characterised by their immense size. As a rule, they consist chiefly of the variety Fortunei, with very woolly stems, and rather pale-coloured flowers, disposed in a large pyramidal-shaped head. Though these flower magnificently the first season after importation, their strength is so much exhausted that they take some time to recover.

Other Lilies that reach this country from Japan, usually in very limited numbers, are Lilium Alexandrae, known sometimes as L. Ukeyuri, L. Batemannæ, L. concolor × L. c. Coridion, L. cordifolium, L. Hansonii, L. Krameri, L. Leichtlinii, L. Maximowiczii, L. odorum, and L. rubellum. Several choice forms of L. elegans also arrive here, but, in addition to these, we get many varieties from the bulb cultivators of Holland.

While the importations of L. longiflorum and L. speciosum from Japan have greatly increased within the last ten years, the more uncommon Lilies are not sent in such numbers as they were formerly. *W.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

TRIALS BY THE ROYAL HORTICULTURAL SOCIETY.—During an informal talk recently amongst members of the Fruit and Vegetable Committee it was suggested that the respective varieties of Asparagus might form the subject of a very desirable trial at Wisley, the deep sand there being well suited to the culture of that plant. One single row of 18 or 20 plants of each variety would suffice. This would constitute practically a permanent trial. Bundles of cut heads of each could be shown to the Committee in the spring at Westminster, and that body could see the plants in the autumn in order to examine their growths and general characteristics. A further suggestion was made that, apart from any ordinary trial of new varieties of Potatos, one to determine the effects of seed change in relation to place of growth should also be carried out. Experiments in other places have shown that very different results are obtained from Irish, Scotch, Midland, and Southern grown seed. For the Fellows of the Royal Horticultural Society such information would be invaluable. *D.*

NERINE BOWDENII.—This new species, illustrated in the *Gardeners' Chronicle*, November 26, 1904, p. 365, proves to be the best of the late-flowering Nerines, and it should be grown extensively for decorative purposes. Four plants of it which have been in bloom with me for some time past were still in flower on Christmas Day, and their large heads of pink flowers were very effective. There are two distinct forms, the one with the broader segments being the dwarfer, and, some would say, the better variety, although that with narrower and longer petals is an elegant form. This species is one of the most robust and floriferous of the Nerines, merely requiring to be grown in a cool greenhouse, pit, or conservatory. *J. O'B., Harrow.*

ECCREMOCARPUS SCABER.—A plant of Eccremocarpus scaber used to grow on the walls of the gardener's house at Burghley House, Stamford, and possibly it, or some descendant of it, may still find a place on the walls. This plant used to flower profusely every year, and its seeds were scattered round about, and germinated freely. It was there during the time the late Richard Gilbert was gardener at that place, and it had become quite naturalised. Two hundred miles and more south of Stamford, near the Dorsetshire coast, I had a plant of it on the front (south) wall of a vinery. It had also become naturalised, and flowered freely. It was not much of a seed-bearer however, unless artificially pollinated, and then only to a small extent. This plant was never protected in any way, although it undoubtedly derived some warmth from the heating apparatus of the vinery, which served as a plant stove in the winter months, the vines being withdrawn to the outside at that season. Treated as an annual, Eccremocarpus scaber is a pretty plant and well worthy of a place on a warm wall, or it may be allowed to trail over Pea sticks or small shrubs, the colour of the flowers—deep yellow—being uncommon among hardy climbers. Eccremocarpus belongs to the natural order, Bignoniaceæ, and it could, as the late F. W. Burbidge advised in his *Cultivated Plants*, be grafted on Catalpa syringifolia, a species belonging to the same order. Like all Bignonias and Tecomas, the Catalpa is readily increased by root cuttings, put in the late winter months, in a slight bottom heat. The grafting should be undertaken in a close, warm case in the propagating house, employing one-year-old mature shoots as the scions. *F. M.*

A PROPOSED VEGETABLE EXHIBITION.—The disappearance of the National Potato Society from the list of special horticultural or gardening societies leaves the course clear for the creation, if it be desired, of a national society for the promotion of the culture of vegetables generally, and Potatos especially. All vegetables have great value as food, and their culture and improvement merit the widest encouragement, and in any exhibition they help to create a very attractive variety that Potatos alone cannot give. They have for the seed trade a very special importance, as nearly all the kinds in cultivation have to be raised from seeds. Any national exhibition must largely depend for its prizes and support on the liberality of the members of the seed trade, but no objection can be taken to such dependence, provided each seed firm recognises to the full the fact that the objects of any such exhibition are general, and not local nor personal. At Shrewsbury and other large provincial exhibitions of vegetables may be seen the wonderfully attractive nature of good vegetables, and the liberality of the seed trade in promoting such displays. It is not merely that at such shows vegetables make remarkable displays, but that they are doing very much to popularise their culture, and to show which are the best kinds or varieties. Almost everywhere in the provinces do we see superb displays of vegetables in their seasons. There is nothing of the kind in London, although were a society specially formed to promote a great exhibition of vegetables in the Horticultural Hall in the autumn of each year, we ought to have something much finer and more comprehensive than any provincial show can provide. One weakness of ordinary vegetable competitions is that the numbers of varieties or kinds in a class being limited, each cultivator merely duplicates just a few of the most attractive. If a large class of, say, 18 to 24 dishes be included in a collection, then almost every known garden vegetable finds inclusion. Where only classes for six or nine dishes are provided, certain kinds should be specified for such class or classes, and other classes for equal numbers of kinds provided, from which all previous named kinds be excluded. That would enable the so-called "interior" vegetables to find a place at any exhibition. Salads, as a rule, are best excluded from classes, the kinds forming which are used for cooking. Herbs also need encouragement, and rather than be shown in bunches should be shown as single, well-grown plants in pots. Necessarily the Potato, being a primary vegetable product, exhibitions would have to be held in the autumn, although not necessarily at the same time each year, to enable the Potatos to be exhibited at their best. The month of August in one year would be suitable for early varieties of Potatos or other vegetables, and October in alternate years would suit late ones. This variation in the times of the competitions would no doubt help to introduce diverse competitors from year to year. *A. D.*

SHOULD POINTS BE AWARDED IN JUDGING FRUITS OR VEGETABLES?—When visiting some of our leading horticultural shows, the question has occurred to me whether there is any real value in awarding points to exhibits. At this time of the year, when new schedules are being drawn up, could not something be done to settle the matter? It is questionable whether the present system of pointing is of any real value at any exhibition, whether the exhibits to be judged are groups of plants, fruit, or vegetables. Does not the present system deter the young grower, rather than encourage him to compete? *Hortus.*

ANEMONE ST. BRIGID'S STRAIN.—At the time of writing (December 26), these are in full bloom out-of-doors. They may be had in bloom all the year round by making sowings at different seasons; they are easy of cultivation, and will grow in any good garden soil, being specially well suited for the herbaceous border. The plants now blooming have been raised from seeds sown last May, having been saved in the previous summer. To maintain a succession of bloom, seeds need to be sown in spring, summer, and autumn; being perfectly hardy they require no covering in the severest weather. The seeds should be sown moderately thickly, and the seedlings thinned out as may be required. They are best when sown in a bed or mass to produce an effect. When sown in the autumn, a few wood ashes should be placed over the bed to keep the heavy rains from making the surface soil too hard. Anemone King of the Scarlets does not seed so freely as the St. Brigid's Strain, but for cultivation in pots it is one of the most useful. Rabbits are very fond of the tops of these Anemones, and will soon make havoc among them if not protected in winter. *A. B. Wadds, Paddockhurst Gardens, Sussex.*

CEANOTHUS AZUREUS.—This species is perfectly hardy in gardens in this locality and planted in all aspects. The flowers, which are pale blue, are produced from June to August. I have never known it to be affected by the cold of winter. In these gardens is a specimen, 30 or 35 feet high, planted in the pleasure grounds in a cold, damp corner. This tree is probably 50 years old. *G., Newtown Park House Gardens, Blackrock.*

SOCIETIES.

ROYAL HORTICULTURAL.

DECEMBER 31, 1907.—The last meeting of the Society for the year now past took place on the above date at the Society's Hall, Vincent Square, and it was remarkable for the paucity of the exhibits and the poor attendance on the part of Fellows of the Society and the general public. The weather was cold and sunless, although the hall itself was warm enough for personal comfort and for the safeguarding of the warm-house plants, including some exhibits of Orchids.

Floral Committee.

Present: W. Marshall, Esq. (chairman), and Messrs. Henry B. May, Jas. Walker, Jas. Hudson, Ed. Mawley, T. W. Turner, Herbert J. Cutbush, Chas. Blick, W. Howe, J. F. McLeod, Walter T. Ware, W. Bain, Chas. Dixon, Arthur Turner, Jas. Douglas, Charles E. Shea, W. P. Thomson, E. H. Jenkins, George Paul, R. C. Notcutt, and R. Hooper Pearson.

The exhibits from Messrs. J. VEITCH & SONS consisted of groups of winter-flowering Begonias, hybrids of B. socotrana and other species, but in every case the first-named species was employed in the crossings with large, late-flowering, tuberous varieties. The crosses shown on this occasion were extremely floriferous, and possessed pleasing tints. They consisted of Latona, pale red fading almost to white in the centre, and, unlike the others, having single flowers; Winter Cheer, Mrs. Heal, Julius (a fine rose-pink, with double and partially double blooms), Ensign (of a rosy carmine colour, mostly double-flowered, and the plant reaching a height of 2 feet, with ample leafage). Other plants were Pavonia × kermesina, having terminal corymbs of crimson-coloured flowers of a highly decorative character, and bright green, lanceolate leaves; the showy Calceolaria Burbidgei, Leonotis Leonorus, Moschosma riparium, a South African plant having loosely-arranged spikes of small, white blossoms; Jacobinias coccinea and chrysostoma, Coleus thyrsoides, and Exacum macranthum, both blue-flowered and most useful decorative plants in the winter season. As foils to the flowering subjects various species of Ferns were intermixed with these. A plant of Cotoneaster Franchettii, bearing a good crop of coral red berries, was likewise shown. (Silver-Gilt Flora Medal.)

The other side of the table was occupied by a mixed collection of plants and cut flowers from Messrs. HUGH LOW & Co., the Royal Nurseries, Bush Hill Park, Middlesex, among which were remarked the new, scarlet-flowered Carnation Beacon, bright in its tint and very double in form; pink-flowered Enchantress, and the rose-coloured variety of that name; also Robert Craig; Aristocrat (new), White Perfection, and a few other Carnations. Of the rest, we may mention some new strains of Cyclamens and a group of small plants of Euphorbia jacquiniæflora, some bush Oranges, and, arranged on the floor, a group of well-grown Dracæna Doucetti and D. Dallieri, both excellent decorative plants (Silver Flora Medal.)

A fine display was made by Messrs. CANNELL & SONS, Swanley, with bunches of flowers of Zonal Pelargoniums in single and double-flowered varieties. (Silver-Gilt Banksian Medal.)

Several small groups of plants were shown by Messrs. H. B. MAY & SONS, nurserymen, Upper Edmonton. These consisted of Euphorbia jacquiniæflora, Carnation Snowflake, three varieties of Poinsettia pulcherrima, a few plants of Indian Azaleas, and a considerable group of Dracæna "His Majesty," having broad, richly-coloured leaves; a good decorative variety. (Silver Flora Medal.)

Carnations as plants and cut blooms were shown by Messrs. W. CUTBUSH & SON, of Highgate and Barnet. There were noted the varieties Robert Craig, Mrs. S. J. Brooks, The Mikado, Britannia, Jessica, Marmion (a big flower, having crimson splashes on a white ground), the variegated Lawson, Harlowarden, and others. This firm also exhibited a miscellaneous assortment of such subjects as Pernettya mucronata in variety, bush Oranges, Poinsettia pulcherrima, Skimmia japonica, Daphne japonica, Ferns, small Palms, Iris alata, &c. (Silver-Gilt Banksian Medal.)

Messrs. J. PEED & SON, nurserymen, West Norwood, exhibited Alpine plants in much variety; these were growing in pots and large pans. (Silver Banksian Medal.)

For a large vigorous clump of Sarracenia purpurea, taken from the open ground, and furnished with numerous pitchers, Mr. W. A. Cook (gr. to Sir E. LODER, Bart., Leonardslee, Horsham), was awarded a Bronze Flora Medal.

AWARD OF MERIT.

Primula obconica, "*Hayes Place Double*."—E. A. HAMBRO, Esq., of Hayes Place, Hayes, Kent (gr. Mr. J. Grandfield), exhibited several varieties of Primula obconica, and an Award of Merit was granted to the variety "Hayes Place Double."

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. secretary), Harry J. Veitch, De B. Crawshay, W. Boxall, F. J. Hanbury, J. Charlesworth, H. G. Alexander, W. H. Young, J. Wilson Potter, W. H. White, H. A. Tracy, T. W. Bond, A. Dye, H. T. Pitt, W. Thompson, A. A. McBean, and H. Little.

Messrs. JAS. CYPHER & SONS, Exotic Nurseries, Queen's Road, Cheltenham, staged a very nice group, in which all the plants were excellently well grown and flowered, and for which a Silver Flora Medal was awarded. The central plant was a very good specimen of Miltonia Blenana nobilior, with two spikes of its large white and pink flowers. Behind were arranged a selection of varieties of Lælia anceps, including the large and finely-coloured L. a. Chamberlainiana, L. a. Amesiana, L. a. Percivaliana, L. a. Hillii, and others. A pleasing effect was made by arranging with these the white Lælia autumnalis alba and the graceful and now rare L. Gouldiana. The rest of the group was of Calanthe Veitchi superba, C. Wm. Murray, and a good selection of Cypripediums, among which were C. Troilus var. Nogii, with a fine dorsal sepal having an even band of white at the edge; C. Charlesianum, Cypher's variety, a very bold flower; a selection of good yellow varieties of C. insigne, and a pretty new hybrid between C. hirsutissimum and C. Mons de Curte.

Messrs. MOORE, LTD., Rawdon, Leeds, were awarded a Silver Banksian Medal for a group of Cypripediums, the best of which were C. Boadicea majesticum, a very fine hybrid, with a good white and rose dorsal sepal and very dark-coloured petals and lip; C. insigne McNabianum, very freely developed, the large chocolate-purple blotches on the upper sepal being joined together, and changing to purple towards the clear white margin; C. aureum virginale and C. aureum delicatum, two fine light-coloured forms; a pretty light form of C. Niobe; C. Leeanum Imperator, a well-defined and attractive variety; C. Phædra, with a fine rose-purple dorsal sepal; and several unnamed hybrids.

Messrs. HUGH LOW & Co., Enfield, staged a group, for which a Silver Banksian Medal was awarded. The central plant was a very fine specimen of Cypripedium Mrs. Wm. Mostyn, with unusually flat and well-developed dorsal sepal, which is deep rose-purple, with a white margin. Also noted were good C. insigne Harefield Hall, and other forms of C. insigne; C. Adrastus Mariæ, with a very finely-coloured flower; C. Ville de Paris, the largest of the Sallieri section; and C. Mrs. Alfred Fowler.

Monsieur MERTENS, Ghent, showed a selection of hybrid Odontoglossums, including O. Vuylsteker, O. amabile, and home-raised O. Wilckeanum. Also a white Cattleya Trianæi, and a coloured variety resembling Backhouseana.

Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), showed the rich lily-coloured Lælia anceps Schroderæ Theodora in splendid condition, and the new and handsome C. Bellerophon (Mrs. Tautz × Calypso), a very dark-coloured variety, the petals and lip being yellow, tinged with dark mahogany red, the dorsal sepal heavily blotched with chocolate purple, the spots changing to rose towards the broad white margin. Also C. Moonbeam (see Awards).

J. GURNEY FOWLER, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), showed Cypripedium insigne Arnoldii, a distinct form, with greenish-yellow flowers, having a clear white upper third to the dorsal sepal, the blotching usually seen in C. insigne being indicated by raised green spots.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, showed two forms of their Cypripedium Countess of Carnarvon (villosum giganteum × Euryades), the one having large purple spots on its dorsal sepal, and the other smaller spots on a purplish ground, the upper part in each case being white.

Messrs. SANDER & SONS, St. Albans, showed a grandly-blotched Odontoglossum crispum, home-raised. The flower was of fine shape, broad in all the segments, white tinged with rose, the greater part of the sepals and petals being covered with rose-purple blotches; crest orange colour.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cypripedium Moonbeam (Thompsoni × Sallieri Hyeanum), from Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt (gr. Mr. H. G. Alexander).—A grand flower in size and form, realising the florist's idea of perfection. In colour it is nearest to a fine form of C. aureum. The large dorsal sepal is pure white, with a yellowish-green base, a broad purple band extending up the middle, with short, rose-coloured, feathered lines on each side from the base. Petals and lip yellow, with a slight green tint, and suffused with purple.

AWARDS OF MERIT.

Odontioda Craveniana (Cochlioda Noezliana × Odontoglossum cordatum), from Messrs. CHARLESWORTH & Co., Heaton, Bradford.—A very fine cross, and a good companion to the scarlet Odontioda Bradshawiæ, for which Messrs. CHARLESWORTH received a First-Class Certificate in January, 1907. The new cross scarcely shows so much of O. cordatum as might be expected, although evidence of it is given in the distinctly-keeled sepals, in the faintest suggestion of mottling in the red of the basal half of the petals, and in the base of the lip; the sepals and petals are red, with a slight golden line. Lip in form much like that of O. Pescatorei. The crest of the lip is yellow, the blade blotched with salmon-red, through which the cream-white ground colour shows in front.

Cypripedium Dædalus Cravenianum (insigne Harefield Hall × nitens magnificum), from J. H. CRAVEN, Esq., J.P., Beeches, Keighley, Yorks. A fine large flower, with a resemblance to C. insigne Harefield Hall, but with the dorsal sepal more flat, and bearing more and smaller spots than that variety.

Fruit and Vegetable Committee.

Present: George Bunyard, Esq. (chairman), and Messrs. Jos. Cheal, Edwin Beckett, Alex. Dean, H. Parr, A. R. Allan, James Vert, Jos. Davies, Geo. Reynolds, J. Willard, Charles Foster, and Owen Thomas.

Messrs. J. VEITCH & SONS, Chelsea, exhibited a collection of Apples and Pears, numbering over 160 dishes, and it was one of the best we have observed at any meeting. Of the finer varieties, mention should be made of the following:—Cox's Orange Pippin, Cornish Aromatic, Paroquet (of a very high colour), Small's Admirable, Winter Peach, Royal Late Cooking, Dumelow's Seedling, Baumann's Red Reinette, Golden Spire, Cellini, Beauty of Stoke, Lady Lennox, Duke of Devonshire, Hormead's Pearmain, Reinette du Canada, Winter Quarrenden, Beauty of Kent, Ribston Pippin, Margil, Schoolmaster, Peasgood's Nonsuch, Egremont Russet (one of the best varieties), Belle Pontoise, Cobham, Lord Hindlip, Chelmsford Wonder, Prince Edward, Tyler's Kernel (unusually well developed for this variety), Blenheim Pippin, Sandringham, &c. The finer Pears were Bellissime d'Hiver, Bergamotte d'Esperen, Beurré Baltet Pere, Olivier de Serres, Beurré Easter, Beurre de Jonghe, Marie Benoist, and Nouvelle Fulvie.

SIR EDMUND G. LODER, Bart., Leonardslee, Sussex (gr. Mr. W. A. Cook), exhibited a fine collection of Apples and Pears, the former from orchard trees of considerable age, and the large size and clear skin of the majority of the fruits

indicated the good cultivation bestowed on the trees. The finer Apples were Mère de Ménage, Dr. Harvey, Traveller, Yorkshire Greening, Bismarck, Lane's Prince Albert, Deux Ans, Ribston Pippin, and Court-Pendû-Plat (very large for this variety). The finer Pears observed were Duchesse de Bordeaux, Passe Crassane, Le Lectier, Duchesse de Nemours, Chaumontelle, Olivier de Serres, Marie Benoist, Beurré Baltet Père, Josephine de Malines, Beurré de Naghan, Huyshe's Victoria, and Easter Beurre, mostly, therefore, consisting of varieties long known in our gardens. (Silver Banksian Medal.)

AWARD OF MERIT.

Potato "Dobbie's Favourite." — From the Society's gardens, Wisley, came five varieties of Potatos, samples being supplied uncooked and cooked. The latter operation was carried out in the tubers' coats. These varieties had been selected by the Fruit and Vegetable Committee when they inspected the Potato trial at Wisley in the autumn, some tubers having been cooked previously. A First-Class Certificate was now unanimously awarded to Dobbie's Favourite, a white, flattish tuber, and a very heavy cropper. This had been previously granted an Award of Merit. Now, having been kept longer, the tubers, when cooked, were so superior in flavour and texture that the unusual award of a First-Class Certificate was readily accorded. It is a late mid-season variety. An excellent Potato was Forester, but it did not secure an award; neither did Dreadnought or Leonardslee Favourite, all three white round varieties; or the red-skinned kidney Cardinal, though all four were heavy croppers. Dobbie's Favourite was one of the most delicious Potatos we have tasted.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending December 28, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The *weather* was somewhat rainy in most parts of the Kingdom during the early days of the week, but subsequently became drier, although with a generally overcast sky. Showers of sleet and snow, however, occurred in most districts, and some heavy falls of rain on the southern and south-western coasts of Ireland and at Scilly. The snow was generally very slight, but some places both in the north-east of England and in the extreme south-west experienced considerable falls. During the latter half of the week the atmosphere was unusually dry.

The *temperature* remained considerably above the average until Tuesday or Wednesday, but afterwards fell quickly and became low, with a very small diurnal range. The mean for the week was above the average in all parts of the Eastern Section except the Midland Counties, and below it elsewhere. The greatest divergence from the normal was + 1·5° in England S. The highest of the maxima occurred on the 22nd at nearly all stations, and ranged from 54° in England E. and S., and the English Channel, to 47° in Scotland N. During the latter part of the week the maxima over a large part of Great Britain were only a little above 32°. The lowest of the minima were recorded on somewhat variable dates, but generally on the 28th in the south and west of England, and on the 23rd or 24th elsewhere. The readings ranged from 24° in England N.W., and 25° in England N.E., to 30° in England S. and Scotland W., and to 32° in the English Channel. The lowest grass readings reported were 15° at Crathes, 20° at Balmoral, and 21° at Hull and Dublin.

The *mean temperature of the sea.*—Generally the water was only slightly colder than during the preceding week, but at Eastbourne there was a decrease of 4°. The actual values ranged from nearly 50° at Plymouth and Salcombe to 40·8° at Cromarty.

The *rainfall* was less than the average except in Ireland S. and the English Channel, the deficit being large in nearly all districts.

The *bright sunshine* was equal to the average in Scotland E., and exceeded it in Scotland N. and England N.W. In all other localities it was less than the normal. The percentage of the possible duration ranged from 20 in England N.W. and 17 in Ireland S. to 4 in the Midland Counties. At Birmingham the week was quite sunless.

THE WEATHER IN WEST HERTS.

Week ending December 25.

A remarkably warm and gloomy week. On each of the first four days of the past week the highest temperature in the thermometer screen rose to, or exceeded, 51°, and on the warmest of those days reached 54°. These are very high readings for a winter month. The first two nights also proved unusually warm for the time of year, the lowest readings indicated by the exposed thermometer being respectively 45° and 42°. On the two coldest nights of the week the same thermometer showed only 2° of frost. The ground has become warm again, the reading at 2 feet deep being now 2°, and at 1 foot deep 4°, warmer than is seasonable. Rain fell on five days, but to the total depth of less than half an inch. On the 22nd light rain began to fall at 8 p.m., and continued without intermission until 1 p.m. on the following day, or for 17 hours. Previous to this fall the percolation had almost ceased, but it is now coming quite freely again through both gauges. The sun shone on an average for 25 minutes a day, or for only about a third of its usual duration at this period of the year. Light airs and calms prevailed during the week, and on one day the mean velocity for the 24 hours amounted to less than a mile an hour. The average amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 2 per cent. *E. M., Berkhamsted, December 25, 1907.*

Week ending January 1.

The most sunless week for four years.—During the past week the highest readings in the thermometer screen have ranged between 37° and 32°, or from 5° to 10° below the average for the end of December. The nights also proved rather cold, but on no night did the exposed thermometer indicate more than 8° of frost. At 2 feet deep the ground is at the present time 1° colder, and at 1 foot deep 2° colder than is seasonable. Snow fell on two days of the week, but at no time was the ground completely covered by it. No measurable quantity of rainwater has now come through either of the percolation gauges for three days. The sun shone on an average for only two minutes a day, or for about 1¼ hour a day short of a seasonable duration, making this the most sunless week recorded here since December, 1903, or for four years. On five days no sunshine at all was recorded. The wind proved, as a rule, rather high, but in no hour did the mean velocity exceed 13 miles. Throughout the last eight days the direction of the wind has been exclusively from some easterly point of the compass. The average amount of moisture in the air at 3 o'clock in the afternoon was 3 per cent. less than a seasonable quantity for that hour. *E. M., Berkhamsted, January 1, 1908.*

Obituary.

E. WARD.—I have to announce the death of Mr. E. Ward, gardener at Longford Hall, Stretford, near Manchester. Deceased was a very clever gardener, and was well known as an excellent cultivator of all choice fruits, especially Pines, Peaches, Grapes, and Melons. He was the only gardener that I am personally acquainted with who could completely cure "Silver Leaf." This he did whilst I was fruit foreman under him, the tree being Royal George Peach, in a late house. The plant, hardy fruit, vegetable, and other departments of the extensive garden at Longford all received great care and attention at the hands of deceased. He endeared himself to the hearts of all young gardeners, for he was one of the best of men. The onerous nature of his duties, together with a naturally modest and retiring disposition, prevented him from looming large in the eyes of the gardening world. *Harry Johns, Birchley Park Gardens, Biddenden, Kent, December 21, 1907.*

GEORGE BATTERS.—The death of Mr. George Batters occurred on Christmas Day at Birkfield Lodge Gardens, near Ipswich, Suffolk. Deceased, who was 43 years of age, was the second son of Mr. Batters, gardener at Gillingham Hall, Norfolk, and had held the situation of gardener to Dr. and Mrs. Bartlett for nearly 15 years.

ENQUIRIES AND REPLIES.

CINERARIAS AND CALCEOLARIAS.—Can any reader furnish me, through the medium of the *Gardeners' Chronicle*, the sizes of the best specimens of Cinerarias and Calceolarias staged in the old country. Here at Corry during the past season we have grown some very fine specimens, and we are anxious to see how they compare with those grown at home. *Cinerarias*—30 specimens in 10-inch pots, flowers 3 inches to 4 inches across; heads of bloom 2 feet 9 inches to 3 feet across; good colours; splendid foliage. *Calceolarias*—30 specimens in 9-inch pots; heads of bloom 2 feet 9 inches to 3 feet across, 8 feet to 9 feet in circumference; splendid markings and colours; Dalkeith Park strain, one plant has nearly 1,000 blooms. My employer, L. C. Mackinnon, Esq., is a subscriber to the *Gardeners' Chronicle*, and he wished me to write you about this matter. Your journal has always a welcome here, and we are looking forward in anticipation to future numbers. *H. B. Downer, Gardener to L. C. Mackinnon, Esq., Corry, Toorak, Melbourne, Victoria, Australia.*

———The cuttings from the Australian papers, and the letter from Mr. Downer, are most interesting to an old florist. I have cultivated both these showy greenhouse plants, and have seen examples of them exhibited in Scotland and London since 1854; but I do not remember to have seen anywhere larger specimens than those grown at the Antipodes. The old system was to grow the Cineraria into very large specimens from propagated plants, three in a 10- or 11-inch flower-pot. This system could not be defended as a method of culture of specimen plants. Large specimens, or a number of specimens in large pots are seldom seen now, either exhibited in public or in private gardens. Some 20 or 25 years ago prizes were awarded for Cinerarias at the April exhibitions of the Royal Botanic Society in Regent's Park. I was frequently an exhibitor in those days and won prizes, but never had any plants so large as those grown by Mr. Downer. Calceolarias are generally at their best in May, but in the case of these, as well as in that of Cinerarias, quality of bloom has been the point aimed at rather than size of plant. On this point there is probably a difference of opinion. The colour of the Australian Cineraria blooms is said to be a deep blue. In any ordinary collection in England there would be some with deep blue flowers, some white with blue margins, others pure white, crimson, purple, white with crimson margins, &c. Some have flowers large enough to cover a crown piece and perfectly circular in form. The strains of seed are of such excellent quality that few people care to propagate their Cinerarias from offsets or division. Gardeners have also come to the conclusion that very large specimens are not so useful for decorative purposes as smaller plants which can be conveniently arranged with other specimens in the greenhouse or conservatory. Evidently the Calceolaria, like the Cineraria, is not as yet well known in Australia. We are informed that "Several of the specimens puzzled expert judges, inasmuch as the blooms resembled something akin to a Snapdragon." The Snapdragon (Antirrhinum) does not resemble a Calceolaria, and the further the form of the blooms is removed from an Antirrhinum the better for the Calceolaria. The one has long shaped flowers placed on a tall stem, whereas the corolla of the Calceolaria has a rounded sac or pouch, and the flowers are produced in clusters. If we refer to the coloured illustrations of the Calceolaria published 70 or 80 years ago, the pouch was considerably elongated, but the art of the florist has brought the corolla into quite a rounded form, and, if possible, a greater advance has been made in improving the colour of the flowers. They are mostly deep yellow, more or less densely spotted with the richest colours, crimsons of various tints being predominant. Calceolarias can be propagated from cuttings or by dividing the old plants, but both processes are unsatisfactory, as seedlings of both are easily raised, and these make better plants at a tithe of the trouble. *Culture.*—A few remarks on culture may be useful. The same compost is suitable for each, and it ought to be rather rich, but not too rich; an over-rich compost causes the plants to die off suddenly; sometimes the branches, but at other times the entire plant will die off. The Calceolaria is more liable to suffer injury in this way than the Cineraria: over-growth is altogether bad, it produces large, flabby leaves, but not a high-class quality of bloom. The seed of the Calceolaria is of the smallest size, and a person not having any knowledge of it should open the seedsmen's packet with great care; before doing so the seed pot or pan should be made ready to receive the seed. Sow them on a quite level surface, and just cover them with very fine soil; place a square of glass over the top of the seed pan to retain moisture. The seed may be sown in June or July, and it will germinate freely in a frame or greenhouse; the soil should be moderately moist, and shaded from the sun. The Cineraria requires similar treatment. The seedlings should be pricked out as soon as they can be easily handled, and be re-potted again in good time, as the plants have to make the best part of their growth by the end of the year. The best compost is one made up of four parts good fibrous loam, one part decayed leafmould, and one part well-rotted stable manure. Under good management the plants of both species will be vigorous enough to need 8-inch pots as their final shift. The worst enemy of both plants is greenfly, but it can be destroyed with the vaporising compounds. This troublesome pest will certainly put in an appearance, therefore keep a watchful eye on the plants, and fumigate immediately any fly is discovered. Calceolarias will succeed in a cooler atmosphere than Cinerarias in winter, as they are not so easily injured by frost. *J. Douglas.*

Answers to Correspondents

A SIEVE OF FRUITS AND VEGETABLES: *A. M.* A sieve is not a recognised measure of capacity; it may be described as a slightly less quantity than a bushel. A sieve of Brussels Sprouts weighs from 36 lbs. to 40 lbs. There are 45 lbs. of Apples in a market sieve and 56 lbs. of Plums.

CARNATION CULTURE: *F. C. B.* The treatment of winter-flowering Souvenir de la Malmaison and other Carnations has been fully described during the past season in our weekly Calendar of work, under the heading of "Plants under Glass." We will reply briefly to your questions. The atmospheric temperature at present should range between 45° and 52° at night allowing a rise of from 5° to 10° during the day, this range being allowed to meet the varying climatic conditions out of doors. During severe weather the lower figure will be the correct one, and in mild weather the higher reading will be safe, but a certain amount of ventilation should be employed whenever the conditions are favourable. This will suit all Carnations. We cannot recommend any particular chemical manure as being better than all other proprietary manures Do not apply any manure of this kind to plants which have not filled the pots with roots. Diseases are often the result of errors in cultivation.

CORRECTION: On p. 451 of the last issue in the article on Quinces, the variety Rea's Monarch should have read Rea's Mammoth.

CYCLAMEN NOT FLOWERING: *F. C. B* The fact that your Cyclamens are healthy one-year-old plants, full of flower buds and yet failing to develop their blooms, points to them having suffered a severe check at a late period of their growth. If the roots are in a healthy condition a little artificial manure, applied strictly in accordance with the directions given by the manufacturers, would be better for the plants than liquid farmyard manure, which is often of an unknown strength, and in the hands of an inexperienced person might be very harmful.

GRAPE VINE THAT HAS GOT INTO A GRAVELLED PATH: *J. Wallace.* It would be advisable to replant the vine, after making a new border, which should extend across the path and a short space beyond it. The area occupied under the present path might be covered with an iron grating resting on brick walls on either side so as to admit the rain and render applications of water possible In the course of time, when the roots have extended beyond the path, the grating might be dispensed with and gravel substituted.

HINTS FOR SCHOOL GARDENS: *S. F., P. H. L. and Others.* Copies of this pamphlet can be obtained from Messrs Dulau & Co., Soho Square, London, or from The West India Committee, Seething Lane, E.C.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: *E. C. C. D* Pernettya mucronata — *J. H. B.* Selenipedium caudatum, often called Cypripedium caudatum; and Selaginella Wildenovii.—*R. A.* 1, Oncidium triquetrum, 2, Brassia maculata; 3, Ionopsis utricularioides.

INSECTS: *H. R., Welbeck* The specimens you enclosed were so rubbed that it is difficult to say to what species they belong. They are probably specimens of the Winter Moth (Cheimatobia brumata) whose caterpillars feed on most trees, and at times cause great injury to the foliage. The female moths are practically wingless and unable to fly, they have to crawl up the stems of the trees in order to lay their eggs near the buds The presence of the winged moths on the bark of the trunks was due to their being in search of the females who would be leaving their chrysalides, which are formed in the ground about this time of year, say, from the beginning of October to the end of December, or sometimes even in January. "Grease-banding" as used for fruit trees is the best remedy.

ROSE GARDEN: *C. W. B.* If you find that the water collects in your clayey soil, then by all means drain it, but, on the contrary, if the shingle subsoil acts as a natural drainage, then it will not be necessary to make any artificial drainage. We are disposed to think this is the case, but you must carefully consider the matter, and act according to your discretion. If you have to make a drain, be careful to provide it with a good fall, and the pipes should be placed at least 3 feet 6 inches deep. It is not necessary that pipes should be placed under each bed. Allow a space of 18 feet from drain to drain; connect them to one main drain along the lowest portion of the ground, and provide a good outlet for the water. Large pieces of chalk may be used round about the pipes, as these will allow the water to percolate freely, and thus drain the ground effectively. Chalk in this form may also be used with advantage at the bottom of the beds below the layer of clay which you have placed there. When you have provided means for the escape of the superabundant moisture, expose the clay to atmospheric influences in order to make it porous and friable; for this purpose also a portion of the clay may be burnt. The additions which may be made to improve the staple soil are already at hand; they include mortar-rubble, wood-ashes, leaf-mould, and well-decayed stable manure. The staple soil for Tea Roses should be of a lighter nature than that required for Hybrid Perpetuals, but it must be borne in mind that it is possible to have the soil too light, and that most varieties of Roses thrive best in a strong soil. The beds should be made some little time previous to planting, in order to allow the soil to settle.

SECKLE PEAR: *Saxon.* This variety of the Pear is not at all rare in gardens in this country, and in the warmer parts it fruits well on low standard and bush trees worked on the Quince stock, or when placed on a west or east wall on the Pear stock. In Scotland and the north of England it is always advisable to plant the Seckle, a tender Pear, on south, east, and west walls The season during which it is at its best would thereby be lengthened by several weeks. If worked on the Quince stock it is advisable to first graft Beurré d'Amanlis, Sucré Vert or Beurré Clargeau on to the stock, so as to obtain a good union and vigorous growth, the next year budding the intermediate stock with the Seckle.

SEED AND SOIL INOCULATION: *Fred W Jeffery, J. H. B., and Others.* You may procure a pamphlet on "Seed and Soil Inoculation," by W. B Bottomley, M.A., Ph.D. Price 1s. Published by *Country Life*, Tavistock Street, London.

VALUATION OF TREES: *J. L.* In making a valuation of the damage resulting from the compulsory lifting and replanting of fruit trees, several matters must be taken into consideration. First, there is the age of the trees, which has a marked effect on the results; young trees two or three years old might be lifted with comparatively little loss, whereas an old or established tree would suffer to a much greater extent. Secondly, the condition as regards health and productiveness prior to the removal must receive due attention For example, a healthy, vigorous tree might be making an excess of growth and be consequently unfruitful; the process of lifting might greatly improve such a tree from a fruit-bearing point of view. On the contrary, examples in full crop-producing condition would be more or less checked, with a resulting decrease of fruits until the trees had recovered; some, indeed, if weakened by heavy crops or defective in any respect, might be seriously damaged or even lost altogether. Much would also depend upon the time selected for the work and the manner in which it was performed. In the autumn and early winter the risk would be reduced to the minimum, especially if the lifting and replanting were carried out in an efficient manner, to the satisfaction of the tenant. Assuming, however, that the 50 trees were in a productive state, and that the work was performed in a thorough manner at a suitable time, it would be fair to realise the damage at the loss of one average crop based on the crops of several years at the average prices prevailing in the district. If the trees are young and have not borne fruit, but are approaching a crop-bearing condition, the estimate must be founded upon the degree of productiveness or the special nature of the variety; thus, with free and early-bearing Apples like Stirling Castle, Potts' Seedling, and Lord Grosvenor, a first general crop might vary in value from 1s. to 2s. per tree, while that of a Cox's Orange Pippin may even exceed the latter amount. As regards the Rhubarb and Raspberries, if the plants are young the loss would be small, but if established and productive, all the conditions being favourable, the valuation for damage could be based on the loss of half the ordinary value of the crop in the season after removal.

WET CLAYEY GARDEN SOIL: *R. S.* There are seven kinds of clays in the British Isles, each of which is differently constituted, there being, however, present in them silica and alumina to a large amount, more especially in pottery clay, fuller's earth, fire clay, Broseley red tile clay, and a few others; and there are much less of such substances as lime, magnesia, potash, iron protoxide, &c., and a variable quantity of water. You have not informed us which kind of clay constitutes the subsoil of your garden, and we can only give an answer that is applicable to clays in general. The soil evidently is in need of draining with water pipes or rubble, preferably the latter, the drains being thrown out to a depth of 4 feet, and 24 feet apart. That work being carried out and a free outlet supplied for the main drain, the land will gradually become freed of the abundant water. It will be advisable to find the water level in the winter months, and the drains should be placed just below this point. It may be advisable also to drain some of the land surrounding the garden, otherwise the inflow of water from this land may tend to keep the soil wetter than would be desirable. Not much of the fresh subsoil, if any, should be brought to the surface in trenching, but it may be dug or loosened with a pick or digging fork and left at the bottom of the trenches, and be afforded a thick layer of strawy litter, and applications of half-decayed contents of hotbeds, rough vegetable refuse, &c. The surface soil may be simply dug the depth of a spade and afforded lime, crushed bones, and ordinary decayed manure. Sand and fine coal ashes would also tend to make the soil lighter and porous, and as a consequence warmer. As land drained naturally or by the hand of man parts with several of its more readily diffusible elements, such as lime, sulphuric acid, and hydrochloric acid, it is an essential point for the gardener and farmer to supply these elements to the soil in small annual dressings. The other constituents of good soil, such as ammonia, potash, and phosphoric acids, are usually retained, only very small quantities of them being found in drainage water.

THE
Gardeners' Chronicle

No. 1,098.—SATURDAY, January 11, 1908.

CONTENTS.

ILLUSTRATIONS.

ADDINGTON MANOR.

ADDINGTON Manor, the seat of Lord Addington, is pleasantly situated in the midst of well-wooded and rich pasture land, about five miles from the ancient town of Buckingham. The planting of the park and pleasure grounds was carried out some 50 years ago by the present gardener, who has seen his work slowly developing as the decades have rolled by, and he still lives to enjoy the partial fruition of his labours, knowing full well that a century or two hence the trees that he planted will by that time have attained to a greater perfection of beauty than they even now possess. The selection of the numerous species, both exotic and indigenous, and their arrangement with respect to position, proportions, and colour, for every season of the year, afford a testimony to his prescience, skill, and taste.

It must not be gathered from the foregoing remarks that the park is entirely devoid of large timber. The reverse is really the case. For though the greater number of the trees are but of 50 years' growth, when the estate was laid out advantage was taken of existing trees in the hedges that divided the meadows and those growing in the hedge-rows on either side of the original highway, which was diverted for the convenience of the estate. It is exceedingly interesting to see how skilfully this older timber has been woven in with the rest to enhance the general effect. A feature which adds to the picturesqueness of one portion of the park, is the pretty and ancient Early English church. The churchyard is separated from the park by a slight fence which is invisible at a short distance away. Just inside the park, near this spot, is an interesting relic in the form of the old stocks, which, though superannuated and out of repair, are a silent monition to the idle, disorderly, and drunken.

At the principal entrance to the park is a one-storeyed Gothic lodge. The avenue is formed by well-grown trees of Spanish Chestnut. There is also a fine avenue of sturdy Elms, planted some 45 years ago, the trees are remarkably even in height and symmetry.

The park is of large extent, and the natural conformation of the ground lends itself to effective landscape gardening, of which advantage has been taken, so that, as one wanders among the trees, unexpected glades, open spaces and vistas are frequently lighted upon. In addition to the trees usually seen in English parks, *e.g.*, the common Oak, Elm, Beech, Ash, Chestnut, Lime, &c., there are many of the rarer and more beautiful of these species, as well as of exotic trees that have become naturalised in this country, as Quercus sempervirens, Q. rubra, Acer vars., Liquidamber, handsome Hollies, both green and variegated species, and many others too numerous to mention. The collection is especially rich in examples of the Coniferæ, and it was interesting to note the growth each specimen has made since it was planted. The gardener has kept a record of the year in which each tree or group of trees was planted, thus enabling a comparison to be made with ease and accuracy. Of Cedars, Cedrus Libani showed excellent growth, and its glaucous foliage betokened perfect health. The same may be said of C. Deodara (these trees were obtained from Stowe House, and planted just 50 years ago). My attention was drawn to a specimen of Pinus Laricio planted in 1872, therefore 35 years old, which was 65 feet high, 5 feet 6 inches in circumference 3 feet from the ground—"a good stick," as the gardener pithily observed. Sequoia gigantea has also developed well: one specimen (planted in 1862) measured—height 80 feet, circumference 4 feet from ground 18 feet, covering 40 feet of ground. Among many others may be mentioned Cupressus Lawsoniana, C. Macnabiana, Abies orientalis (well clothed), A. Douglasii, Picea Nordmanniana, P. nobilis, Pinus austriaca, Thuya Lobbii, Thuyopsis dolabrata, T. borealis aurifera, Cupressus viridis, Cryptomeria japonica, and Taxodium distichum sempervirens. Daffodils, Pheasant's-eye Narcissus, and Colchicums abound in the grass in their season, while the comparatively rare Lady's Slipper Orchid may also be found here.

The conservatory is a handsome structure, admirably adapted for the purpose for which it was built. It is some 22 yards long by 13 yards wide. The end wall is clothed with a luxuriant growth of Heliotrope, the presence of which was quickly detected by its characteristic perfume. Of the larger subjects may be mentioned two fine specimens of Camellia, viz., C. Sasanqua alba plena and C. japonica rosea, the foliage of which showed that the trees were in perfect health, and the already swelling flower-buds indicated a prospective wealth of floral beauty. There is also a well-proportioned Eucalyptus, the bluish tinge of its luxuriant foliage, as it faintly exhaled its unmistakable odour, showing that it appreciated the conditions in which it was placed. Of numerous climbing subjects may be mentioned the common but always beautiful Cobæa scandens, which rioted at will; the delicate Maurandia scandens, twining round supporting wires, with its Gloxinia-like flowers, made a pleasing decorative feature; while a pink-flowered Tecoma, rambling where it could find support, arrested the attention. Among the plants meriting notice may be mentioned some beautifully-marked and well-developed specimens of Coleus and a good example of Fuchsia procumbens. There were also good plants of Begonias, Caladiums, Hoya carnosa, Hibiscus vars., Funkias, Salvia splendens, Panicums, Fuchsias, Sedums.

The mansion is an imposing structure of red brick, with stone embellishments, and, standing as it does on high ground, forms an important feature of the landscape. It is built on the model of an old French château, and its chimneys, dormers, and decorations are fine examples of the builder's art. Around the central tower runs the legend, "Except the Lord build the house, they labour in vain that build it." On the wall facing south were Wistarias and Magnolias, one of the latter carrying, even in the last week of September, a number of handsome pungent-scented flowers.

In front of the house and on one side is an extensive lawn. Formal bedding has been almost entirely superseded, and masses of colour has been relied upon for decorative effect. Dahlias, Gladioli, Asters, Pelargoniums, Montbretias, Nicotiana Sanderæ, &c., are used with excellent results. Easy access to the various levels of the lawn is afforded by means of small flights of steps, on either side of the head of which stand in some cases a well-trimmed Cupressus; in others, a vase containing suitable flowers. On the lawn also are classic vases, as well as some exquisite statuary of children. From this point, a scene of peaceful beauty opens upon the view. On the late September afternoon, when I saw it, not a cloud stained the azure of the sky, not a breath of wind stirred the foliage of a tree. To the right lay the ancient church of Addington, while across the lawn the lovely shades of green on the trees of the park were illumined by the afternoon sun. Not yet had frost or wet or gales of wind done havoc, though here and there were visible the flame of the Liquidamber and the golden hue of the Maple. The eyes wandered over a broad landscape of sylvan beauty, in which nestle pretty Buckinghamshire homesteads and hamlets, till the horizon is bounded by the hills of Quainton and Brill, forming spurs of the far-famed Chiltern range.

One of the most interesting features of this estate is the herbaceous garden. It is of large extent, and may be roughly described as in the shape of an egg-timer, though the garden is not proportionately so narrow at the waist. In the centre is a well-kept lawn, with a border varying in width all around it. The whole is enclosed with a magnificent hedge, 9 feet high and 4 feet thick, formed of Thuya Lobbii. The hedge is clipped twice a year, and the severity of its line is relieved by "flying buttresses" of the same Conifer. Nearly the whole year through the garden affords pleasure to the lover of flowers. Being sheltered, the earliest of spring-harbingers soon appear. Then the lawn is a sheet of Daffodils and Pheasant-eye Narcissus. Later the borders are brilliant with summer-flowering perennials; while in autumn they are still gay with Chrysanthemums, Aquilegias, Roses, Dahlias, Sedums, Phloxes, Helianthus, Malope,

Marigolds, Œnotheras, Bocconias, Epimediums, Acanthus, Achilleas, &c.

The kitchen garden is entered through a handsome wrought iron gate of Italian workmanship. On the walls that encircle this garden are well-grown Pear trees, which, at the time of my visit, were bearing remarkably heavy crops. They consisted of the following varieties:—Williams' Bon Chrétien, Marie Louise d'Uccle, Bergamot Esperen, Louise Bonne of Jersey, Pitmaston Duchess, Souvenir du Comice, and Beurre Diel (Beurré Magnifique). A good crop of Plums had been gathered, chiefly of the varieties Victoria, Orleans, Transparent Gage, Green Gage, Monarch, and Grand Duke. Apples are grown chiefly in bush form. Unfortunately, the yield last autumn was not a prolific one. The varieties Ribston Pippin, Wellington, Cox's Orange Pippin, Manx Codlin, and Ecklinville Seedling have given the best results. The small bush-fruit trees looked healthy, and had yielded well in their season. There was a profusion of winter-greens of the usual types showing good culture. A magnificent crop of Onions was drying in the autumn sun. Bordering the vegetable beds were planted a variety of perennials for cutting for decorations, such as Sweet Peas, Valerian vars., Mignonette, Senecio clivorum, Pentstemons, Nicotiana affinis, Salvia, Buphthalmum, Mrs. Simkins Pink, and others.

There is a lake on the estate some two acres in extent which, though teeming with fish and often crowded with wild water-fowl and pleasantly situated, is disappointing from a floricultural point of view. One would have liked to see there some of the beautiful water-plants of which such a wide selection can now be made. I must not forget to mention a pergola covered by Nasturtiums, Clematis Jackmanii, Honeysuckles, and rambling Roses such as the popular varieties Gloire de Dijon and Reine Henriette, which, in spite of the lateness of the season, were carrying good flowers.

The stove house is a commodious structure. The end wall is clothed with luxuriant growth of Ficus radicans, and rambling riotously were plants of the beautiful Allamanda cathartica in full flower. There were also a great number of plants of Begonia Gloire de Lorraine developing well for winter decoration, and a small but choice collection of Orchids.

In the fruit houses were some well-developed Peach trees, which I was told had borne excellent crops. Of Grapes, the varieties principally grown were Black Hamburgh, Muscat of Alexandria, and Black Alicante. The Grapes did not look so well as they might have done, owing to some neglect through the illness of the gardener earlier in the season. Fair crops of Tomatos were ripening.

There were also a large number of splendid plants of Chrysanthemums of the best varieties, carrying buds of large size. When the flowers developed they would take no mean position among competitors upon an exhibition board.

The gardens are in the charge of Mr. John Matheson. Though he has reached the age of 83 years, his eyes are not yet dim nor is his natural force abated. He has held the position of gardener for 53 years. That he is proud of the results of his work is but natural, and he is to be congratulated on the appearance of the plant-houses and park, flowers and lawns; but perhaps what causes the aged gardener the greatest pleasure and his heart to beat with honest pride is when he shows the chair presented to him by Lord Addington on the completion of 50 years' service, on the silver mounting of which is inscribed an appreciation of his worth and integrity. In these days of economic changes and industrial warfare it is refreshing to meet with such an instance of the reciprocal esteem of master and servant. *Richard P. Hesketh.*

THE WINTER STORING OF APPLES.

THE collection of Apples staged on December 21 at the Horticultural Hall, by Messrs. Jas. Veitch and Sons [awarded the Society's Gold Medal], was one of the finest ever seen on such a date, and shown, too, as the product of a year far from being a favourable one for Apple production. The fruits were in every case so firm and apparently fresh, they naturally led to enquiry as to the nature of the store in which the fruits had been housed. The store is a large, span-roofed house, and stands quite in the open. In that respect it resembles Messrs. G. Bunyard and Co.'s fruit house in their Allington Nurseries, as also it does in being thatched and coated round the sides with reeds. Originally, Messrs. Veitch's house was coated with heather, as is the fruit house at Wisley, but it was found that this covering harboured birds, and the heather was therefore taken away and Norfolk reeds substituted. The inside of the house is match-boarded. The shelves round the sides are 2½ feet wide, and 1½ feet apart, and are composed of stout wood laths, forming open trellis shelves, the sharp edges of the laths being planed off.

In the centre of the house, which is 13 feet in width, is an exhibition stage 3 feet wide, on which special samples of each variety of Apple are placed for comparison and recognition. At one end is a double door, and ventilation is given by louvre openings above the door and in the farther end. These openings can be effectually closed by movable shutters during hard weather. The floor of the house is, like that of the Allington house, of earth, and is occasionally damped with water to promote a slight humidity—an atmospheric condition of supreme importance in helping to keep the fruits firm. A great error with so many Apple stores lies in having wooden floors, thus promoting excessive dryness, as there can then be no soil exhalations. It is right to have proper ventilation to maintain a pure atmosphere, but a very dry one, such as is absorbent of the juices of the fruit, is by no means desirable.

That such firm examples of Apples as these from Langley or from Maidstone, and other nurseries, can be shown during the winter is, however, due to some other causes besides good storing. Without doubt, the bulk of the samples having been grown on young trees and near the ground, the fruits have been well fed with fruit requirements. They have been allowed to hang on the trees to the latest possible period, and have been fairly near the soil, hence have derived from it some assistance because of the greater humidity of the air than is the atmosphere higher up. These facts serve to show how important in Apple culture it is to maintain a constant supply of young trees.

An interesting experiment in relation to Apple storing at Langley was once told me by Mr. Algrove, the fruit manager. Whilst the centre stage was open lathed, one side stage was close boarded, the other side stage being covered with glass. Six fruits of numerous varieties of Apples were placed on each of these three stages and their keeping qualities severely tested and carefully noted daily. Ultimately the result showed that the fruits on glass, because any moisture engendered on them by sweating passed down to the base of each fruit and settled there, not passing away, promoted early decay. Those on the close boards suffered less, though they did suffer to some extent. Those on the open laths did not suffer at all, and therefore kept much the longest. Whilst it was held that any moisture engendered on these fruits could freely pass away and leave them dry, it is also most probable that on account of the free circulation of air through the open laths, very little if any, moisture settled on the fruits, and there was therefore none to remain on the laths to engender decay.

We may grow Apples well, but if we want to keep them late, we must seek to do so by the best methods. *A. D.*

FIG. 13.—ODONTOGLOSSUM CRISPUM "MEMORIA BATTLE OF WATERLOO," RECENTLY EXHIBITED IN BRUSSELS BY M. JULES HYE DE CROM.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM CRISPUM VARIETY.

THE variety of which we give an illustration (fig. 13) is taken from a flower kindly sent us by Monsieur Jules Hye de Crom, Ghent (gr. Mr. Mertens), who exhibited his specimen with 16 flowers at the meeting of the Sociétés Royales Linnéenne et de Flore de Bruxelles on December 15, 1907, when the plant was accorded a Diplome d'Honneur. Reference to the illustration, which represents the flower in its natural size, will show that it is a very handsome variety. The ground colour is white, slightly tinged in places with rose colour, showing through from the purple shade on the reverse side. The blotching is deep blood-red.

STANHOPEA OCULATA.

OUR illustration at fig. 14 represents a plant of Stanhopea oculata grown by Mr. W. R. Wright, The Gardens, Aldborough Hall, Ilford, the plant when photographed bearing the last two of the six inflorescences which it has borne this season. The species, which was first imported from Mexico, in 1829, flowered in Messrs. Loddiges' nursery in 1831, and has since that time been well known in gardens. The flowers are cream-white, spotted with rose-purple and bear a blackish spot on each side of the basal part of the lip.

CYPRIPEDIUM STANIS

(WILLIAMSIANUM × INSIGNE SANDERÆ).

THIS is a finely-shaped Cypripedium, which has flowered with Eustace F. Clark, Esq., Chamonix, Teignmouth, who names it after his son, Stanislaus. All the parts are broad and well arranged. The dorsal sepal is emerald green, darkest in the veining, the margin white, and bearing a few purple spots at the base. The petals are 1 inch in width, and have a greenish ground colour tinged and veined with purple, and marked with a few small purple spots on the inner parts. The staminode is as broad as the basal part of the lip; its colour is pale yellow veined with green; the broad lip is cream-white tinged with red.

FIG. 14.—A FINE INFLORESCENCE OF STANHOPEA OCULATA.

CYPRIPEDIUM × EUSTACIANUM

(C. SUPERBIENS × ARGUS).

THIS very pretty variety plainly indicates a blending of the features of both the parents, and in point of beauty it excels each of them. The size and graceful outline is of C. superbiens (Veitchii), the effective blotching is derived from C. Argus. The broadly ovate acuminate dorsal sepal is white tinged on the lower half with rose colour, and bearing about two dozen green lines, every alternate one being finer and shorter than the rest. The deflexed petals are two and a half inches long, and over half an inch in width. They are white, with pale green lines at the base, flushed with rose on the outer halves and bearing numerous warted, chocolate-purple blotches, those on the margins being hairy. The large, well-formed labellum is whitish, veined with green, and tinged on the face with rose. It flowered with Eustace F. Clark, Esq., Chamonix, Teignmouth, from seeds sown in January, 1903.

TREES AND SHRUBS.

SPECIES FOR CHALK SOILS.

THE soil here is a thin loose chalk, varying in depth from 6 to 15 inches; underlying this is a few inches of chalky pebbles, and on passing through the pebbles the solid white chalk rock is encountered. The labour necessary to convert such land into profitable garden ground is very great, and the initial work is generally costly. Circumstances sometimes make it imperative to excavate the ground, but in the majority of instances a sufficient depth of soil has been secured by forcing the ground to a higher level.

From the nature of the subsoil, porosity is a marked feature, and as water passes rapidly away the ground renders to half-hardy subjects perfect immunity from the bane of many soils, namely, excessive moisture at the roots in winter.

Under the influence of summer heat and prolonged drought, chalk soils support vegetation better than most other mediums, which is no doubt explained by the presence of rock fragments in considerable quantities. As is proved when moving established specimens, the roots cling to the rocky floor in a most tenacious manner, showing how much the roots appreciate the cool sub-stratum; it is on such soils that considerable difficulty is experienced in re-establishing large specimens.

The general effect upon flowering subjects is an annual growth of short wood, which invariably ripens well, and rarely fails to produce fine crops of well-developed and richly-coloured flowers, and it is further noticeable that the autumn tints of many trees and shrubs are singularly rich and constant at that season.

I have frequently heard comments upon the rich, glossy appearance of the leaves of evergreens; such well-known examples as Holly (Ilex), Choisya ternata, Azara macrophylla, Viburnum Tinus, Ligustrums and Escallonias, and many others, present a very pleasing feature in the winter by the unusual richness of the leaves. This may partly be explained by our proximity to the sea, which lies 12 miles east, but I have never seen Choisya or Azara grow with such vigour elsewhere. From our position, we generally experience late and trying springs, and as these "wolds" are wind-swept for seven or eight months of the year, the provision of adequate shelter is of more than ordinary importance. Fortunately we have Beech, Sycamore, Austrian Pine, and Evergreen Oak available subjects for planting, which not only reach perfect development on the shallowest soil, and furnish the best of shelter, but the timber is often of considerable value. Of undershrubs that succeed in Beech woods, we have had the best results with Euonymus japonica, Aucuba, Ruscus aculeatus, Buxus sempervirens, and Ilex aquifolium.

Evergreens employed in garden decoration, other than those already noted, are Escallonia exoniensis, E. Langleyensis, E. macrantha, and a broad-leaved form of E. macrantha. Garrya elliptica grows and flowers freely in the open, and it is interesting to note a group of Ericaceous shrubs like Arbutus violating a knowledged traditions, and making themselves at home in the chalk. Arbutus Unedo coccinea, rubra, and Menziesii are the forms grown here. Arbutus Unedo coccinea, if only for the bright red bark in winter, should be extensively planted.

Olearias are represented by O. Haastii, O. Gunniana, O. macrodonta, and O. nitida, the latter scarcely as often planted as its merits deserve. The best species and forms of Ulex and Cytisus succeed well, including the Sweet-scented Spartium junceum; these, when employed with the hardiest varieties of Cistus, form a valuable group of plants for converting dry banks or like positions into objects of beauty with the minimum of expenditure and upkeep. Some of the rarer Evergreens have but recently been planted, among the most promising are Daphniphyllum macropodum, Cornus capitata, Desfontainea spinosa, Cotoneaster angustifolia, Osmanthus ilicifolia purpureus, Phillyræa decora; those having the protection of a wall are Senecio elæagnifolius, Carpentaria californica, Fremontia californica, Cistus ladaniferus, and Jasminum primulinum.

Mention may be made of a colony of Bamboos represented by a dozen sorts, which have been planted about six years; the canes rarely exceed 12 feet in height, the yearly growth being most satisfactory.

Deciduous trees and shrubs which succeed on the chalk include Abutilon vitifolium, Cercis Siliquastrum, Cercidiphyllum japonicum, Dimorphanthus mandshuricus, and the two variegated forms; all the species of Cornus except C. Kousa; Cratægus and Cerasus in many forms, Aronias (Pyrus), Amelanchiers, Berberis (evergreen and deciduous), Ginkgo biloba, Gleditschia triacanthos, Liquidamber, Liriodendron tulipifera, Parrotia persica, Pyrus, Rhus, Robinia, Spiræa, and Syringa.

Among the most promising of new deciduous shrubs are Amelanchier oligocarpa, Cæsalpinia japonica, Davidia involucrata, Prunus spinosa purpurea, Eleutherococcus Simonii, Euonymus nanus, Hamamelis mollis, Syringa Josikæa eximia, this last a delicately-coloured Lilac.

Having remarked upon the leaf tints of many trees in autumn, it remains but to note a few of the most brilliant—Aronia (Pyrus) florifera, coccinea, erythrocarpa, Berberis Thunbergii, Amelanchiers, Cercidiphyllum, Ginkgo, Gleditschia, Parrotia persica, Rhus in variety, Stephenandra flexuosa, and S. Tanakæ, Spiræa prunifolia fl. pl. and S. Thunbergii. In most positions, with special soil free from lime, which gardeners on chalk soil may readily procure at a slight expense, there is nothing to beat the colouring of Oxydendron arboreum, while the ruddy shoots of Leucothoe racemosa are borne by the leaves through the greater part of the winter. *Thomas Smith, Walmsgate Gardens, Louth, Lincs.*

ROMNEYA COULTERI.

THIS exquisite Mexican Poppy is generally recommended for light, sandy or peaty soils, but in the heavy, sticky clay here it does admirably. I planted, in 1906, a small piece of which I had about 1 foot deep, in which I mixed with the

clay soil at planting some sand and leaf-soil. In the first year it gave three flowers, but in 1907 it has grown vigorously and has given a quantity of its silvery-white blossoms (6 inches over), which have been greatly admired. It is fully exposed, and has not been given any protection. The plant is now 4 feet through, and full of shoots. As many of them were October growths, I have now put some ashes round the crown. Do not let those who have a heavy (Rose) soil, therefore, despair of growing Romneya Coulteri. *George Bunyard, Oakwood Lodge, Ide Hill, Sevenoaks.*

NOTICES OF BOOKS.

*"The Minimisings of Maurice."

This is a book specially written for children, and one in which many truths concerning natural history are related in such a manner as is considered to be most interesting to the juvenile mind. It relates the adventures of a boy who, aided by his Fairy Fancy, has the power of "minimising himself" to any size he requires. After reading the opening chapter it seems no longer wonderful that he should be able to wander among the inhabitants of the garden, the field, and the pond, or even speed away on the wings of a butterfly and describe his experiences on such journeys. In this way the narrating of his interviews with the owl, kingfisher, rook, dormouse, squirrel, bee, water-beetle, toad, frog, dead nettle, the aerial roots of the Ivy, "lady" teasel, &c., discloses much accurate information about their habits and uses, and child-readers may be reasonably expected to retain some of these particulars even if they are not led to make further observations themselves or to study more advanced books. There are 36 excellent illustrations which are reproductions of photographs direct from Nature. This work is an attempt to sugar-coat the pill, and may be recommended as one of the very best of its class.

†"The Flower Garden."

Mr. Sanders is already well known as the author of several useful books on gardening, and the present volume forms an excellent addition to its predecessors. It may be thoroughly commended as a reliable guide. The plan of the work is good and business-like. Opening with an account of the various aspects of gardening, the author goes on to deal in detail with the different parts of the subject in separate chapters. This method of treatment will appeal to those who use the book by reason of its convenience.

First come the hardy plants; then the bulbs, Orchids, aquatics, Ferns, &c., are all separately considered and dealt with. The treatment of the various tender outdoor plants, climbers, and the hardy trees and shrubs ends an excellent book, in which the space available is utilised with considerable judgment. The 64 full-page illustrations form an attractive feature of the work, and some of them possess no small artistic merit.

‡"Flowers and Fruit for the Home."

This little book will appeal to those who are interested in the rather gossipy type of garden book. The author manages, however, to convey a fair amount of information in the style of the newspaper article, and the illustrations that accompany the text are well executed.

* By Rev. S. N. Sedgwick, M.A.; published by Elliot Stock.

‡ By T. L. Richmond. T. N. Foulis, Edinburgh and London, 1907.

NOVELTIES OF 1907.

(Concluded from page 3.)

Some of the favourite garden flowers have recently been remarked upon in these columns; the appended list of the most important plants and fruits illustrated in the *Gardeners' Chronicle* during the past year will be a sufficient reminder of the progress made in all branches of horticulture.

Hardy trees and shrubs, both flowering and ornamental, are of special interest, as their culture can be undertaken by all having gardens. In this matter the new introductions from China by Messrs. Jas. Veitch & Sons, through their representative, Mr. Wilson, and which are now beginning to show their real worth and obtain the recognition they deserve, take the place of honour among new plants. Messrs. Jas. Veitch & Sons secured First-Class Certificates for the compact and free-flowering Rhododendron intricatum (first shown as nigro-punctatum), Viburnum rhytidophyllum, and Berberis Wilsonæ. Awards of Merit were obtained for the pretty hybrid raised by them between Primula pulverulenta and P. Cockburniana, and named Unique; Azalea Hexe, a bright red variety; Actinidia chinensis, a good pillar plant; Lonicera Maackii, a hardy cream-white species, which also bloomed with Messrs. Paul & Son, Cheshunt; Cotoneaster applanata, Vitis leeoides, and other pretty species, and among more tender plants Nepenthes Ruby, one of the largest and brightest in colour; Amphicome Emodi, Kalanchoe Dyeri, and Caladium Thomas Tomlinson.

Other hardy flowers which have secured Awards are Iris Aspasia and Melusine, from Mr. F. Herbert Chapman, Rye (who also showed the pretty yellow Freesia Chapmanii); Iris Luna and Freesia Tubergenii Amethyst, of Mr. C. G. Van Tubergen; Iris Caterina and I. Paracina, of Messrs. Barr & Sons, who also have some good new Daffodils; Rhododendron Duke of Cornwall, a fine red variety from Tremough; the fine purple Syringa Josikæa var. eximia, Campanula longistyla, and Arctotis regalis from Sir Trevor Lawrence's gardens; and many other acceptable novelties shown by Messrs. Wallace, Colchester; Kelway & Son, Langport; Carnations by Mr. Jas. Douglas; the very small-leafed Ampelopsis Veitchii Lowii of Messrs. Hugh Low & Co.; and some excellent new Daffodils which have secured recognition by the Narcissus Committee. Among these were the varieties Homespun, Ailsa, and Miss Willmott, all fine flowers.

Stove and Greenhouse Plants.

Novelties in this class have not been shown very numerously in 1907. Among the best of those certificated are Hippeastrum Vulcan and H. Lady Howick, from Major G. L. Holford; H. Mrs. Carl Jay, a fine hybrid of H. reticulatum, from Mrs. C. Jay, Bexley; the dwarf and pretty Crinum amœnum var. Mearsii, from Col. Beddome, and the more showy variety H. J. Elwes, from Mr. Elwes; the fine Agapetes speciosa, from Mr. J. T. Bennett-Poë; and the excellent strain of Streptocarpus, for which Mr. Burkett, of Sunningdale, received an Award of Merit last August.

Ferns which have secured Awards during the past year include Cyrtomium falcatum Rochfordii, with fringed fronds, and Polystichum aculeatum Drueryi, one of the most elegant of hardy Ferns, both of which secured First-Class Certificates; also Nephrolepis exaltata Whitmanii and Davallia brasiliensis (H. B. May), both of which were accorded Awards of Merit.

The Roses, Sweet Peas, Carnations, and Chrysanthemums have all been well represented by the novelties of 1907, which have been duly recorded. The Dahlias, Begonias, and other large classes of florists' flowers have also been strengthened by the specialists in the different classes, and the seedsmen have not failed in furnishing novelties of sterling merit.

The following new and noteworthy plants and fruits have been illustrated in the *Gardeners' Chronicle* in 1907:—

Abies magnifica xanthocarpa, Feb. 23, pp. 114-115.
Acacia caffra, Jan. 12, p. 20.
Acantholimon echinus, May 18, p. 311.
Agapetes speciosa, April 13, p. 237.
Amphicome Emodi, Oct. 19, p. 276.
Anchusa italica, Dropmore variety, Oct. 19, p. 282.
Apple Ard Cairn Russet, March 16, p. 174.
Apple Encore, Jan. 5, p. 2.
Apple High Canons, March 2, p. 133.
Apple Ross Nonpareil, March 23, p. 182.
Arctotis regalis, Sep. 14, p. 204.
Argemone grandiflora, Aug. 10, p. 113.
Asparagus falcatus (flowering), Feb. 2, p. 82.
Aster Norah Peters, Oct. 12, p. 269.
Auricula Miss Berkeley, May 4, p. 286.
Begonia Miss Clibran, Nov. 16, p. 347.
Berberis Wilsonæ, Nov. 30, p. 372.
Bryophyllum calycinum, Supp., June 29.
Bryophyllum crenatum, June 29, p. 419.
Calceolaria Veitch's hybrid, June 29, p. 426.
Campanula longistyla, Sep. 14, p. 191.
Campanula mirabilis, Aug. 24, pp. 144-145.
Campanula punctata, Aug. 3, p. 96.
Campanula trœa, Sep. 14, p. 197.
Carnation Aristocrat, Dec. 21, p. 420.
Caryopteris Mastacanthus, Dec. 14, p. 409.
Chrysanthemum Horace Martin, Oct. 12, p. 267.
Chrysanthemum Miss Hampson, Jan. 5, p. 9.
Chrysanthemum Thyrza Cherry, Jan. 5, p. 9.
Citrus (Orange) Excelsior, Feb. 23, p. 124.
Cladrastis tinctoria, Sep. 7, pp. 186-187.
Cosmos sulphureus, Supp., Aug. 24.
Cordyline Banksii, Supp., Feb. 23.
Cordyline indivisa, Feb. 23, p. 123.
Crinum amœnum var. Mearsii, July 27, p. 62.
Crinum H. J. Elwes, July 20, p. 53.
Cyclamen latifolium, March 30, p. 207.
Diervilla sessilifolia, Dec. 21, pp. 426-427.
Diospyros Kaki and fruits, July 13, pp. 22-23.
Dipelta floribunda, July 6, p. 2.
Dombeya rotundifolia, Jan. 12, p. 21.
Erinacea pungens, May 18, p. 310.
Eryngium proteiflorum, April 20, pp. 248-249.
Eucalyptus ficifolia, Supp., Nov. 30.
Eucryphia cordifolia, Oct. 12, p. 259.
Felicia petiolata, Aug. 3, p. 82.
Ficus cordata, Jan. 19, p. 35.
Gladiolus atroviolaceus, June 15, p. 378.
Gladiolus Peace, Supp., March 30.
Gladiolus primulinus, Oct. 26, p. 291.
Gladiolus The Bride, June 22, p. 398.
Gnidia polystachya, May 11, p. 294.
Heeria elegans, Oct. 26, p. 293.
Hippeastrum Mrs. Carl Jay, June 29, p. 424.
Hippeastrum Queen of Spots, Supp., April 27.
Impatiens oppositifolia, Aug. 10, p. 102.
Itea ilicifolia, Aug. 17, p. 123.
Kale Chou de Russie, April 13, p. 242.
Larix Griffithii, March 2, pp. 130-131.
Lomatia ferruginea, Supp., Sep. 28.
Lonicera Maackii, April 27, p. 265.
Lychnis grandiflora, Sep. 7, p. 189.
Lychnis Haageana var., Oct. 5, p. 243.
Mammillaria rhodantha, crested, Oct. 26, p. 290.
Matricaria Bridal Robe, Aug. 31, p. 165.
Meconopsis racemosa, July 13, p. 31.
Montanoa bipinnatifida, Dec. 14, p. 419.
Moræa iridoides, May 11, p. 297.
Moræa iridioides, Johnson's var., May 11, p. 296.
Musa Basjoo, Feb. 16, p. 101.
Narcissus Homespun, April 13, p. 240.
Narcissus Open Face, April 13, p. 241.
Neviusia alabamensis, Supp., Jan. 19.
Notospartium Carmichaeliæ, Aug. 24, pp. 146-147.
Nymphæa atropurpurea, Supp., Feb. 16.
Olearia nitida, Aug. 3, pp. 94-95.
Pear Beurré de Naghan, Dec. 28, p. 444.
Pear Blickling, Jan. 19, p. 34.
Pelargonium Clorinda, Sep. 28, p. 228.
Phlox subulata lilacina, June 15, p. 383.
Polystichum aculeatum Drueryi, Oct. 19, p. 274.
Plagianthus Lyallii, Supp., May 25.
Plum Peach hybrid, April 20, pp. 256-257.
Primula Palinuri, Jan. 12, pp. 18-19.
Primula pulverulenta, June 15, p. 301.
Primula sikkimensis variety, June 1, p. 350.
Primula The Czar (Sutton's), March 2, p. 143.
Primula Unique, June 15, p. 395.
Rhododendron intricatum, April 27, p. 262.
Rhododendron Purity, July 6, p. 15.
Rhododendron Duke of Cornwall, Supp., June 22.
Rondeletia umbellata, Sep. 28, p. 226.
Romneya trichocalyx, Supp., Dec. 14.
Rosa polyantha Ännchen Müller, Supp., June 1.
Rose Hugo Roller, Aug. 3, p. 92.
Rose Joseph Lowe, July 20, p. 46.
Rose Lady Helen Vincent, July 13, p. 36.
Rose Mme. Plantier, July 6, p. 5.
Rose Mrs. F. W. Flight, Sep. 28, p. 238.
Rose Paradise, June 15, p. 385.
Rose Pride of Waltham, July 6, p. 13.
Rubus bambusarum, Oct. 5, p. 251.
Rudbeckia Heliopsis, Supp., Feb. 2.
Semele androgyna, Oct. 5, p. 251.
Senecio Wilsonianus, Supp., Sep. 14.
Sinningia Hellerii, June 1, p. 342.
Schizanthus, Sutton's varieties, June 8, p. 365.
Stewartia malachodendron, July 13, p. 27.
Streptocarpus, Burkett's strain, Sep. 28, p. 229.
Sweet Pea Countess Spencer, Aug. 10, p. 111.
Sweet Pea, new varieties, Supp., Aug. 10.
Syringa Josikæa eximia, Supp., Oct. 19.
Tchihatchewia isatidea, Nov. 9, pp. 234-235.
Tellima pedata, Jan. 19, p. 35.
Viburnum rhytidophyllum, Sep. 21, p. 220.
Viola gracilis, June 1, p. 358.
Zaluzianskya maritima, Aug. 31, p. 15.

A set of fastigiate trees have been illustrated in these pages during 1907, and form a very useful reference.

NUNEHAM PARK.

(Concluded from page 11.)

THE WATER GARDEN

has been laid out in an artistic manner, and presents many attractive features. It follows a serpentine course, and a clear, trickling rivulet passes gracefully over several miniature falls, each one enhanced in beauty by beautiful blue Gentians and Iris Kæmpferi. Clumps of rock placed beside the water diversify and break up the surroundings; the artist, in order to naturalise his picture, has grouped clumps of Iris anglica and I. stylosa, and Incarvillea variabilis, together with the bright Primula japonica. Near at hand is planted Saxifraga ligulata, Lobelia cardinalis fulgens, Lilium giganteum, Rheum palmatum, Phormium tenax, Echinops humilis, Lysimachia clethroides, &c. Mr. Munday is now busy in forming or converting the dell pond into a charming spot by the formation of a rustic path of stones entwining its way in and about the bank. Already Phormium tenax, Ferula gigantea, and Senecio clivorum are planted, and the beautiful Royal Fern, Osmunda regalis, Cotoneaster frigida, Gunnera manicata, Fuchsia Sieboldii elatior, Bamboos, Trilliums, Ranunculus bilobus, Glyceria spectabilis, &c. A rustic bridge affords approach to these plants across a small stream.

THE ROSE GARDEN

proper contains, as far as my memory serves me, about 600 to 800 plants of all the finest Tea and Hybrid Tea varieties. The outside border is 8 feet wide and planted with Princess de Sagan, and about 100 varieties planted in "3's," a good method of obtaining "blocks" of colour. The rockery, supposed I believe to be the work of "Capability" Brown, is planted with Sedums and Saxifragas in variety. Tiarella cordifolia, Helianthemum diversifolium, Crucianella stylosa, Epimedium sulphureum, Heaths, Dianthus alpinus, and many beautiful Alpines.

THE PERGOLA

is built with brick pillars 14 inches square and 8 feet high, crossed at the top with oak beams; the brick walk below is laid herring-bone fashion on edge. A space of 8 feet is allowed from pillar to pillar, which extends round a water tank 28 feet in diameter. Thirty kinds of Vitis are planted; the species include: Vitis vinifera, V. riparia, V. rupestris, V. rubra, V. Henryana, V. Coignetiæ, V. Labrusca, V. striata, V. Brandti, V. flexuosa, V. amurensis, and V. capriolata. Several varieties of rambling Roses and Clematis help to furnish this most interesting collection.

In one section of the kitchen garden a very substantial fruit enclosure has been erected, covered with small-meshed wire-netting 190 feet by 50. Raspberries, Gooseberries, Plums, and Cherries are its principal occupants. Each and all give promise of excellent crops. Most of the leading kinds of Pears, Apples, Cherries, Apricots, and other fruits have been planted against the walls, and as pyramids round the patches.

THE KITCHEN GARDEN.

The gardener is well aware of the requirements of a well-appointed establishment; crops in various stages are in excellent culture. The vines have mostly been replanted in newly-made borders; one old vine of Black Alicante, occupying two houses, was over 30 yards long. Peaches and Nectarines in some cases are being renewed.

Considerations of space forbid the description of the plants which are grown under glass, and I have therefore confined these remarks to the many attractive features of the open-air parts of the grounds. *W. H. C.*

FIG. 15.—VIEW OF A PORTION OF THE WATER GARDEN AT NUNEHAM PARK.

FORESTRY.

THE LARCH APHIS AND BLISTER.

I THINK some facts have been overlooked in this matter (see pp. 353 and 438). The Larch disease "blister"—begins in two ways. As a rule, judging from many examples, the disease begins in young plantations by attacking the stem mainly and creeping up with the tree's growth until, in the case of badly-affected trees, blisters cloth the stem from top to bottom, killing the tree outright or arresting its growth to such an extent that the tree never gets thicker than a rail. Extensive examples were shown at the Royal Agricultural show, at Islington, in June last. In Wilts, Dorset, and Wales especially, extensive plantations are to be seen like this, but in all of

them are to be seen good trees as well that are quite clean, and others only partially affected. Cases of this kind may, and do, arise, in which the aphis apparently plays no part.

As to the other way in which the disease begins, there seems to be no doubt that it is caused by the Larch aphis. The time, the sudden attack, and distribution of the disease all point to this conclusion. The disease appears, comparatively speaking, suddenly all over the plantation, and such examples may be seen often. One example will suffice. On a favourable position for Larch, on a hillside near Maxwelltown Braes, in Dumfriesshire, a healthy, well-established Larch plantation, free from disease and supposed to be out of danger, was, within the space of two or three years, affected badly all over with blister, as if it had fallen on the trees in a shower. The owner and his agent told me that a few years before, during a dry summer, the plantation suffered from a very bad attack of aphis, and both attributed the disease to that, without having read or heard much on the subject of disease before. This was about six years ago, and I have seen similar examples since. I think, if the theory that the Larch fungus enters at a wound is correct, there is no doubt about the aphis making wounds in millions for the disease to enter, and that seems to be about the logic of the case. *J. Simpson, Studfield.*

The Week's Work.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Peaches and Nectarines.—In many gardens, especially if the earliest maturing varieties are cultivated, there is no necessity to start the trees earlier than the commencement of the year, and if fruits of the best quality are required, it is not advisable to force them sooner. There need be no difficulty about starting at this date trees that have been forced early in the previous season; afford them a steady atmospheric temperature of from 45° to 50° at night, with a rise of about 5° by day, admitting air cautiously in mild, sunny weather, but close the house sufficiently early to cause the temperature to remain for a short space of time at about 60°. Atmospheric moisture should be provided, depending in amount on the condition of the weather, syringing the trees with tepid water on fine days. It should be remembered, however, that mischief may be easily done at this season by using the syringe too freely. It will be well to vaporise the house with the XL-All Vaporiser just before the buds are about to open. In the case of earlier trees that are now coming into blossom, the atmospheric temperature may be from 50° to 55° at night, allowing a corresponding rise by day, and a moderate circulation of air. The pollination of the blossoms should be assisted at midday by the use of a soft brush, or rabbit's tail.

Strawberries.—As soon as the earliest plants are in blossom, efforts should be made on favourable occasions to secure perfect fertilisation by adopting artificial pollination, using a very soft brush when the pollen is dry. Maintain the atmosphere comparatively dry, and keep it in circulation. The atmospheric temperature should be 55° at night, allowing the usual rise by day. As soon as sufficient perfect fruits can be selected for the crop, fully expose them to the sun by carefully supporting them with twigs, and pinch off all the remaining fruits and blossoms. Give care to the watering of the plants and afford them applications of suitable manures; liquid obtained from the farmyard answers well or top-dressings of an approved artificial compound. The demands of early crops in these respects are not so great as are those of later ones. Successional batches of plants should be top-dressed with compost, enriched with soot and artificial manure, and be brought forward as may be necessary to meet the demands. We still follow here the old practice of resting the pots upon thin turves, which are placed upon stages near the glass, over beds of tree leaves that subsequently serve the purpose of affording bottom heat for summer crops of Melons and Tomatos. These beds promote beneficial humidity for the Strawberries during their early stages of growth. Spray the plants over head early in the afternoon of fine days, and keep the atmospheric temperature at 50° at night.

Early Melons.—Little is to be gained by raising Melons before the commencement of January, but plants raised in the present month, if cultivated under favourable conditions, should yield ripe fruits by the end of April. Seeds should be sown singly in 2½-inch pots filled with moderately moist, fine compost. Plunge the pots in a hot-bed, and cover each pot with a shaded piece of glass, placing them in an atmospheric temperature of 70° at night. No water should be applied to the soil until the plants appear. At this stage they should be given a light position near the glass; syringe them daily, and do not allow the roots to suffer from want of water.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Planting of bush fruits.—It is necessary to make new plantations from time to time to replace old bushes that have ceased to be profitable. The fresh bushes should be planted by themselves on a piece of ground where they can be easily protected from the birds. The ground should be trenched and enriched with a liberal application of manure, as the soil cannot easily be made too rich for bush fruits which generally occupy the same ground for several years together. Spread out the roots carefully when planting, and do not plant them too deeply, but tread the soil firmly about the roots as the work proceeds. Spread a mulch of half-decayed manure over the ground after the work has been completed, and do not prune the bushes until later in the spring. Gooseberries and Currants should be allowed a distance of 5 feet between the plants and 6 feet between the rows. Black Currants require 1 foot more space between each plant, and the same additional space between the rows. Black Currants will bear freely in a more shaded and moist situation than Red or White Currants, which thrive best in a lighter soil.

Pruning bush fruits.—The bushes on old plantations should now be pruned, unless buds are very troublesome. Thin and shorten more severely the spurs in those varieties of Gooseberries that are required for dessert, shorten the spurs on the Red and White Currant bushes to two or three buds and the leading shoots to a length of 8 inches. Remove the old wood from the Black Currant bushes and leave the young and vigorous shoots unpruned. When the pruning has been completed, collect all the shoots together and remove them to the fire heap. Apply a good dressing of manure to all the bushes, digging it in very lightly, so as not to cause damage to the roots. Dust all the bushes over occasionally with lime and soot, when the shoots are damp, as this will greatly assist in keeping away the birds. If cuttings of any of the above-mentioned fruits are required for increasing the stock, select well-ripened shoots and tie them in bundles and, after labelling them, heel them in under the shade of a north wall until they are required, or such time as they can be properly prepared for planting.

Raspberries.—If Raspberries have still to be planted, the work should be taken in hand at the first opportunity. The ground for Raspberries requires to be prepared as thoroughly as I have recommended for small fruits, but in subsequent seasons the spade should not be used on the ground, or the surface roots will be destroyed. Plant the canes at distances of 2 feet apart in rows, and allow spaces of 5 feet between the rows. Train the canes to strained wires made secure to iron uprights or strong posts about 5 feet in height. Cut the canes down to 6 inches or 1 foot from the ground when they are about to break into growth in spring. Old plantations that were thinned in the autumn will only require to have the canes trained to the wires, leaving them about 6 inches apart. Apply a mulch to the ground. Autumn-fruiting varieties should be cultivated in all gardens, and a more shaded position should be selected for these. They will require to be cut down to the ground early in the spring.

Top-dressing and manuring.—Any trees growing against walls, or any Apple and Pear trees that usually carry heavy crops of fruit, and trees that show signs of becoming exhausted should now be given attention. All such trees should have the surface soil removed down to the roots and replaced by good loam, wood ashes, and a liberal sprinkling of bonemeal; later a good dressing of manure may be applied.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to Lord ALDENHAM, Aldenham House, Elstree, Hertfordshire.

Seed-sowing.—This work must now be given serious consideration. Although one may easily sow seeds too early, at the same time every endeavour must be made to prolong the season of the most important vegetables during as long a period as possible. Consequently, it is now necessary to make small sowings of many kinds under glass.

Onions.—It is the rule more than the exception to raise a portion, if not the whole, of the crop under glass and transfer the plants to their permanent positions in due course. This practise has many advantages over that of sowing in the open, the principal ones being the early maturation of the bulbs, and the comparative immunity such plants have to attacks of the Onion fly. The present year promises to be one of exceptional interest to Onion-growers, owing to the large inducements offered in prizes for a new variety. But whether the Onions are intended for exhibition or not, I strongly advise that the plants be raised under glass. The seed should be sown in well-drained boxes at some date from the 10th to the 15th of the present month. Only a gentle heat is required, such as that afforded by a Vinery or early Peach house, which has just been started; hard forcing at any time must be avoided.

Leeks.—These should be treated like Onions, but if extra fine specimens are required early, a small quantity of seed may be sown in 3-inch pots, and the seedlings potted on into 32's (6-inch pots) when ready.

Cucumbers.—These should be sown in a light compost singly in small 60-size pots and raised on a brisk bottom heat. Very little water will be required until active growth commences, and this should be warmed to the same temperature as that of the atmosphere of the house.

French Beans.—To maintain a regular supply of Beans, fresh sowings should be made in pots at this season every fortnight or three weeks. Pots measuring 7 or 8 inches in diameter are best. These crops should be raised in the forcing house. Plants of Ne Plus Ultra and Canadian Wonder which are in bearing should be given liquid manure at every other watering; maintain a moist atmosphere where these are growing, or red spider will be certain to cause trouble.

Cauliflowers.—Sow a small quantity of seeds of Magnum Bonum and Early Giant in boxes, and raise them in a temperature of about 50°. Any forcing varieties which should have been sown last month ought now to be ready for potting off singly into pots having a diameter of 3 inches. Varieties such as Snowball and Early Forcing answer well for forcing early, and may be kept in a gentle heat till the heads are ready for cutting.

Lettuce.—Sow both Cabbage and Cos varieties for early supplies, and if from any cause the winter supply is getting short, sow Harbinger, and prick the seedlings out when ready into boxes, putting them 3 inches apart and affording them an atmospheric temperature of about 55°. These, when quite young, may be cut in the same way as Mustard and Cress, and they then make a tender ingredient for the salad bowl.

Seakale, Rhubarb and Chicory.—Introduce these to the Mushroom house as necessity requires. Sow seeds of the small salads once each week. Make preparation for protecting Celery and other tender vegetables with suitable material.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

The resting season.—The present being the quiet season for most Orchids, particular attention should be paid to all plants that are more or less inactive. Their treatment during this period involves even more care and thought than are required during the season of growth. The term rest, so often misunderstood, does not imply a periodical shrivelling of plants owing to the withholding of water and reducing of temperature. What the plants require is gradual and natural cessation of growth, as far as outward appearance goes, for a longer or shorter period according to the habit of the different species. If all Orchids were alike in their needs, it would make the resting season a much less anxious time for the cultivator, but they are not; therefore the grower has always to be on the alert, and give to each plant the attention it needs during this state of comparative inactivity. When a number of different species and hybrids varying so much in their time and manner of resting are grown together in one house, it is impossible to arrive at a common method of treatment that will suit all alike. It becomes, however, necessary to adopt what one may term a compromise as regards temperature and atmospheric conditions, to which the plants are perforce obliged to be made to submit in the compartment at command for their cultivation. Orchids that rest naturally during our winters not only require a lower temperature, but also less moisture in the atmosphere and at the roots. Nevertheless, the materials should not be allowed to dry excessively. Independently of the necessity in the case of many species for a proper resting period to ensure their satisfactory flowering, such rest is equally requisite to ensure their future growth. Hence the obligation to provide a cooler, drier atmosphere, and to afford water to the roots only in sufficient quantities to keep leaves, pseudo-bulbs, and roots in a plump and healthy condition. All the species of Orchids that require to be kept dry at the roots during their season of rest will be able to benefit by this to an extent depending upon the condition under which they have been grown during the last and preceding seasons. If the leaves and pseudo-bulbs are well developed and properly matured or solidified, especially the evergreen species, they will be the better able to bear a lengthened period of drought without shrivelling to an extent that will injure the foliage.

Temperatures.—The atmospheric temperatures of the various departments for the present should be as follow:—**Stove** or **East Indian house:** By day, 68° to 75°; by night, 60° to 65°. **Cattleya house:** By day, 60° to 65°; by night, 55° to 60°. **Intermediate house:** By day, 58° to 62°; by night, 53° to 56°. **Cool** or **Odontoglossum house:** By day, 54° to 58°; by night, 50° to 54°. The outside weather must be considered at all times, and the higher or lower figures maintained accordingly. A few degrees lower than the lowest will not cause any injury in severe weather, such as we are experiencing here at the time of writing (January 4), whilst 10° more than the highest day reading when it can be obtained by solar heat will be beneficial.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

The warm fernery.—Adiantum cuneatum is one of the first species of Ferns to start into growth in the New Year, and it is cultivated more commonly than any other species, for the plants lend themselves to numerous decorative purposes, and are acceptable at all seasons of the year. If any of the plants are intended for exhibition, they should be prepared for repotting. All the old fronds and any younger ones that are infested with insects should be carefully removed, and the old frond-stems cut out, but upon no account cut the plants down to the surface soil, as is sometimes done simply to save labour, the necessary time must be allowed if fine specimens are desired, and to cut off all the young fronds causes a great check to the plant. If the fronds are thin or scarce after so much cleaning, place three or four small thin stakes round the sides of the pot and a piece of twisted matting round the stakes to keep the remaining fronds in an upright position; another reason for not cutting the plants back too severely is that the young fronds which appear almost directly afterwards, come up so plentifully that as a result they become very weak, tender, and crowded at a season of the year when there is very little sunshine or light; the amount of moisture essential for the well-being of the plant, therefore, causes the mass of young fronds to suffer injury from damping. The present is a good time to collect any seedling Ferns that have appeared in the pots containing other plants, as these make by far the best specimens. Adiantums do not succeed well when cut up and quartered, as they are sometimes treated for purposes of division; it is much better to throw away old plants that have grown to too large a size and pot on others that are younger. It is a good plan to have a shelf near the roof in a fernery with an inch of board on each side, just sufficient to hold that depth of ashes. This shelf can be used for accommodating Gymnogrammes of the finer varieties, as no place in a fernery suits these plants so well as a position that is close to the glass. Such a shelf proves to be a splendid seed-bed, and young plants of almost all the varieties in the house will appear from time to time. It is useful also to cut a few of the spore-bearing fronds and place them in the water used for watering the plants and for damping down the surfaces in the house; by this means the spores are distributed.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

The pleasure grounds.—It is worthy of notice the number of common yet popular spring, summer, and autumn-flowering plants that remain effective even during the winter months if left in groups undisturbed over that period. Take, for example, the well-known Lunaria annua (Honesty). This plant, which flowers in such profusion from early in May through July, and has flowers of various shades of colour, produces silvery seed-pods in autumn, and now, when the seeds have fallen and the silver lining to the pods has become more fully exposed, the effect is beautiful. In the grounds here at the present time, as seen from a distance, a bed of the perennial Phlox stands out quite a conspicuous feature in a garb of nut-brown. The different types of Aster, such as Amellus, several shades lighter than the Phlox, make a good contrast. Epilobium, or the Willow herb, when confined to a limited space, is very useful for producing a good effect in winter. Good-sized clumps of Solidago present a very imposing appearance with their light plume heads. There are many ornamental grasses, a conspicuous sort being Eulalia zebrina, with its elegant arching leaves, so effective during summer and winter. Numerous plants of other species, which are usually cut down early in autumn, may with advantage to the plants, apart from the good effect they have in the grounds, be left standing until late in winter or early in spring.

Roses.—Any contemplated planting which has not been already carried out would be better postponed for the present. In preparing the ground for Roses deep cultivation should be practised and proper drainage afforded; these conditions are necessary whatever the nature of the soil may be. A fibrous root system near to the surface is most desirable in the plants; therefore do not bury rich farmyard manure too deeply, but rather make up your mind to give frequent surface dressings in subsequent seasons. We have now been covering the ground with such dressings, the work having been deferred with the object of allowing slight frosts to pulverise the surface soil. At the same time we are freely intermixing with the dressing some branches cut from Yew trees for protection. In preparing the ground for planting Roses in our somewhat cold, wet, chalky soil, a liberal addition of gravel has the effect of inducing the plants to make freer growth and better-coloured foliage.

Protection for tender plants.—Give attention to providing protection for tender subjects, such as Gunneras, which may be covered with bracken fronds, over which a wire basket pegged down affords good protection. The Pampas grasses may be matted up. Hollyhocks, Montbretias, and similar plants, when allowed to winter in the open, need top dressings of cocoa-fibre, rough peat, or coal ashes. Up to the morning of January 3, when we registered 17° of frost, Veronica Andersonii, covering a border measuring 60 feet by 3 feet, retained its summer beauty. On January 4 we had 20° of frost. The rainfall here for 1907 amounted to 27 inches.

PUBLIC PARKS AND GARDENS.

By JAMES WHITTON, Superintendent of the Parks and Open Spaces in the City of Glasgow.

The gardener's opportunity.—Seeing that in the matter of park-management a wider opening is being made for gardeners, those whose thoughts and inclinations are in this direction should study to train and equip themselves for the best positions this branch of gardening can afford. A thorough all-round training in his profession is absolutely necessary to enable a man to successfully discharge the duties which are inseparable from the office of park superintendent in a large city. The more important the charge the greater is the necessity for this. Where the parks department is a separate and distinct division, the superintendent is usually responsible for all the general work, excluding, of course, the legal and financial, and other special work such as surveying and architecture, though he is required to be in attendance at the committee meetings when all matters are being discussed. He may have to design and lay out new parks and playgrounds, and carry out the work with the help of his regular staff, with such extra assistance as the case demands. He must be able to supervise and direct the various tradesmen employed, see that all work is properly executed, keep the time and cash books, make out the necessary returns and reports for the committee, and conduct the general correspondence of the department. This will bring him into contact with the town clerk and heads of the various municipal departments, with whom he should always keep on friendly terms, as there is nothing more conducive to failure than having his department at friction with another department, for all are integral parts of a huge machine which must work in harmony, otherwise there will be a waste of energy, and, upon discovery, the result is bound to be in the removal of the cause.

Method of training.—Assuming that the young gardener is perfecting himself first in the practical work of his business, he should endeavour to prove himself a skilled tradesman. He should be neat and smart in person, prompt and polite in his speech, courteous and obliging in manner; in his daily life practising the grand old maxim, "Whatever is worth doing is worth doing well." In his spare time he should learn the science of his business, and he will find plenty of books to assist him in doing this, but remembering always that these are but means whereby, by strict application, he may attain perfection. When he has served five or six years in a good private garden he might profitably spend a year or more in a good plant nursery, where he could learn more about the propagation and handling of trees and shrubs than is possible in a private garden. If he desires to further increase his knowledge of plant life, a couple of years spent in a first-class botanical garden will be of great advantage to him. Thereafter he may act as a foreman in good gardens or public parks until he is able to secure a situation as a head gardener, where he can show his ability and skill as a cultivator and manager of men, also his ability to carry out work on his own initiative. He will then have an opportunity to learn how to buy materials, keep books, and his horizon will thus be widened generally as he gains increased knowledge of men and affairs. There may be exceptional cases of gardeners being given the care of public parks without having first held responsible positions, but these cases are in the minority. The appointment of responsible officials is a matter of importance in any community, and corporations and local authorities usually make thorough investigations into the credentials of candidates for their appointments.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and fully signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JANUARY 14—
Royal Hort. Soc. Coms. meet. Hort. Club meet. Ann. Meet. of Scottish Hort. Assoc., Edinburgh.

WEDNESDAY, JANUARY 15—
Brixton, Streatham, and Clapham Hort. Soc. Ann. meet.

THURSDAY, JANUARY 16—
Linnean Soc. meet. Kent County Chrys. Soc. Ann. meet.

SATURDAY, JANUARY 18—
Soc. Franc. d'Hort. de Londres Annual Dinner. German Gardeners' Soc. meet.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, January* 8 (6 P.M.): Max. 49°; Min 34°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, January* 9 (10 A.M.): Bar., 29·6, Temp. 37°; *Weather*—Fair.
PROVINCES.—*Wednesday, January* 8 (6 P.M.): Max. 43° Land's End; Min. 35°, Scotland N.E.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—36·6°.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—
Sale of Dutch Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY AND FRIDAY—
Herbaceous Plants, Bulbs, and Tubers, Azaleas, &c., at 12; 1,000 Roses of sorts, at 1.30; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—
Hardy Border Plants, Perennials, Bulbs, and Tubers, at 12; 3,600 Roses of sorts, at 1.30; Azaleas, Palms, &c., at 5; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
Imported Dendrobiums and other Orchids in variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Small Holdings.

In our issue of last week we printed an exposition of the somewhat complicated provisions of the Small Holdings Act, concerning which a good deal is being spoken and written at the present time.

Some enthusiastic people see in it a sort of universal cure for all the evils resulting from rural depopulation, whilst others, less sanguine as to the reality of the benefits it is expected to secure, assume a detached attitude of philosophic doubt regarding it. Probably both classes of persons will be able to point to facts in the future which will go to support their present position. For our own part, we do not range ourselves with those who would pour cold water on the movement, but we cannot blind ourselves to the difficulties which will have to be satisfactorily met if the new order of things is to become a permanent success.

There is no doubt as to the existence of land hunger, and it is the less real because of the obvious fact that many who give expression to it most loudly are clearly destitute of all knowledge as to what is involved in its satisfaction. But it still remains to be seen just how far the class which can best afford to appease it, with advantage to themselves and to the community, are prepared to accept also the attendant risks. A small allotment, such as a labouring man can cultivate in his spare time, is one thing, but the management of what, to all intents and purposes, is a small farm or market garden is quite another. In fact, for the purposes of ownership or occupation of land under the new Act, we may divide the intending applicants into two sharply-defined groups, those who do and those who do not possess a practical knowledge of the essential matters pertaining to the cultivation of the soil. It is tolerably certain that the latter class will be a fairly large one, and it ought to be distinctly understood that persons in this position will run serious financial risk in gratifying their desire for land. The management of a farm or a market garden is by no means the simple thing it may appear to be as long as one's living is not dependent on its success; and any one who has had actual experience of these matters is only too well aware that it is a business which demands considerable knowledge of a practical sort, and that it does not by any means consist solely of the kind that can be picked up in a few weeks from books. The countryman born and bred has this great advantage over a townsman who aspires to a rural life—namely, that he has learnt from boyhood, and almost unconsciously, those practices which long experience has proved to yield good results. It is very likely that he may often be unable to give an intelligent reason for the various things he does, but rule of thumb is not the monopoly of any one trade or profession; and the results of an operation are not necessarily the worse because the causes for its performance are not fully understood.

But assuming that the new occupant or owner is already acquainted with the business of cultivation, there will presently loom up the question of markets. For if the movement is going to develop on a scale at all commensurate with the expectations of those who have interested themselves in it, the existing conditions of things in regard to this very important question of markets will inevitably have to undergo material alteration.

It is by no means the same thing for a number of people to engage severally in the cultivation of vegetables, or other produce, in quantities which are hardly more than sufficient for their own needs, as to embark on a business the success of which depends on the prices in a fluctuating market. This aspect of the matter is sufficiently serious even in the case of the larger grower, with reserve capital at his back. But the individual financial resources of a member of the class we are now considering will naturally not be large, and, when the local market is satisfied, must often prove quite inadequate to meet profitably the expenses unavoidably incurred in connection with the disposal of produce.

Some sort of co-operative organisation is obviously indicated, otherwise the profits which ought to go to the producer will tend, even more than at present, to collect in the pockets of the middleman, or, worse still, in those of the moneylender. Many suggestions as to methods of co-operation have been advocated, and some plans have been found to work well abroad. It will be necessary, however, to elaborate for ourselves the particular practice which will suit our own requirements; the problem is far too complicated to be solved by the mere importation and adoption of any existing foreign practice in its entirety, although much may be learnt by the study of methods which have proved satisfactory to our neighbours. It would be foolish, perhaps, and certainly premature, for us to advocate any particular plan of co-operation just now, but it is important that the necessity for some practical scheme should be borne in mind. The difficulty has inevitably to be faced, and upon its satisfactory solution will depend, in no small degree, the ultimate success of the movement as a whole.

It ought not to be necessary to remind any one who is contemplating embarking on the experiment of a small holding, the cultivation of which will occupy the whole, or, at any rate, the greater part of his time, and will thus render him proportionately dependent on its results, that it pays over and over again to see to it that he secures good land. It is far cheaper in the long run to take a good, if smaller, piece at a higher price or rental, than a larger one of poor quality because less money is asked for it. But although such advice is plainly in accordance with the dictates of common sense, experience unfortunately proves that it is too often ignored by those who ought to have known better. We have ourselves seen men, brought up on the land, who, after saving money, have put their small capital and their energies into a little farm of poor land, there to eat out their hearts for the rest of their lives in the struggle sometimes in vain—to make both ends meet. It is impossible to make a silk purse out of a sow's ear, and it is almost as hard to make a fair living out of a hungry soil. Such land takes all and gives little, and that grudgingly, in return for the labour spent upon it.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees of this society will take place in the Royal Horticultural Hall, Vincent Square, Westminster, on Tuesday, January 14. A lecture on "Royal Horticultural Society's Exhibitions" will be delivered at 3 o'clock by Mr. J. GREGORY. The lecture will be illustrated by lantern slides.

HORTICULTURAL CLUB.—The next house dinner of the club will take place on Tuesday, January 14, when Mr. E. A. BUNYARD will lecture on "Recent Advances in Plant Breeding," with special reference to Mendel's work.

NATIONAL SWEET PEA SOCIETY.—We have received a circular from the honorary secretary, Mr. C. H. CURTIS, relating that there will be a further trial of Sweet Peas at the University College Gardens, Reading, during 1908. The trial will be an independent one, and under the management of Mr. CHAS. FOSTER. Not fewer than 15 seeds of each variety should be sent, and they should reach Mr. CHAS. FOSTER, Assistant Director in Horticulture, University College, Reading, on or before January 14. The sender should indicate the colour section to which each variety belongs, whether it has waved or plain flowers, and whether he wishes to have it tested by the side of any standard variety. This information should be on a separate sheet of paper, and if a duplicate copy is sent to the secretary, it will be esteemed.

THE SWEET PEA ANNUAL. We are asked to state that the *Sweet Pea Annual* and schedule of prizes for 1908 will be ready for distribution on or about January 16.

BOTANICAL MAGAZINE.—The issue for January contains illustrations and descriptions of the following plants:—

PHILODENDRON × CORSINIANUM, tab. 8,172.—This is a garden hybrid raised by the firm of Messrs. MAKOY, of Liège, for which they were awarded a Certificate of Merit by the Royal Agricultural and Horticultural Society of Ghent in 1887. Its parentage is not known, but Mr. N. E. BROWN states that judging from the purple tint on the under surface of its leaves, a coloration which is unusual in the genus, it is possible that P. verrucosum, Mathieu, may have been one of its parents. The hybrid is a climbing plant of somewhat slow growth; the Kew plant which afforded material for the present figure was acquired in 1898, and is now only about 8 feet high, with a spread of about 6 feet. The rich purple-crimson colour developed on the large spathes is sufficient to make the hybrid a good garden plant. Mr. WATSON, who appends a note on the cultivation of Philodendrons, remarks that P. × Corsinianum is the only hybrid Philodendron that has been raised. Plants of this genus are very desirable subjects for clothing pillars, Palm-stems, and back-walls in tropical houses; their leaves are no less handsome than their inflorescences.

PÆONIA MLOKOSEWITSCHII, tab. 8,173.—There are three yellow-flowered Pæonies from the Caucasus, P. Wittmanniana, Stev., P. macrophylla, Lomakin, and the present species P. Mlokosewitschii. All three species have affinities with P. corallina, Retz, and Dr. STAPF appears to think it probable that they may eventually be reduced to forms of that species. P. Mlokosewitschii was collected by MLOKOSEWITSCH near Lagodekhi, in the eastern part of the central Caucasus, and the present figure has been prepared from specimens sent to Kew by Mr. W. E. GUMBLETON, Belgrove, Queenstown, who obtained the species from Mr. MAX LEICHTLIN, of Baden-Baden. Mr. WATSON describes the species as the most handsome of the yellow-flowered Pæonies, and it is as hardy under cultivation as they have proved.

VIBURNUM UTILE, tab. 8,174.—The present drawing of this species has been made from materials supplied by Messrs. JAS. VEITCH & SONS, who raised it from seeds sent home by their collector, Mr. E. H. WILSON. It was first discovered near Ichang by Mr. T. WATTERS (British Consular Service) in 1880. Mr. W. BOTTING HEMSLEY, who is responsible for the description, remarks that there are upwards of 50 species of Viburnum now recorded from China. Mr. W. J. BEAN states that this new species, as seen growing in the Coombe Wood Nursery last spring, gave the impression that it would eventually prove one of the most desirable of recent introductions from China. It promises to succeed on ordinary, well-cultivated ground, and may be increased by cuttings like the other species.

HERBERTIA AMATORUM, tab. 8,175.—Mr. T. F. CHIPP describes this South American species, seeds of which were forwarded to Kew in 1903 by Dr. C. B. CANTERA, of the Natural History Museum, Monte Video. Corms raised from these seeds flowered for the first time in a greenhouse in May, 1907. Mr. WATSON states that this is the most handsome species of the genus so far brought into cultivation. The porcelain-blue flowers are very fugitive, but the plants bloom continuously for several months. The plants require protection from frost, and succeed best in a sunny position in a frame or greenhouse.

PSEUDOLARIX FORTUNEI, Mayr, tab. 8,176.—This species was referred to by Mr. E. H. WILSON in a letter published in our issue for November 16, 1907. It is the species erroneously identified by LINDLEY in the *Gardeners' Chronicle*, 1854, with his Abies Kæmpferi of 1833. The confusion arose owing to the discovery of the species taking place many years after the name Abies Kæmpferi had already been applied to another plant, this being followed by a wrong identification of species with the latter. Mr. W. BOTTING HEMSLEY enumerates these and other particulars, and states that the late Dr. M. T. MASTERS accepted Mayr's name (*Journ. Linn. Soc.*, 1902, vol. xxvi., p. 557, and 1906, vol. xxxvii., p. 424). The tree succeeds but poorly at Kew, and it requires a large proportion of stiff loam mixed with the staple. It is a very beautiful deciduous tree, and in spring the foliage is of a delicate shade of yellowish-green; in autumn the leaves develop a rich gold colour before falling.

"JOURNAL OF THE BRITISH GARDENERS' ASSOCIATION."—The third number of this quarterly journal contains articles on "Testimonials," by A. C. BARTLETT; "A Gardener's Reflections," by G. F. TINLEY; "Is Gardening a Luxury?" by "J. W."; "Trade Unions—Masters and Men," by Mr. W. H. DIVERS; also unsigned articles on "The Status of Gardeners," "Gardeners' Agreements," "Wages, Work, and Worth," "The Ordinary Male Gardener," and other subjects. A report is given of the conference on "Examinations for Gardeners," held in the Royal Botanic Society's Gardens on September 12, also of the meetings of the B.G.A. Council, &c. The copies are 3d. each, and may be obtained from the Secretary, Talbot Villa, Talbot Road, Isleworth.

DR. PLOWRIGHT.—On January 6 the Mycologist to the Government of Ceylon, Mr. T. PETCH, B.A., B.Sc., was married at King's Lynn to Miss EDITH MARY PLOWRIGHT, the only daughter of Dr. C. B. PLOWRIGHT, whose communications on mycological matters have for many years appeared in these pages.

ANNUALS AND DIRECTORIES.—Numbers of these indispensable books find a place on an editor's table at the present season. First in importance to the gardener, and more especially the trade gardener of almost every grade, are the garden directories.

The Horticultural Directory and Year Book for 1908 in certain points is more compendious than others sent to us for review, and includes a list of county staff instructors in horticulture, with names and addresses; many garden recipes, recipients of the Victorian Medal of Honour, a descriptive list of certificated plants, &c., and Awards of Merit granted by the R.H.S. and London Horticultural societies from October 9, 1906, to September 17, 1907. An equally useful list is that of Chrysanthemums certificated by the National Chrysanthemum Society from October, 1906, to October, 1907; those of the National Sweet Pea Society on August 20, 1907; and of the National Dahlia Society and London Dahlia Union, 1907. The list of the principal fruit and flower salesmen and commission agents in London will be appreciated by growers and sellers residing in the country districts who may be desirous of bringing their productions to the notice of people in town.

The Garden Annual and Almanack, issued by Mr. W. ROBINSON, proprietor of *Gardening Illustrated*, is a compilation on similar lines to the *Horticultural Directory and Year Book*. Its contents consist in great part of an alphabetical list of nurserymen, seedsmen, and florists in the British Isles, and a select list of the leading men in these branches of trade in European countries, Germany, France, Holland, and Belgium. This list of foreign nurserymen and seedsmen might be made much more comprehensive. The list of the chief public parks and gardens increases in number with the years. In this list we find Chiswick included, notwithstanding the garden of the Royal Horticultural Society has been removed to Wisley, in Surrey. In a list of the principal horticultural societies, Mr. ED. MAWLEY is still mentioned as the secretary, but several years ago Mr. MAWLEY was succeeded by Mr. BROUSSON, and Mr. BROUSSON having recently retired, Mr. H. H. THOMAS now fills the position. A list of the new plants, fruits and vegetables certificated in the period November, 1906, to November of 1907 by the chief horticultural societies is appended towards the end of the volume, together with a variety of useful tables and postal information.

Vinton's Agricultural Almanack and Diary for 1908. This publication will appeal more to the stock breeder and farmer than to any others. The work is in entirely new and improved form, and it is increased in size. The chief feature is the inclusion of a full diary for the year, four days to the page, along with cash receipt and expenditure accounts, two pages per month, with a like space devoted to monthly breeders' tables and calendar. A review of the agricultural year and a monthly calendar of the operations of the farm are given, along with a large and complete collection of statistics, tables, &c., hitherto only available by consulting numerous publications. A useful publication, compiled to meet the requirements of landowners, farmers, estate agents, and others interested in country life and pursuits.

The Writers' and Artists' Year Book, 1908.—A directory for professional writers, artists, and photographers, and containing a list of papers and magazines, with details of articles and illustrations required; a list of American journals and magazines; lists of publishers in this country and America; press-cutting agencies; photographers who supply prints for reproduction; literary agents, &c.

The Gloucester Diary, published by the Gloucester Railway Carriage and Wagon Co., Ltd., Gloucester, contains, besides the usual calendar and almanac for 1908, brief notices of the city of Gloucester, its many royal charters, now in the custody of the town clerk; and of Berkeley Castle, the docks, and of the importance of the carrying trade of the port; the cathedral, &c. The advertisements, which take up the major portion of the publication, concern the manufactures, many and important, of the Gloucester Railway and Wagon Co.

Diary and Note Book.—Messrs. HAYWARD-TYLER & CO., LTD., 99, Queen Victoria Street, London, send us a convenient little pocket diary and note book for 1908, containing useful information on the matter of the water supply to estates, gardens, mansions, &c.

Webster's Foresters' Diary and Pocket Book.—This convenient diary and pocket book, prepared by Mr. A. D. WEBSTER, contains a vast amount of information useful to foresters and gardeners, and is already well known by a large number of readers who annually look forward to the publication of each new edition. An enumeration of the prices for contract work, a list of foresters in Britain, trees for various kinds of soil, tables for measurement of timber, and hints on most details of forestry work, with [illegible] articles on such subjects as "Afforesting Waste Lands," "Forest Law," &c., are but some of its contents. It is published by WHITAKER RIDER & SON, LTD., at the price of 2s. 6d.

ROYAL METEOROLOGICAL SOCIETY.—At the annual general meeting to be held at 7.45 p.m. on January 15, the presentation of the Symons Gold Medal will be made to M. LEON TEISSERENC DE BORT, and an address will be delivered on "Map Studies of Rainfall" by Dr. H. R. MILL, president.

THE NICE AND MARITIME ALPS SOCIETY OF PRACTICAL HORTICULTURE will hold a horticultural show on April 2-5, under the patronage of the Prince of Monaco, the Minister of Agriculture, and others. Intending exhibitors should address Mr. A. BERRY, the president of the society, at 1, Avenue de la Gare, Nice, before February 15.

MESSRS. VEITCH'S EXHIBIT OF FRUIT.—Owing to a printer's error, we omitted to state in the last issue that the excellent exhibit of Apples and Pears shown by Messrs. JAMES VEITCH & SONS at the last meeting of the Royal Horticultural Society was awarded a Gold Medal

AGAVES AND SOIL DENUDATION.—Much trouble is caused in the South African veldt by the various agencies that tend to erode the surface of the ground, such as burning, excessive trampling, torrents, &c. The evil is being successfully combated, according to Dr. NOBBS, writing in *The Agricultural Journal of the Cape of Good Hope*, by planting the American "Aloe" (Agave) on the affected lands. Lines of these plants form effective barriers to the denuding effects of torrential rains, and, by catching the sediment as it washes down, the line of Agaves in the course of a few years becomes a terrace. In addition to the use just mentioned, a shelter is provided for other plants which spring up and form an additional mass of vegetation, whilst the young succulent leaves of the Agave afford a supply of palatable food during the dry season. The use of vegetation in arresting denudation is well known all over the world. Much of the barrenness that now forms so strongly marked a character of the higher valleys in certain Alpine regions of Europe is directly traceable to the carelessness or stupidity of the inhabitants, who destroyed the trees and scrub. By the removal of the barrier of vegetation, the mountain torrents have stripped the rock of its covering of earth, and desolation reigns in many a stony glen to-day where formerly the ground was covered by a vegetation of Pine and other trees.

MANOR HOUSE GARDENS, BASINGSTOKE.

(See Supplementary Illustration.)

THE residence of John Mares, Esq., is pleasantly situated on the south side of the busy town of Basingstoke, which is noted for the manufacture of agricultural implements. The gardens attached to Manor House are not extensive, but are kept remarkably well, and possess much interest. If Mr. Mares has a leaning to any particular phase of gardening it is the cultivation of Roses. The garden contains a remarkable collection planted in various methods and situations.

The Rose garden, which forms the subject of the supplementary illustration, is mainly composed of dwarf plants of Tea, H.T., and H.P. varieties. The soil is loam over chalk, and it suits Rose admirably; careful attention to occasional re-planting, together with the employment of a sufficient quantity of manure, have enabled remarkable results to be obtained.

Mr. Mares wishes to grow only the best varieties, therefore he is continually revising and adding to his collection.

Within the last three years the newer type of Rambling Roses, of which there are now so many charming varieties, has been planted in considerable numbers. A handsome pergola constructed of Larch timber in an artistic manner has been built, and this leads from the lawns to the kitchen garden in a southerly direction, and the situation—north and south—is an ideal one for the Roses. This has been planted with the best varieties, and the careful attention bestowed on the plants by the gardener, Mr. Neale, has brought about very satisfactory results. Such varieties as Lady Gay, Hiawatha, Mrs. F. W. Flight, the newer forms of Rosa Wichuraiana, as well as such varieties as Dorothy Perkins, Felicite-Perpetue, Mme. Abel Carrière, and Leuchstern have given much pleasure.

Considerable additions have been made during the present season. Standard Wichuraianas on the lawns, and many "pole" Roses have been added, as well as groups of such varieties as Richmond, General Schablikine, General Nabonnand, Cheshunt Scarlet, Mme. Abel Chatenay, Mme. Ravary, Gustave Regis, Lady Battersea, and Prince de Bulgarie.

Alpine plants are cultivated in considerable quantities, and a recently-constructed rockery by Mr. E. Ladhams, Shirley, Southampton, affords much scope for this style of gardening. Considering the short time that has elapsed, considerable growth has been made by the plants.

Herbaceous plants are given considerable space in two long borders flanking a gravel path leading to the Rose garden. Flowering shrubs are an interesting feature.

The glass department is but small. A lean-to Peach house, with the trees planted crosswise in the house, was a great success under that method of training. *A. Wanderer.*

FOREIGN CORRESPONDENCE.

JAPAN.

THE following paragraphs are extracts from the *Japan Times*, copies of which have just reached us, and are interesting as showing that the editor of that paper believed that the bulbs exported from Japan were consumed in Europe as food

EXPORT OF LILY BULBS

The export of Lily bulb as edible food is fast increasing. According to the returns of the Department of Agriculture and Commerce the total exported during last year reached 500,000 yen in value. The crop this season is expected to show some increase compared with the previous year. An increase of about 10 per cent. is expected in Kagoshima where the Lilies are cultivated in great abundance. *October 30.*

TO THE EDITOR OF THE *Japan Times*

SIR,—I note in your to-day's issue a small paragraph in reference to the export of Lily bulbs and beg to correct that article in so far as Lily bulbs exported from Japan to Europe and America are not used as a food product, but are simply purchased and cultivated on account of their beautiful blossoms.

A great many of them, especially Lilium longiflorum (Jap. Teppo yuri), are forced in greenhouses and are sold principally during the Christmas and Easter holidays. The other varieties like Lilium auratum (Jap. Yama yuri), the different varieties of Lilium speciosum (Jap. Kanoko), are planted in large masses in our gardens and parks, and are in such demand that hardly any well-arranged garden is without them.

The demand for these Lilies has increased from year to year and has been an excellent source of revenue to the Japanese farmers.

It is, however, necessary that the farmers should pay more careful attention to the culture of these bulbs and endeavour to eliminate some undesirable and diseased types, which they deliver mixed with the good types and which cause great dissatisfaction amongst growers abroad, and which will surely injure this trade in the future, which is now so promising to Japanese agriculture

Yours faithfully,

ALFRED UNGER (L. Boehmer & Co.).

Yokohama, October 30, 1907.

USEFUL SPECIES OF ACANTHACEÆ.

THERE are many members of the natural order Acanthaceæ that, blooming in the winter season, are especially valuable for the purpose of decorating the stove and warm greenhouse. Nearly all of them are natives of tropical regions; therefore, a structure in which a minimum atmospheric temperature of 50° or thereabouts is maintained is necessary for their cultivation. Most of them are of easy propagation and culture, their one drawback, viewed from the present-day standard, being that the individual blooms are somewhat fugacious in character; hence they are not of much value in a cut state.

As decorative plants, however, most of them are capable of maintaining a succession of flowers from one head or cluster for a considerable time.

Perhaps the most useful of all are the Jacobinias, in which genus are now included several plants that were at one time known by other names, and as such are often seen in gardens. Chief among the Jacobinias is J. chrysostephana, introduced from Mexico nearly 40 years ago, but it is only within the last decade or so that its merits have been fully recognised. This has been principally brought about by the splendid flowering examples that have been exhibited in recent years during the late autumn and early winter. With its crowded heads of golden orange-coloured flowers, this species is totally unlike any other occupant of our greenhouses.

Jacobinia Ghiesbrechtiana, under the generic name of Sericographis, has long been a favourite subject for flowering in winter. The tubular-shaped flowers of this species are scarlet, and, instead of being borne in closely-packed heads, are disposed in loose panicles. J. magnifica may be often seen under the name of Justicia carnea; it has flowers of some shade of pink. Of this species there are several forms, some of which were at one time regarded as distinct species. J. pauciflora is the proper name for that old favourite, Libonia floribunda. The pretty yellow and red tubular-shaped flowers of this species are borne throughout the winter months.

APHELANDRAS.

The brightly-coloured blossoms of some of the Aphelandras will be borne during the winter, but they are by no means limited to this particular season of the year. Perhaps the most regular in this respect is the oldest species of all, viz., A. tetragona, far better known as A. cristata. In this plant the flowers are arranged in a terminal decussate spike. They are rich scarlet, and make a goodly show when at their best, which, as a rule, is in late autumn and early winter. Other showy species are A. aurantiaca, A. Chamissoniana, A. ritens, and A. pumila, but, as above stated, they are not strictly winter-blooming plants.

JUSTICIAS.

Justicia calycotricha, syn. J. flavicoma, is almost the sole survivor of the numerous plants that were at one time included in the genus Justicia. It is, however, so pretty that it deserves extended cultivation. Like many of its allies, it branches but sparingly, and the flowers are borne in terminal heads. They are canary-yellow in colour, while the segments of the calyx are long and hair-like, thus giving to a head of bloom a distinct and fluffy appearance. It has also been known as Schauerta calycotricha.

PERISTROPHE SPECIOSA.

This species is a native of the Himalayas, and one of the hardiest of the winter-flowering species. The flowers are purple, and they are scattered over the entire plant which is of a branching habit. It is also known as Justicia speciosa.

DÆDALACANTHUS.

The members of this genus were formerly known as Eranthemums, and as such are still grown in most gardens. The most beautiful is Dædalacanthus nervosus, syn. Eranthemum pulchellum, whose blossoms are of a delightful shade of rich blue. Its Gentian-like colour gains it the admiration of all.

D. macrophyllus has curved flowers about 1½ inches long and of a purplish mauve tint, the lower lobes being of a deeper hue. The flowers are disposed in a loose, terminal, pyramidal-shaped, branching raceme. As a rule, this species does not bloom till after Christmas.

D. parvus, which was given an Award of Merit by the Royal Horticultural Society a few years ago under the name of D. Wattii, nearly resembles D. nervosus, but it is distinct therefrom. It grows little more than 1 foot in height, and the flowers are borne in short spikes, and individually are about 1 inch across, and of a deep bluish-purple with a slight metallic shade.

THE RUELLIAS

deserve especial mention, more particularly R. macrantha (see Fig. 16), whose flowers are larger than those of any other member of the order with which I am acquainted. It forms a somewhat upright-growing plant, while the solitary flowers are produced from the axils of nearly every leaf towards the upper part. They are trumpet-shaped, slightly curved, from 4 to 5 inches long, and about 3 inches across the expanded mouth. The colour is a kind of rosy purple veined with a deeper tint. This Ruellia will flower throughout the winter. There are other species, but this is much the best. W.

VEGETABLES.

EARLY SEED POTATOS.

THE early Potato crop in gardens is such an important one that no stone should be left unturned to ensure its success, and upon this success there is no question that the proper preparation of the tubers has a decided bearing. The man who selects his seed tubers at the time that the season's crop is lifted undoubtedly scores a valuable point, as he is able to give the sets special attention during the winter months, but there is much which may be done now to make up for neglect at that period.

In the first place, the available stock should be looked over, and as many sets of seed size as are likely to be wanted put on one side. These sets, in the case of early Potatos, should average about 2 ozs. in weight; they may be a little less, but should on no account be too small. I have seen early Potato sets not larger than marbles, while a tuber as large as a pigeon's egg is by many experienced gardeners considered a good size. Many scores of carefully conducted experiments have, however, proved the 2-oz. set to be the ideal size, and where the stock will permit of a choice being made, I would always advise the selection of this size.

If the stock of Potatos has been kept cool, there is little fear of shoots showing at present, but before they do show, say, the last week in January or the first week in February, the tubers should be set on end in boxes in a light and cool place. If the "eye" system of a Potato is closely examined, it will be seen that each eye consists of several buds, generally three, arranged with the most prominent bud in the centre and two smaller buds, one on either side. Now this central bud, because of its strength, invariably starts into growth first, and, also because of its strength, pushes a shoot which is much stronger than those pushed by its companions, should they ever have the chance of pushing any. This, however, they rarely have unless something goes wrong with the main shoot; they are merely nature's provisions against failure or sterility.

As priority and extra strength are the attributes bestowed by nature upon the central bud in each eye, so in like manner she bestows them upon the shoots which emanate from the large or rose end of a tuber; in other words, the shoots which issue from the large end of the tuber are invariably the earliest and [illegible]. From these facts we learn two valuable lessons: firstly, that the first shoots from [illegible] are the best, and, secondly, that the first shoots pushed from the rose or large end of a Potato are the very best that the Potato can give.

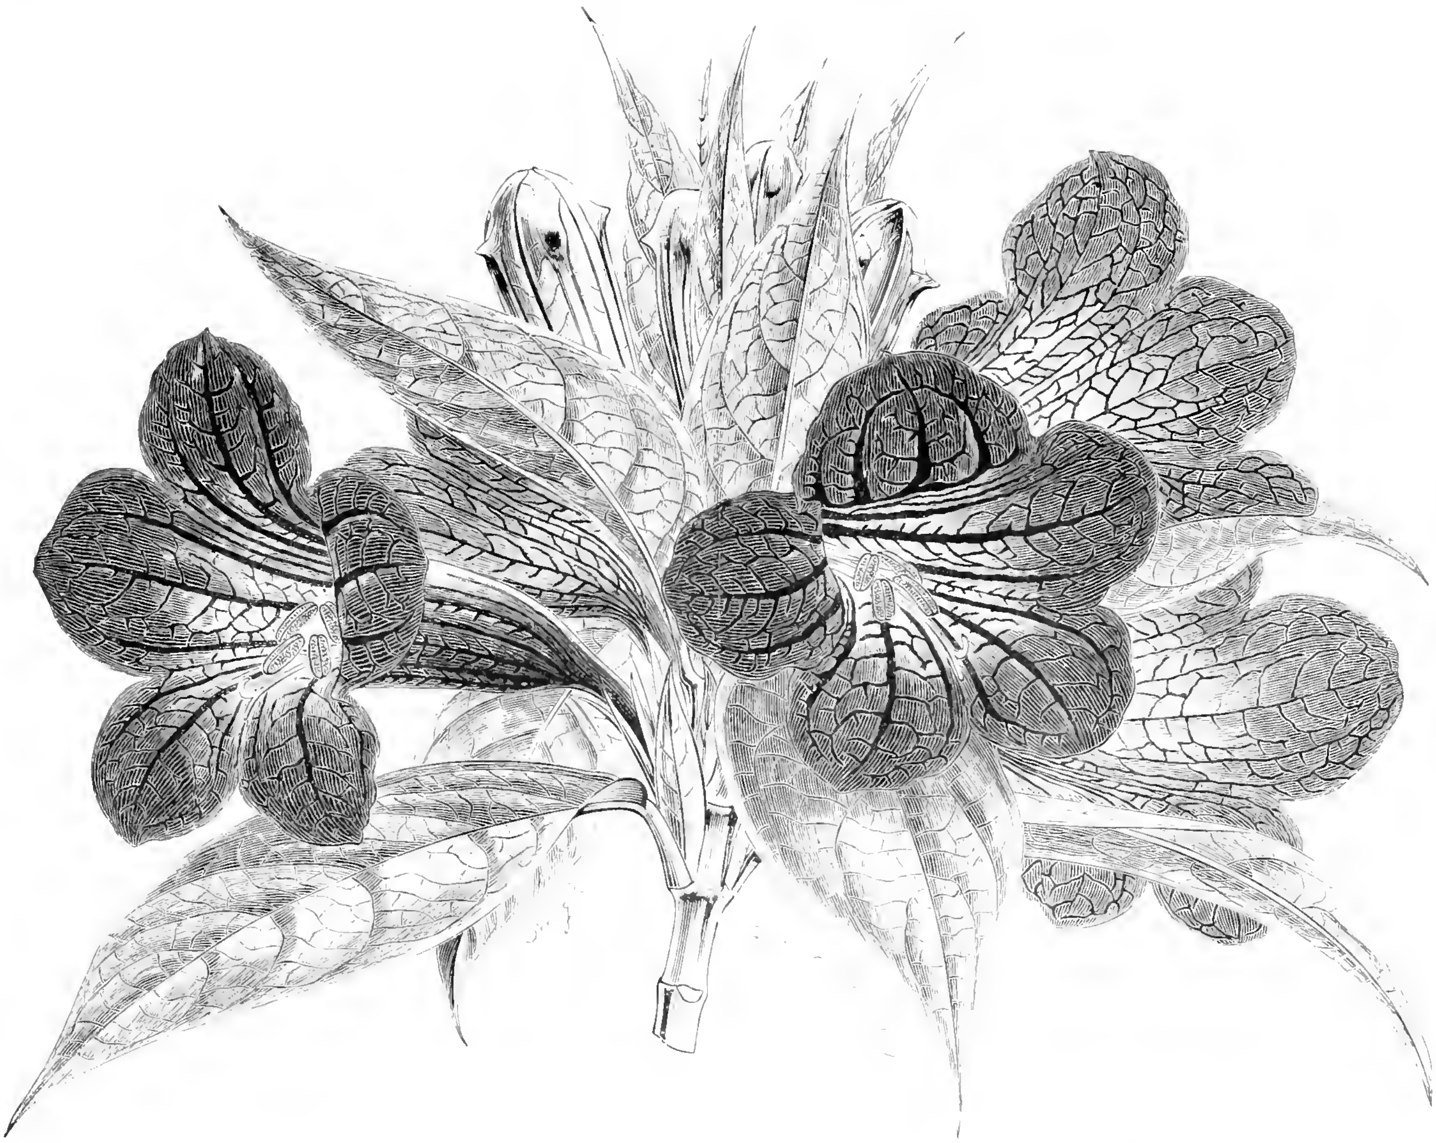

FIG. 16.—RUELLIA MACRANTHA: COLOUR OF FLOWERS ROSY-PURPLE, VEINED WITH A DEEPER TINT.

Armed with this knowledge, we at once see the explanation of the practice followed in all good gardens of placing Potatos on end to sprout. It may be, probably is, a rule of thumb method with some practitioners, but all the same they have seen the good results attending the system and are perfectly justified in following it.

As already indicated, the end of January or the beginning of February is the best time for up-ending tubers wanted for planting early in March, but, in view of what has been written, I hope that readers will realise that rather than wait for any given date, the sets should be placed on end directly the least sign of growth appears. Some lucky people are able to purchase special Potato sprouting boxes, or have them made, and there is no question that these are a capital investment, for not only do they admirably answer the purpose of sprouting Potatos, but they are extremely useful in a garden in many other ways. Ordinary cutting boxes make good substitutes, while I have seen many a fine lot of tubers started in chocolate boxes obtained from the grocers.

The tubers should, as before stated, be placed with the large end up, and they should be so packed that they just touch each other. They should then have a place in a light shed, where they will be safe from frost. Some growers make a practice of covering the sets over with sacks or other cloths, giving as a reason that the shoots push more quickly in the dark; this may probably be the case, but it is a practice with which I, personally, do not agree, for shoots pushed in the dark must be comparatively tender, and, moreover, are blanched and drawn.

As the shoots develop, their number should be strictly limited, as many shoots mean many and small tubers in the resulting crop; this fact may be taken advantage of by those whose taste runs in the direction of small Potatos. The majority, however, like to have Potatos of good size, and they will, therefore, be well advised to rub off all shoots but two, or at the most three, at the rose end of the tubers. Every care should be taken of these, and at planting time they should be somewhere about ½ inch long, or a little longer, sturdy, semi-tuberlike in shape, and of a deep green or purple colour. *E. J. C.*

OUT-OF-DOORS VINE BORDERS.

VINES which are growing exclusively in outside borders, and are to be subjected to forcing in January or later, should receive attention at their roots. A quantity of stable manure and tree-leaves in about equal parts should be well mixed together and be turned several times to allow the rank heat and steam to pass off. This heap is best if prepared some weeks in advance. The surface of the vine border should be lightly disturbed with a digging fork to the depth of 3 or 4 inches, or down to the surface roots. The soil thus loosened should be removed and be replaced with a like thickness of prepared compost, consisting of four parts good loam, one part of old lime rubble or wood ashes, and one of horse droppings, the whole being mixed well together before being laid on the border. Cover this new soil with a layer 3 or 4 inches in thickness of well-decomposed stable manure, and then put on the mixture of manure and leaves to a depth of 6 inches at the point where the vines enter the house, sloping down to a depth of 24 inches in front. Thus treated there need be no apprehension of the heat imparted by the mass of fermenting materials injuriously affecting the vine roots, as the fermenting materials will simply heat the surface of the border to a depth of 3 or 4 inches. This extra heat will attract the vine roots in an upward direction and into the prepared soil and top-dressing of manure. A sufficient quantity of the fermenting dung and leaves should be kept in reserve so as to be able to add a further layer after a month or six weeks has elapsed, and this should be repeated up to the end of February or the middle of March. Early in May rather more than half of this covering should be removed from the vine border; the effect of the then increased power of the sun's rays on the border will prove beneficial to the vines. When the Grapes are quite ripe the remaining portion of the fermenting materials should be removed down to within a couple of inches of the top-dressing of short manure that was first laid.

The weight and quality of crop of Grapes resulting from vines growing in outside borders treated as described above will compensate more than fourfold for the trouble and expense incurred in doing the work. *H. W. Ward.*

LAW NOTE.

THE RAILWAY FIRES ACT, 1905.

ON January 1 of the present year there came into force an Act which to some extent redresses a grievance under which occupiers of land adjoining railways have laboured ever since the introduction of railway travelling. Until the beginning of this year such persons were unable to obtain compensation from a Railway Company for any kind of damage caused to their property by sparks escaping from engines unless they could prove that this occurred through some "negligence" on the part of the Company, a task which was practically impossible. This hardship is to some extent redressed by the Railway Fires Act, 1905, which came into force on January 1, 1908, and which in effect provides that where damage is caused to agricultural land or to agricultural crops by fire arising from sparks or cinders emitted from any locomotive engine used on a Railway the Company shall be liable to pay compensation whether the Company has been guilty of negligence or not. The Act, however, only applies to claims amounting to £100 or under, so that if damage for more than that amount is claimed the difficulty in the way of enforcing compensation from the Railway Company still remains.

It will be noticed that this Act is expressly stated to apply to agricultural land or crops "Agricultural land" for this purpose includes arable and meadow land and ground used for pastoral purposes or for *market or nursery gardens*, and for plantations, woods and orchards, and also includes any fences on such land, but it does not include any moorland or buildings.

The words "agricultural crops" include any crops on agricultural land, whether they are actually growing at the time of the fire, or whether they have already been taken up from the land, *provided* they are not already led or stacked. The term "railway" includes any light railway, and also any tramway worked by steam power.

As Railway Companies are liable to pay compensation in the above cases it has been considered only fair to give them the right to take all steps necessary for salvage as speedily as possible. Accordingly the Railway Company can enter on the land where the conflagration occurs, or on any adjoining land, and do everything reasonably necessary for the purpose of extinguishing or arresting the spread of the fire.

The Railway Company may also cut down and clear away any undergrowth and take any other reasonable precautions necessary for the purpose of preventing or diminishing the risk of fire there, but they may not cut down or injure any trees, bushes or shrubs (apart from undergrowth), without the consent of the owner.

Persons who wish to claim compensation under this Act must be careful to see that written notice of their claim is sent to the Railway Company within seven days after the damage is sustained, and also that particulars in writing of the actual damage sustained are sent to the Company within 14 days after the occurrence.

It will be seen that the relief granted by the new Act is still only partial, for not only does it limit the damage that can be claimed to £100, but its provisions do not apply at all to the case of damage to *buildings*, so that if a house is burnt down by sparks from a railway engine the owner will still be without any redress unless he is in a position to prove that the Railway Company was guilty of negligence. *H. Morgan Veitch.*

FRUIT REGISTER.

THE YELLOW-FRUITED MIRABELLE PLUM.

M.'s note, printed in the issue of the *Gardeners' Chronicle* for December 28 last, p. 452, in reference to Mirabelle Jaune Plum, has reminded me of the fact that I only know of one garden in the United Kingdom (Longford Castle) in which this Plum was, and perhaps is still, grown. It was introduced to Longford Castle gardens very many years ago from France by a French lady. There were two fan-trained trees growing respectively against walls having east and west aspects. They bore heavy crops of rather small, roundish oval, yellow-skinned fruits, which were covered with a light bloom and were suffused with small, reddish spots next the sun. The flesh was Apricot colour when fully ripe, sweet, and rich. The tree is not a robust grower. The shoots are downy, numerous, short-jointed, and weak, rather than strong, in growth. The leaves are small, ovate, slightly cordate at the base, and downy above on young shoots. At Longford the fruit was appreciated for the making of compôtes and preserves in August and September. I do not think that the Mirabelle Jaune Plum is included in any of the British nurserymen's catalogues. *H. W. Ward.*

SWAN'S EGG AND KNIGHT'S MONARCH PEARS.

YOUR correspondent *F. M.*, seeking some explanation as to the cause of Swan's Egg and Knight's Monarch Pears being so seldom cultivated is, I venture to say, answered in the last paragraph of his letter. "In cool summers in the north, even on a south wall, the fruits of this variety do not ripen in the fruit-room." My own observation confirms this; the first week in December there were about 20 pots (56 lb. each, nett) offered by auction in the Hereford fruit market. These realised 2s. 8d per pot, or 5s. 6d. per cwt. Several buyers standing round made some remarks, to the effect that their experience of the variety in question (Swan's Egg) was that it frequently rotted on their hands before ripening. At the finish of the day's sale, these pots of Pears were again put up at the request of the purchaser, the highest bid then being 1s. 11d. per pot; they were withdrawn. The week following these pots of Swan's Egg Pears were again in the market, and realised 1s. 8d. per pot, or a loss of 1s. per pot to the original buyer. Evidently buyers will not have Swan's Egg Pear unless the price is low enough to cover the risk of failure to ripen. The moral therefore is: do not plant Swan's Egg unless you have a particularly favourable situation suited to the variety. *Dawson Smith, Grosmont Place, Hereford.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

PREVENTION OF CORRUPTION ACT, 1906.—In commenting upon Sir Edward Fry's very lucid pronouncement upon this subject in your issue of the 21st ult., *Enlightened* (page 452) states—what is apparently perfectly correct—that nurserymen and gardeners seem to think that this Act was specially aimed at the gardening trade, and as a natural consequence feel aggrieved over it. That they should look upon the Act in this light is certainly an indication of their child-like innocence of what has been going on for years past in other branches of trade. Did they possess the slightest knowledge of the corruption which has been so rampant, they would, instead of miscalling the Act, bless it, and hope that it would meet with the success it deserves in assisting to purify business dealings in all branches of commerce in this country. To use a colloquial phrase, nurserymen

are "not in it" with many other tradesmen who stoop to all kinds of acts merely for the purposes of extending their businesses. While it must be admitted that some nursery firms have undoubtedly been guilty of adopting very reprehensible methods of getting orders, the majority have followed a more or less uniform system which—without examining its ethics too closely—from long custom had been regarded as a perfectly legitimate way of doing business until the passing of the Corrupt Practices Act. However much this custom of paying discount may be regarded as a seeking for favours to come, it had at least the saving grace of appearing to be an acknowledgment for favours that were past and finished with. Notwithstanding the new law, certain tradesmen entirely outside the gardening business are still not merely showing their appreciation of past favours, but deliberately making presents to interested parties before any business transactions have taken place. In this matter I am not speaking from mere hearsay, but from actual experience. At the present moment I am testing a certain material, which shall be nameless, from several different manufacturers, but up till now have not quite decided which will suit my purpose best. A few days before Christmas I received the following letter from one of the firms in London:—"Dear Sir,—At the request of our Mr. ——, we have much pleasure in advising you that we have forwarded to you some birds, which we trust you will accept, together with our best wishes for Christmas and the New Year." The same morning upon which I received this letter a brace of pheasants came to hand. A month ago this firm had not so much as heard of me, or I of them, and yet so benevolently inclined are they that they cannot let this festive season pass without trying in a small way to help me enjoy it! The birds were returned as soon as received, and a letter sent to the firm, expressing my thanks for the generous feelings which had prompted them in sending the gift, but pointing out the fact that their representative had made a very grave error in asking them to act in the manner they had. In all my dealings with nurserymen, which now goes over a period of 17 years, I have never once had occasion to suspect a single firm of trying to gain my goodwill in any other way than by supplying me with the very best stuff at the most reasonable charges. *Interested.*

———Sir Edward Fry's article under the above heading is interesting, as far as it deals with the meaning of the Act, but there are phrases which tend to make the gardener appear a bit of a scoundrel. For instance, he says the great tendency of such a gift is to tempt the gardener to neglect his duty in several ways—his duty to point out any defects in the goods supplied to his master: to give, if required, independent advice as to the seedsman to be employed; to order or advise the ordering of no more seeds or plants than the garden requires; these gifts have a tendency to make the gardener blind to the defects in the goods, to prefer the bribing seedsman over the honest one, to order or advise the ordering of more goods than are required. If Sir Edward has experienced this sort of treatment at the hands of gardeners, I am sorry for him; at the same time, I very much doubt whether a gardener interested in his profession—for such it is—would be gulled as easily as he makes out. Consider the gardener who exhibits vegetables, for instance; it would be no advantage to him to have defective seeds or anything else that is inferior, and he would certainly advise his employer to deal with the best firm. Should he need advice, as far as ordering seeds or other goods, there is nothing to prevent the employer seeing the order before it is sent and altering it should he think fit. I have presented a seed order after making it out, and been asked often to include something I had not put down. I maintain that a gardener interested in his work will and does bestow a care on seeds he has to deal with, with the intention of getting the best possible results for his labour. *E. Young.*

———At this season of the year those who can afford it give presents of money and goods to railway officials, but according to Sir Edward Fry's letter in the issue of the *Gardeners' Chronicle* for December 21, these gratuities are illegal, for they are given in order that special attention shall be given to their goods and chattels, as well as my lord or my lady's persons when they appear at the station, whilst those who cannot afford to give these bribes may struggle with their baggage and open the railway carriage door for themselves, &c. I have not been much burdened with discount or gratuities—an average of 10s. a year would cover it, and that and much more has been given as gratuities to others for small services rendered which were of as much benefit to my employer as to myself; at any rate I thought so. I am informed that counsel's opinion has been taken, and that to give and accept a Christmas or New Year's gift is not a crime, and whilst my employer gives these annual gratuities to railway company's servants, I am prepared to receive all that is offered me, and I trust donors will be more liberal in the future. I know of some gardeners whose employers have told them to get all they can, for they (the employers) would not get it. May I ask you, Mr. Editor, or Sir Edward Fry, if the prizes offered by seedsmen for vegetables at shows grown from seeds supplied by them are bribes? *Clean Bill.*

——— I have read the article in your issue of December 21 by Sir Edward Fry. The thing that particularly sticks in my throat is the implication—several times repeated—that gardeners are in the habit of ordering more seeds or plants than are necessary for the gardens under their charge, in order to get a larger discount. If I give my own experiences with regard to this matter, it will no doubt be typical of that of the main body of present-day gardeners. In my first place, where two members of the family were keen lovers of their garden, I obtained my seeds from which firm I chose, but neither then nor since have I been able to spend money in the free-and-easy way suggested by Sir Edward Fry, nor have I met anyone who has. In the second place, my employer also took a great interest in his garden, and was besides a shareholder in two stores where garden seeds were sold. He handed me the catalogues of both, with the remark that he would like me to try a few seeds from one of them. I was quite ready to do so, and finally divided my order between the two of them and the cheaper of the seedsmen with whom I had previously dealt, although, be it noted, I was aware of the fact that there would be no bribe from either of the said stores. I have invariably spent my evenings, for over a week each year, studying several different lists and trying my best to keep the accounts down, for my own credit, instead of, as Sir Edward suggests, ordering unnecessary seeds to obtain larger discounts. The said discount from firms of repute has, I believe, been 1s. per pound, and to hint that any gardener worthy of the name is, or has been, in the habit of ordering enough extra seeds, &c., to make the extra discount worth having, is both absurd and ridiculous. I was rather amused at Sir Edward Fry's concern as to whether his gardener neglected some part of his duties to give extra care to the bribers' seeds. Surely the remedy for this is too simple and obvious to require pointing out. Let me assure Sir Edward Fry that in these modern times, when nearly every employer or some member of his family takes an intelligent interest in their gardens, the gardener has to take special care of anything he is requested to, no matter from where it has come, or make way for someone who will do so. We gardeners are generally much more interested in having something good for our employers, their visitors, and our own gardening friends to look at, to worry ourselves much about any paltry discount, and I cannot see that the withholding of the same has made any difference in the prices charged to our employers. *Outsider.*

——— I don't think any gardener would bestow more care on one nurseryman's seeds than those of another; he has to grow them to his own satisfaction and to supply his employer with vegetables and flowers. Some employers are never satisfied and don't know how to treat their servants properly, while some help and encourage them. There are people who seem to think there is only one side to a hedge. It is a pleasure for servants to live with good and kind employers. Some of these like their servants to have bonuses, knowing they are not robbing them. The employer pays the same price now for things as he did before the Act was passed, so where is the difference, and how does it come about that anyone should imagine that they have got to pay more for things if their gardeners, keepers, and stewards receive discounts? No gardener or farmer is going to sow inferior seeds if he knows it, and it would be absurd for him to order seeds or plants that are not wanted, but it would be just as absurd if his employer were to refuse what is requisite. In any profession in the world is there anybody who knows better what is really wanted than the man who has been brought up in it? How can engineer tell shop walker, or clerk tell carpenter, butler tell gardener, or coachman tell electrician what to do? But some know everything or nothing properly. *Trusted and Interested.*

VEGETABLE TRIALS AT WISLEY.—Now that the Royal Horticultural Society has brought the gardens at Wisley to a proper condition for successfully cultivating green crops, much valuable information might be obtained in the selection of the best varieties of vegetables suitable for every purpose. Formerly these trials, although conducted with great care, have not been so completely satisfactory as could be wished. Take, for instance, the trials of culinary Peas. Various seedsmen send many varieties; they are duly numbered and entered in the trial book. In April a fine day is selected for sowing them, this date is recorded, a note is taken of the opening of the first flowers, and of the date of their being fit to gather. A sub-committee of experts is appointed to examine and report on 100 or more varieties. In discharging their arduous duties these gentlemen usually describe the cropping qualities of each variety as light, medium, heavy, abundant, or prodigious—terms more or less vague. To some extent the same remark may be applied to their opinions about flavour. From the very nature of things it is impossible for this sub-committee to see all the varieties at their best in one day. Surely it would be better if the earliest varieties were got together and sown, say, early in February, or as soon as the ground is in a favourable condition. The hardiness or fitness to stand cold spring winds would then be thoroughly tested. The dwarf kinds should be grown together and the round seeded by themselves. The Maincrop Marrowfats might very well be sown in April and the so-called late varieties in May, giving all a fair chance of being seen and reported upon at their best. Instead of describing the cropping qualities as light, medium, or heavy it would be more accurate if on, say, 6 feet of each row all the pods were gathered when at their best, and carefully weighed at the same time, noting the length of haulm and distance allowed from row to row. It would add to the interest of these trials if the senders would fully describe on the packets of their samples the height of growth, season of fitness for use, &c. The same remarks are applicable to the trials of other kinds of vegetables such as Cabbages, Cauliflowers, Carrots, Turnips, Potatos, &c. The early varieties ought to be all grown by themselves, and examined in their season of perfection. *J. McI.*

THE TERM "HERBACEOUS" (see p. 438, vol. xliii.).—What is the correct or botanical meaning of this term? It is well, in the face of recent discussion, to have it authoritatively settled. When last year the term was applied by me in a report solely to those plants which have perennial roots but purely annual stems, I was taken to task by an esteemed botanist for not being correct. The term, he said, applied to all plants having soft or herb-like stems, yet with perennial roots. Thus he would include in the term "Herbaceous" Pansies, Pinks, Carnations, Penstemons, and many other similar plants that are evergreen yet not woody or shrubby. The term admittedly has always in ordinary acceptance been applied to the section of hardy plants first named. In Johnson's *Gardeners' Dictionary* the description is: "Those perennials which lose their stems annually whilst the roots continue alive in the earth." That seems to be a practical description. Still, if it be incorrect, by botanical means let us have it determined by the highest authority once and for all. *A. D.*

THE FLORIST'S ART.—While agreeing with most of what *F. M.* says on p. 439, I cannot help but think that he would defeat the end he has in view by inaugurating shows for exhibiting the different classes of florists' work of "art" without first making a most drastic change in the way that schedules are at present drawn up and the way prizes are awarded by the judges. First and foremost, I would place dinner-tables. The methods of arrangement that one sees at shows answers no doubt to what is required by the schedule, but what gardener would dare to put the same arrangement upon the table of his employer? I think schedules should ask for a table arranged and decorated for dinner, instead of (as at present) a decorated dinner-table with a space limit. The decorations that one sees are generally arranged either too high above the table, with nothing beneath, or vice versâ. Another fault is that most competitors cover the whole space allotted to them without leaving the spaces required for such necessaries to a dinner-table as candlesticks, dessert dishes, &c. I would suggest that there should be a prize offered for the best-decorated dinner-table, laid as for dinner, to be judged (first) for general effect as would be seen upon entering the room, (second) the arrangement of flowers, lightness, etc., (third) the effect obtained when seated at the table. The effect obtained from this view should have great bearing upon the awarding of the prizes, as the guests that are to dine have to be in a sitting position for a period varying from one to two hours. The effect from this view should be a soft, light maze of flowers and foliage, but arranged in such a manner as not to obstruct the view or to hinder conversation across the table. Further, these tables should be judged for colour by the daylight effect only (at shows, of course), or else ask especially for a colour suitable for view in artificial light. Groups should be asked for in distinct colours, or arranged for a certain purpose, viz., for drawing-room, conservatory, or winter-garden. Tables of pot plants should be shown as they would be arranged for stages in the conservatory. Gardeners as a class have taste; if not, I say they have no right to be gardeners. I do think they need opportunities to study effect at shows, as for the most part they are rather given to copying too much. They need to be more original in their designs. Let the committees of societies change the wording of their schedules, give competitors a free hand to exercise their taste and discretion, and we shall hear less of lack of taste and of the monotony of horticultural exhibitions. *Geo. W. Young, Rampton Manor, Lincoln.*

——In *F. M.'s* interesting note on the arrangement of cut flowers printed in the *Gardeners' Chronicle* for December 21, p. 439, mention is made of the lack of good taste that is often displayed by gardeners, &c., in the arranging of cut flowers for effect, and, with a view to effecting an improvement in this direction, suggests that important and influential horticultural societies should offer cash prizes, &c., for various kinds of floral arrangements. This is a good suggestion on the part of *F. M.* However, I may be permitted to state that the Shropshire Horticultural Society has for several years past offered such prizes, and the exhibits annually staged in competition for the Society's liberal prizes are most artistically arranged, and afford educational hints and examples of the florist's art to the numerous professional and amateur horticulturists and other visitors who attend the Shrewsbury shows in their thousands, and make mental notes of what they see, subsequently turning them to good account. Referring to the Shropshire Horticultural Society's schedule of prizes for the August show of 1907, I find that in 15 classes for its many kinds of floral arrangements the Society offered £75. Two of the 15 classes are for the arrangement of cut flowers only for dinner-table. And, again, in addition to the above-mentioned number of classes, prizes to the value of £9 15s. are offered in the three classes provided for collections of fruit, which collections, it is stipulated, must be decorated with flowering or foliage plants (in pots not exceeding 5 inches in diameter), also cut flowers or foliage in glass or ware are allowed, at the exhibitor's discretion; the floral decorations of the said collections being judged separately, are awarded prizes independently of the merits of the individual collections of fruit, for which prizes totalling £89 are offered. Thus, it will be seen that £84 10s. is offered in 18 classes for floral arrangements, personal and household adornment. *H. W. W.*

——*F. M.*, on p. 439, wrote rather lightly of the efforts of gardeners as decorators. Were not the groups of plants exhibited at the last great Shrewsbury show arranged with skill—the result produced by the individual exhibitors excellent? These exhibits were surely something to be proud of, and were not merely arranged to "occupy the floor." That many unsuccessful attempts are made by exhibitors at the various exhibitions throughout the country is true. These failures are, however, not confined to the decorator, but may be witnessed in other classes throughout the exhibitions. Respecting the decorations of the dinner-table and the apartments in a private house, the wishes and taste of the employer must be studied in the first instance. Tastes differ as to what may, or may not, constitute a good table decoration. *C. R., Herts.*

——I quite agree with *F. M.* (p. 439, December 21) that good material is often wasted through want of taste in using it. The great mistake that is usually made is that too much variety is crowded together. We often see this at the Royal Horticultural Society's meetings. Yet we also see some neat and well-arranged exhibits. The late Mr. John Wills set a good example when he started the fashion of grouping special subjects together, and relieving with a good groundwork of green and a background of tall, feathery Palms and other foliage; yet very few who attempt to imitate him produce as good an effect. I have been privileged to see some of the work done by the leading florists, and there is usually some decided feature which strikes the eye as artistic, being very different from the ordinary flower-show groups or arrangements. Gardeners as a rule have little practice in the decorative art, and when they do have a special arrangement to carry out, they usually have but little time to do it in. I believe that there are many gardeners who have good taste and would be able to display it if they only had more practice and the requisite time to carry out the work properly. At flower shows one never knows what the judges' opinions may be, and when the first prize usually goes to similar arrangements as those seen for at least the past 30 years, and any new or novel design is passed, it does not encourage exhibitors to introduce novelty. With cut flowers it is different: we see great alterations; but when a gardener, who has rather stiff fingers, attempts to make up a bouquet for some special occasion, he is at a disadvantage compared with a florist or his assistants, who are always in practice. The worst exhibits that I have noted in competitions during last season have been the so-called shower-bouquets. It is surprising that the Royal Horticultural Society do not give a little more encouragement to exhibitors of floral arrangements. If one of the annexes in the hall could occasionally be devoted to the purpose, it would be of interest to most of those who attend the meetings. *A. H.*

APPROACHING MARRIAGE OF MR. W. M. TREVOR LAWRENCE.—The public announcement of the marriage next month of the eldest son of the President of the Royal Horticultural Society, Sir Trevor Lawrence, Bart., V.M.H., with the youngest daughter of the late Brigadier-General Eyre Crabbe, C.B., a distinguished officer of the Guards, and formerly a near neighbour to Burford Lodge, recalls the interesting coincidence that the grandmothers of both of the young people were in their days amongst the best known exhibitors of plants. The name of Mrs. Lawrence, of Ealing Park, can never be omitted in any history of the progress of horticulture in England, and her exhibits at the once famous and popular, as well as fashionable, flower shows in the old Chiswick Gardens, remain deeply impressed on the minds of all old enough to remember them. Though doubtless then little dreamt of, how very fitting has it been that her son, so ardent an horticulturist also, should become not merely a President of the Royal Horticultural Society, but especially the President, under whose control the society has risen to its present great height of prosperity and popularity. The other lady was, a Mrs. Spooner, an equally enthusiastic plant grower and exhibitor in the forties of the past century at the shows of the old Southampton and Winchester Horticultural Societies. At that day, Mrs. Spooner's chief competitors—for flower shows in those days mostly comprised pot plants, and very limited then as compared with to-day was the range of selection for such purposes—were the Rev. Canon Beadon, of North Stoneham Rectory, the Rev. Mr. Rashleigh, of Bursledon, and the Rev. the Warden of Winchester College. In my youthful days I knew Mrs. Spooner, as she very often paid visits to the Hill Nursery of Bridgewater, Page & Son, near Southampton, where my father was foreman, and later in life when she married Colonel Eyre Crabbe, a gentleman of high position in the town, they jointly built that beautiful suburban residence, Glen Eyre, Bassett, situate in a once wild dell. This, under Mrs. Crabbe's instructions, aided as she was by her faithful gardener, Mr. Stewart, who still lives on the place, a nonogenarian, became a really beautiful garden, in which, perhaps, more freely than in any other such garden in the kingdom, Camellias grew and flourished in the open as single shrubs in beds and on walls, with great luxuriance and beauty. A devoted gardener was Mrs. Crabbe, and one never tired of talking about the art or of describing the charms of her gardens. The late Brigadier-General Crabbe was her only son of that name. He chose a military career, and before his early death had risen to a distinguished position in the British Army. *D.*

VARIETY OF PEA.—I had a Pea growing on the side of a Celery trench, and it looked like a Sweet Pea when it was in bloom. The flowers were blue, with light-blue wings, but when the seed pods formed they were larger than those of American Wonder. Could any reader tell me if he has had any Peas like it? The Peas have a nice flavour, and the seeds are quite distinct, having a small streak on them. I showed the plants to several gardeners and they told me they had not seen one like it before. *J. Sheehan.* [You should have sent some for our inspection.—ED.]

JUDGING VEGETABLES AT EXHIBITIONS.—There is nothing in the present system of vegetable judging at shows to deter young growers from competing, except it be the young grower who thinks he knows better than experienced judges and therefore grumbles when his exhibits do not win prizes. It does not matter also whether vegetables in collections are judged by points or without pointing. If the judges be capable men, it is the best that will win. When show committees require that collections be judged by points, and fix the scale of points for each dish or kind, the judges have to do as instructed. When such is the case, the points are published on the respective collections. Nothing exhibited in the show arouses such interest as does the reading of these lists, and they become subjects of discussion and criticism. How points as maximums should be granted to various kinds of vegetables may be subject to criticism, but once settled by show committees, they remain for the time being, laws to both judges and competitors. *D.*

THE HEATING OF GLASSHOUSES.—As a practical grower I thoroughly endorse Mr. Alexander's statements (see p. 5) as regards the heating of Orchid houses. What a lot of worry and arguments it would save growers if only they were all in the happy position of Mr. Alexander and had sufficient boiler power! The old theory of calculating the pipe heating surface is laughed at by present-day engineers. To have what Orchid growers require—that is, heat without hot, dry, pipe heat—one must have more boiler power than is generally provided. A test in the up-to-date method is: take the pipe surface heat at a point of about 3 or 4 yards away from the boiler. If the return pipe surface heat is about 30 or 40 degrees Fahr. below the flow pipe surface heat, then you can rest assured your boiler is sufficient, but if there is any greater difference between the flow and return heat, then there is too much piping for the boiler to properly heat. The expert figures are as follow:—Flow surface heat at the said distance, 160° Fahr.; return, 120° to 130° Fahr. Growers have had a good time during this spell of cold weather to test the power of their boilers

thoroughly. Most of our leading trade firms and private growers find it more beneficial and far more economical to have slightly more boiler power than is required. Happy is the grower who can rely on his power to maintain steady temperatures! *J. Pitman, manager to S. Edgar & Co., Orchid Growers, South Woodford.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

DECEMBER 31.—*Present:* Mr. A. E. Bowles, M.A., F.L.S., F.E.S. (in the chair); Messrs. A. Worsley, C. H. Hooper, J. W. Odell, and F. J. Chittenden, hon. secretary.

Cankered (?) Rose roots.—A report was received from Mr. GUSSOW concerning the Rose roots shown at the last meeting by Mr. JENKINS, as follows: "I find the trouble with the Rose roots is not canker, and cannot be transferred from one plant to another. It is generally accepted that canker is caused (a) by frost; (b) by fungus; (c) by any other mechanical injury which fungi have infested. In the present case there is no fungus present, and if the root in the attacked plant (when repotting) is cut away, no injury will be done to the plant. The growth is nothing but a continuous formation of adventitious roots, especially where the root is bent or injured. New callus is formed, and from that callus rootlets are everywhere sent out, but as the plant depends on the root system of the Manetti no use is made of these roots, and they develop but little.

Grease bands and winter moth.—Messrs. W. Voss & Co., of Millwall, showed specimens of grease bands taken from trees on Mr. Michell's fruit farm, Enfield Highway, covered with both male and female specimens of winter moth (cheimatobia brumata). The bands had been placed on the trees in the middle of November, and no other insects but these had been caught with the exception of two or three weevils. The chairman remarked that the time of appearance of this moth varied greatly with the seasons, frequently being found as early as the beginning of October. Grease banding to be thoroughly efficient should be commenced then, and the bands should be kept sticky until near the end of March in order to capture other species of a similar nature.

Seed and soil inoculation.—Mr. CHITTENDEN gave some account of his experiments with seed and soil inoculation of leguminous crops.

Double Anemone blanda.—Rev. Canon ELLACOMBE sent buds of this beautiful form, which has occurred in his garden, remarking that it is the first Anemone to show buds this season.

LINNEAN SOCIETY.

DECEMBER 19.—A general meeting was held on the above date, Prof. W. A. Herdman, F.R.S. (President), in the chair. Dr. G. Archdall Reid read his paper, communicated by Sir Ray Lankester, K.C.B., F.R.S., F.L.S. "On Mendelism and Sex," of which the following is an abstract:—

Species are adaptional forms which have arisen under the operation of Natural Selection. The evidence is plain that, speaking generally, variability is controlled and regulated by Natural Selection; therefore variability itself is, in a real sense, an adaptation. Nearly all variations are spontaneous, as is proved by a mass of evidence afforded by human beings: Natural Selection builds solely on spontaneous variations. When selection ceases as regards any character, that character tends to retrogress; therefore retrogressive variations tend to predominate over progressive variations. This tendency to retrogression is very useful, and has played an immense part in adapting species to their environments. The author then touched upon blended and alternative inheritance; fluctuations and mutations; differences between Artificial and Natural Selection; and differences in the mode of reproduction of sexual and unsexual characters. The mode of reproduction of mutation tends to resemble that of sexual characters; when conjugation occurs there is an appearance of alternative inheritance as regards both sexual characters and mutations, but it is an appearance only. The evidence is plain that there is only alternative reproduction combined with latency of one alternative and patency of the other, and actual blending between the patent character of one individual and the latent character of the other, therefore blending is universal. This tendency owing to the predominance and prepotency of retrogressive characters tends to cause retrogression on cessation of selections, and this is the function of sex.

The next General Meeting will be held on Thursday, January 16, at 8 p.m.

PAPERS.

1. Mr. Arthur W. Sutton, F.L.S.—Brassica crosses, illustrated by lantern-slides.

2. The same.—Notes on Wild Types of Tuber-bearing Solanums, illustrated by lantern-slides.

3. Mr. S. T. Dunn, F.L.S.—Revision of the genus Illigera, Blume.

4. Mr. Bunzo Hayata.—New Coniferæ of Formosa.

EXHIBITION.

Mr. A. P. Young, F.L.S.—Lantern-slides showing stages of soil-denudation consequent upon removal of forests.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

DECEMBER 19.—*Committee present:* Messrs. E. Ashworth, R. Ashworth, C. Parker, A. Warburton, H. H. Smith, P. Smith, Z. A. Ward, F. Sander, A. J. Keeling, J. Walmsley, E. Shill, J. Cypher, F. Ashton, P. Weathers (hon. sec.).

Fifteen good groups of plants were shown at this meeting, which was undoubtedly the best ever held by the society.

H. J. BROMILOW, Esq., Rainhill (gr. Mr. Morgan), staged a charming group of Cypripediums, all the plants were beautifully fresh and well grown. Cypripedium × Thalia var. "Mrs. Francis Wellesley" was awarded a First Class Certificate—it is a beautiful hybrid; C. × Thalia var. gigantea received a similar award; C. × Hitchensiæ var. Eva, C. × Mons. de Curte (Rann Lea variety), C. × Archimedes (Rann Lea variety), C. × Rita, C. × Evelyn, and C. × Actæus var. Cecil, received Awards of Merit. A Silver-gilt Medal was awarded to the group.

Z. A. WARD, Esq., Northenden (gr. Mr. Weatherby), made a nice display of some well-grown Odontoglossums, Lælio-Cattleyas, &c., which relieved somewhat the sameness of the numerous Cypripedium groups. Odontoglossum crispum "Rose Queen," O. × amabile var. Queen of Spain, and O. × Jasper (O. × amabile × O. crispum) were voted Awards of Merit. A Silver Medal was awarded to the group.

Messrs. CYPHER & SONS, Cheltenham, received a Bronze Medal for a small, but interesting group of plants, chiefly varieties and hybrids of Cypripedium.

J. LEEMANN, Esq., Heaton Mersey (gr. Mr. Smith), gained a Silver Medal for a miscellaneous group of plants, some good Odontoglossums, hybrid Lælias and Cypripediums being noticed. Cypripedium insigne var. Apollo was given an Award of Merit.

Messrs. KEELING & SONS, Westgate Hill, Bradford, was awarded a Bronze Medal for a good group.

J. H. CRAVEN, Esq., Keighley (gr. Mr. Corney), obtained a Silver Medal for a group of Cypripediums. Awards of Merit were given to Cypripedium insigne giganteum, Heaton variety, C. × Evelyn Ames, Craven's variety, and C. × Cravenianum: a First-Class Certificate was awarded to C. × Archimedes, "Craven's variety."

Mr. W. BOLTON, Orchid grower, Warrington, made a magnificent display with 25 beautiful specimens of Cypripedium insigne var. Sanderæ, each plant carrying 8 or 10 flowers. (Silver Medal.)

Messrs. H. LOW & Co., Enfield, staged a good group, in which were Cattleyas, various hybrids, and some good Cypripediums. (Silver Medal.)

Messrs. SANDER & SONS, St. Albans, sent an interesting group of Cypripediums.

G. SHORLAND BALL, Esq., Burton, Westmoreland (gr. to Mr. Herdman), staged an extensive group of Cypripediums. C. × beechense var. superbum, a good form, was awarded a First Class Certificate. Awards of Merit were voted to C. Prospero var. majus, C. × Leeanum var. Balla, C. × Herdmani, C. × Thomas Mills, and C. × Hera var. Madelinei. A Silver Medal was awarded for the group.

Mr. J. ROBSON, Altrincham, received an Award of Merit for Cypripedium × Hitchensiæ var. magnificum. He also exhibited Odontoglossum crispum var. Mrs. A. Warburton.

A. WARBURTON, Esq., Haslingden (gr. Mr. Dalgleish), staged a very fine group of Cypripediums in the "Sander Cup" competition. In addition to confirming a large number of previous awards the following new ones were given:—Awards of Merit to C. × Actæus, Warburton's var., C. × Hitchensiæ var. Baroness, C. × Adam, C. × Marjorie var., C. insigne alba var. Warburtonianum, C. × Bertie, C. × Harold, C. insigne var. "Etendard." (Silver-Gilt Medal for group.)

S. GRATRIX, Esq., Whalley Range (gr. Mr. Shill), received a First-Class Certificate for Cypripedium × Fulshawense, West Point variety, and an Award of Merit for C. × Annie Carter.

Mr. W. SHACKLETON, Bradford, received an Award of Merit for Odontoglossum crispum var. Mont Blanc, a fine white variety.

J. MACARTNEY, Esq., Bolton (gr. Mr. Holmes), received a Silver Medal for a miscellaneous group, and a Bronze Medal for Cypripediums. Lælia anceps Amesiana, Temple's variety, and Cypripedium × Mons. de Curte, Hey House variety, received Awards of Merit.

E. ROGERSON, Esq., Didsbury (gr. Mr. Price), received Awards of Merit for Lælio-Cattleya × The Hon. Mrs. Astor and Cypripedium × William Hughes.

Mr. C. PARKER, Preston, received an Award of Merit for Cypripedium × Fernbankense, a pretty hybrid.

Messrs. HEATH & SON, Cheltenham, were awarded a Silver Medal for a good group of Cypripediums. *P. H.*

BRITISH GARDENERS' ASSOCIATION.

DECEMBER 31.—At the meeting of the executive council on the above date, nine new members were elected, making 1,128 since the establishment of the association. The Secretary reported that the last issue of the *B.G.A. Journal* had been posted to every member both at home and abroad. The design for members' certificate was adopted, and it is hoped it will be ready for issue in a few weeks. The report of the Richmond and District branch for the past year was received, and will be printed in the next issue of the *Journal*. Gardeners are reminded that the B.G.A. is confined to qualified gardeners only, and that new members may join at any time, provided their credentials are up to the required standard. Forms can be obtained from the Secretary, B.G.A., Talbot Villa, Isleworth, W. *J. H.*

Obituary.

ARNOLD MOSS.—We regret to hear of the death on January 1 of Mr. Arnold Moss, head of the firm of Messrs. Jacob Wrench & Sons until the business was sold in 1905. Since that time the late Mr. Moss and his son, Mr. E. M. Moss, have traded as A. & E. Moss at 46, King William Street, London. Deceased, who was 63 years of age, will be remembered by many of our readers as having helped the gardening charities on every possible opportunity. He was a frequent speaker at the festival dinners of both the Gardeners' Royal Benevolent Institution and Royal Gardeners' Orphan Fund.

GARDENING APPOINTMENTS.

Correspondents are requested to write the names of persons and places as legibly as possible. No charge is made for these announcements, but if a small contribution is sent, to be placed in an envelope bearing the words "Gardeners' Orphan Fund," it will be thankfully received, and an acknowledgment made in these columns.]

Mr. GEO. D. LILLEY, previously Gardener to the late Lady GEORGIANA SHAKERLEY, at Moreton Hall, Congleton, Cheshire, and recently with Messrs. DOBBIE & Co., Ltd., as Gardener to Mrs. PARR-YATES, Ince Blundell Hall.

Mr. C. GILES, late Gardener to E. A. HOSKYNS, Esq., Norton House, Lacock, Wilts, as Gardener to G. LEIGHTHURST, Esq., Latimer Road, Headington, Oxford.

Mr. A. W. TAYLOR, for the past 5½ years Foreman at St. Audries, Bridgwater, as Gardener to Sir WALTER J. TREVELYAN, at Nettlecombe Court, Taunton.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending January 8.

A very sudden change in the temperature.—The recent cold period lasted from December 26 until January 6, or for 12 days. During the greater part of that time the day temperatures were about as low as would be seasonable in the coldest part of the night. Only the last four nights were in any way exceptionally cold, but on the coldest of these the exposed thermometer registered 25° of frost. A remarkably sudden change in temperature then took place. For instance, the lowest reading in the thermometer screen on the night of the 5th was 15°, and in the warmest part of the following day the temperature was 49°—a difference of 34°—the greatest range in temperature in any one day that I have yet recorded here in January. Owing to the absence of snow at the time, the temperature of the ground fell to 37° at 2 feet deep, and to 34° at 1 foot deep. After a dry period lasting a fortnight there occurred during the night of the 7th inst. an exceptionally heavy fall of rain and snow. The aggregate depth of this fall (including rain and melted snow) was 1¼ inch, which is the heaviest fall in any night or day since June, 1906. On the morning of the 8th the ground was covered with snow to the average depth of 2½ inches. This is the first time the ground has been completely covered with snow this winter. The sun shone on an average for 2 hours 47 minutes a day, which is nearly twice the average duration at this period of the year. The winds were, as a rule, moderately high, and for the first five days came from some point between north and east. The mean amount of moisture in the air at 3 p.m. fell short of a seasonable quantity for that hour by as much as eight per cent. The last Rose bloom of the year was destroyed by frost on the 5th, which is 23 days later than the average date of its destruction in the previous 22 years, and 10 days later than last year.

MONTH OF DECEMBER.

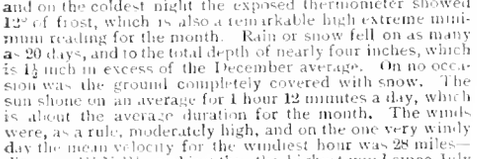
Remarkably warm and very wet.—This was the warmest December for seven years. In fact, during the first 25 days there did not occur a single cold day and only a few cold nights. The highest temperature registered in the thermometer screen was 56°, the highest in December for 19 years, and on the coldest night the exposed thermometer showed 12° of frost, which is also a remarkable high extreme minimum reading for the month. Rain or snow fell on as many as 20 days, and to the total depth of nearly four inches, which is 1½ inch in excess of the December average. On no occasion was the ground completely covered with snow. The sun shone on an average for 1 hour 12 minutes a day, which is about the average duration for the month. The winds were, as a rule, moderately high, and on the one very windy day the mean velocity for the windiest hour was 28 miles—direction W.N.W., making this the highest wind since July 1901, or for seven years. The average amount of moisture in the air at 3 o'clock in the afternoon was 2 per cent. below a seasonable quantity for that hour.

THE YEAR, 1907.

Rather cold and dry with an average amount of sunshine. The mean temperature of the past year was slightly below the average for the previous 22 years. The last four months of the year were all moderately warm, but in the previous eight months there occurred only one unusually warm month, and that was March. On no occasion did the temperature in the thermometer screen rise above 78°—making this the lowest extreme maximum since 1890, or for 17 years. The lowest reading registered by the thermometer exposed on the lawn was 14°, which is the highest extreme minimum temperature since 1898, or for nine years. The total rainfall fell short of the average for the previous 51 years by ¾ inch. The only months in which the fall of rain exceeded the average were April, May, October, and December. Taking the year as a whole there was an average record of sunshine. The sunniest months of the year were March and September, these being brighter than any of the summer months.

OUR UNDERGROUND WATER SUPPLY.

The total rainfall for the last three months has exceeded the average for the same period in the previous 51 years by 2¾ inches, which is equivalent to an excess of 61,300 gallons on each acre in this district. Last year at the same time there was an excess of 90,430 gallons per acre. *E. M., Berkhamsted, January 8, 1908.*



ADDRESS: *J. N.* The correct address is Royal Horticultural Hall, Vincent Square, Westminster, London, S.W.

APHIDES: *F. W. J.* We cannot recommend any better insecticides for use against the "Snowy fly" or "White fly of Tomatos" than vaporising with a nicotine preparation, or fumigating with hydrocyanic acid gas.

BOTANIC GARDENS: *S., Thirlhall.* If you refer in your letter to the Royal Botanic Gardens at Kew it will not be possible for you to obtain employment there until you have acquired more experience. You had better get a place in a good private garden, and when approaching 20 years of age apply to the Curator, Royal Gardens, Kew, for a form of application for employment.

COUNTRY GENTLEMEN'S ASSOCIATION: *Enquirer.* Apply to the secretary of this association at 21 & 25, St James Street, London, S.W.

GARDENER'S NOTICE: *W. E. B.* It is customary for head gardeners to receive one month's notice before terminating employment.—*A. J.* It is doubtful if you could successfully claim more than a week's notice, assuming you have no agreement on this matter.

GAS LIME: *W. T. G.* (1) The best time to apply gas lime is in the autumn or early winter, so that it may get well incorporated with the soil before the time for sowing crops in the spring. Two tons per acre may with safety be applied. Gas lime should always be exposed to the air for about a month before digging in, in order that the sulphuretted hydrogen gas may escape, as this gas is injurious to plant life. The action of the air on the gas lime is to convert the original substance into sulphate of lime (gypsum). (2) Light soils are generally deficient in organic matter or humus, consequently there is but little material for the gas lime to work upon. Gas lime, like ordinary quick lime, combines with substances already in the soil and renders them soluble and useable by plants. Lime is not a plant-food in itself, yet it is a most important element of plant-food, because it converts the insoluble and otherwise unusable food into an assimilable form that crops can take up. (3) Ordinary quick lime or ground burnt lime acts in the same way as gas lime; they all tend to check the acidity of the soil; they assist in forming soluble phosphates and nitrates; they encourage a low, compact growth and increased fruitfulness in plants.

MANURE FOR SWEET PEAS: *Amersham.* (1) A manure to be recommended for Sweet Peas is one consisting of three parts of super-phosphate and two parts of bone meal mixed together, sown at the rate of 6 ozs. per square yard, and dug in a month previous to sowing the seed. If the soil is poor in humus matter, a small dressing of good stable manure may be dug in previous to the application of the artificials. The dung should be dug in deeply. (2) Horse-hoof clippings are a valuable source of nitrogen, as they contain from 14 to 15 per cent. of that element. When added to the soil, they very gradually decompose, and thus form a slowly acting and lasting manure. They are extremely useful for digging into a vine border; they can with advantage be used in potting up Pelargoniums, Carnations, Chrysanthemums, Tomatos, &c. Use about half-a-pound of the clippings to 1 cwt. of soil.

LINNEAN SOCIETY *J. L.* If you wish to become a Fellow of this Society, you should address an application for particulars to the Secretary, Burlington House, Piccadilly, London, W.

MEALY BUG ON VINES: *E. G. R. & A. H.* After scraping off the loose bark that would afford hiding places for this or any other pest, the canes may be dressed with the following mixture. Take one part coal tar and six parts clay; dry the clay and powder it so that it may be passed through a ¼ in sieve. Work the tar and clay thoroughly together, adding sufficient boiling water to make the mixture of the consistency of paint. The "paint" should be smeared over the canes, filling all the crevices, but avoiding coating the buds themselves. Keep the mixture well stirred during the entire process of application. Another and stronger dressing, which is not recommended for use on the same plants year after year, is that known as the caustic wash, which is composed as follows: Caustic soda (70 per cent.), 1 lb.; potassium carbonate (80 per cent.), 1 lb; soft soap, 10 ozs.; water, 10 gallons. The soda and potash should be dissolved in water, and the soap, having previously been dissolved in hot water, added to the solution, afterwards making up the quantity to 10 gallons. The dressing recommended by Mr. Coomber in his Calendar on "Fruits under Glass," on p. 7 in the last issue, may also be safely applied for the extermination of mealy bug. You should read the weekly Calendars regularly.

NARCISSUS NEAR PINE TREES: *J. Moore.* Whether or not Narcissus will prove permanently successful "in grass or borders on which the needles of Pine trees are constantly falling" will largely depend upon the number of the trees and the amount or density of the shade imparted by them. The bulbs will also be affected by the dryness or wetness of the soil in which they are growing. Generally, however, where the soil is favourable to the development of the bulbs, and sufficient air and light reaches the plants during their season of growth, the bulbs succeed well. Instances occur to us where the bulbs planted years ago in "rides" and "drives" through a wood, many acres of which are of the Corsican Pine, are eminently successful, and they grow well and flower freely. In such circumstances the soil should be moist clay. It is another matter altogether where the bulbs have been planted near to large trees growing in light and over-drained soil. If your soil is cool in summer, and of good depth, you have not much to fear. The growth and flowering of the plants in the coming spring will be your best guide. You give us no idea of the length of time the bulbs have been planted or what measure of success has in the past been attained.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

FRUITS: *Warner.* Apple Malster.—*W. E. W.* Apple White Westling.

PLANTS: *J. E.* 1, Pteris cretica cristata; 2, P. serrulata; 3, Davallia Mooreana.—*L. G. P.* Ornithogalum lacteum. It is quite possible that it came from South Africa in the manner you describe.—*E. C.* Ornithogalum lacteum.—*A. T.* 1, Oncidium barbatum; 2, Oncidium pubes; 3, Stelis micrantha; 4, Ada aurantiaca; 5, Odontoglossum Lindleyanum; 6, Odontoglossum Adrianæ.—*R. S. H.* 1, Pteris tremula; 2, Pteris hastata; 3, Selaginella Wildenovii; 4, Helxine Solierolii.

SULPHATE: *W. F.* Chemicals used in photography are as a rule not to be recommended as plant-foods as some of them are decidedly injurious, the exception being in the case of ammonium chloride which contains the same amount of nitrogen as ammonium sulphate, namely, 21½ per cent., but the cost of ammonium chloride prevents it being used as manure. The price is from 20s. to 24s. per cwt wholesale. We cannot recommend particular firms who are wholesale sellers of manures. The present wholesale price of nitrate of soda is 11s. 6d per cwt; basic slag 3s. per cwt.; ground lime 1s. 6d. per cwt. Sulphate of soda is not to be recommended as a manure for general use, most soils contain sufficient of this element. Sulphate of potash is much to be preferred, the cost is 10s. per cwt. Manurial applications suitable to heavy soils will depend upon the crops to be grown. For flowering plants, superphosphate, basic slag, lime and bone-meal from 3 to 5 cwts. per acre of either may be used, to be dug in during winter or early spring. For vegetables, superphosphate 4 cwt., and ground lime 1 cwt. per acre, mixed together and dug in before planting, or 6 cwt. basic slag may be used. Nitrate of soda 2 cwts. per acre may be sown when the crops are able to take it up, about March. For lawns on heavy soil use superphosphate 3 cwt. and ground lime 1 cwt per acre, to be sown in early spring, and 1 cwt sulphate of ammonia per acre in March. Basic slag encourages too much white clover to make it valuable for lawns. 4 cwts. of manure per acre is equivalent to 2¾ lb. per square rod or perch and 1½ oz. per square yard.

SPARTINA TOWNSENDII.

GIVING evidence some time ago before the Royal Commission on Land Erosion, Lord Montagu of Beaulieu called attention to the rapid spreading of a grass on the mudbanks of the Hampshire coast. According to him, it was accidentally introduced from the Argentine not many years ago and locally known as Rice Grass or Sea Rice. It was a rapid grower, overrunning mudbanks which had been hitherto bare and exposed, solidifying and raising them. The area covered by the grass was estimated at 6,000 to 8,000 acres. The matter was submitted to the Director of the Royal Botanical Gardens at Kew,* and subsequently I was invited to investigate the subject from the scientific point of view. Having during the last few months paid a number of visits to various points on the Hampshire coast and in the Isle of Wight to study the question in the field, I propose to give here a preliminary sketch of the history of the grass and the present extension of its area, adding at the same time a short technical paragraph for those who wish to make themselves familiar with the grass and the allied species which occur along with it.

The grass which Lord Montagu had in view is Spartina Townsendii, a member of

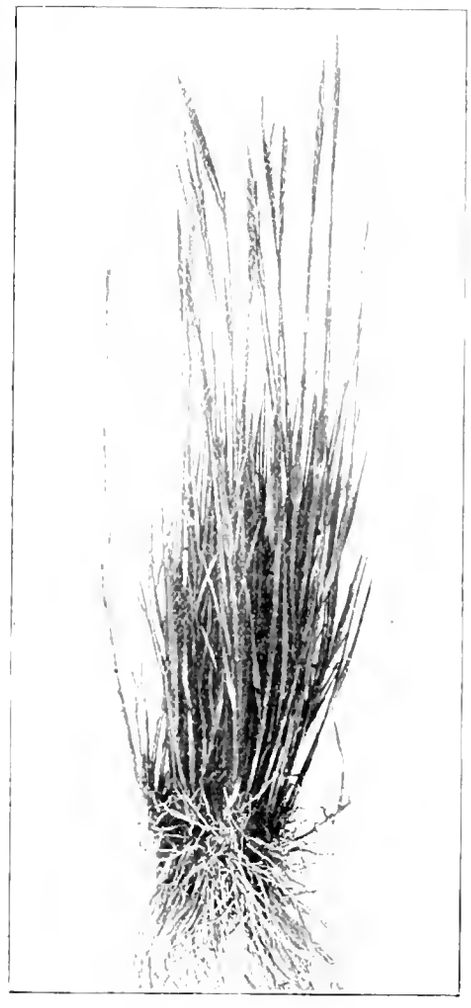

FIG. 17.—SPARTINA STRICTA
⅓ natural size.

a genus numbering about 18 species, mostly natives of America. With few exceptions, they inhabit sea marshes and muddy foreshores, under favourable conditions covering hundreds and even thousands of acres. Four species are known to occur in Europe (see map, fig. 20). Two, S. juncea and S. alterniflora, were introduced from the Atlantic coast of America, probably during the first half of the last century. S. juncea is confined to the western basin of the Mediterranean.

The other, S. alterniflora, was discovered by Loiseleur in the estuary of the River Adour near Bayonne in 1803, and then in 1829 by Borrer in the Itchen River near Southampton. A very complete account of it as it appeared there in 1830 was given by Brom. eld.† It has since then spread to some distance north of Northam Bridge in the Itchen River and to the Southampton Water as far as the Titchfield River on the eastern, and from Hythe to Redbridge on the western bank and from there to Millbrook. In France the grass has extended its area over a coast line of about 25 miles from Capbreton (Landes) to the estuary of the Bidassoa River.

Of the three remaining species, one, S. stricta (fig. 18) has been known for a long time (since 1629), and is beyond doubt truly indigenous in Europe. It is found in England along the east coast from southern Lincolnshire to the Thames and on the south coast from Chichester to the Solent. On the Continent it occurs along the Atlantic coast from the estuary of the Scheldt to near Gibraltar, and in a detached area at the head of the Adriatic. A continuation of the Atlantic area is found on the coast of Morocco from Tangier to Mogador. The other two species are S. Neyrautii and S. Townsendii. S. Neyrautii was discovered by Neyraut near Hendaye in the estuary of the Bidassoa River about 15 years ago, and was described by Foucaud (1894), who suggested that it was a hybrid between S. alterniflora and S. stricta, among which it is found growing.

S. Townsendii (fig. 18, see also map, fig. 19) was first recorded by the brothers H. and J. Groves in 1870 from Hythe in the Southampton Water; but we have evidence that it existed there as early as 1870. According to the brothers Groves, it was already in the 'seventies rather common on both sides of Hythe Pier. This for years remained the only station. In 1883 it

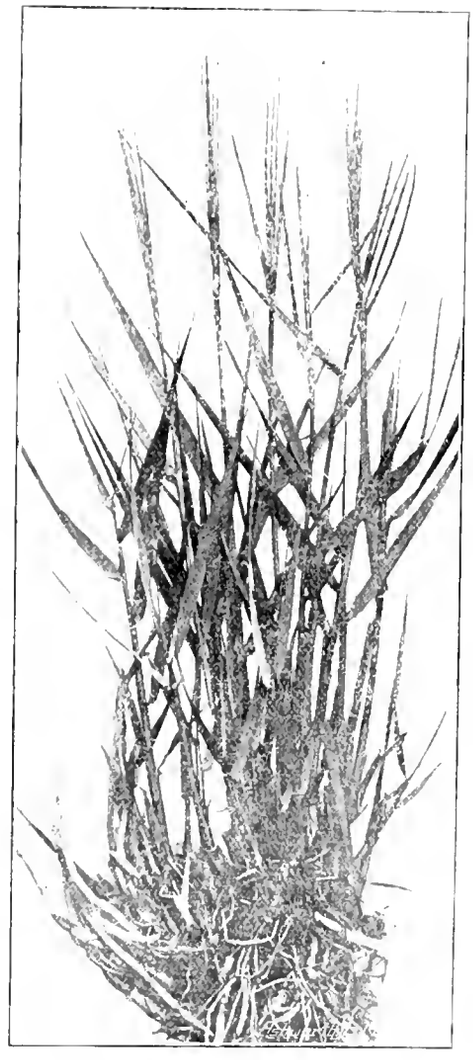

FIG. 18.—SPARTINA TOWNSENDII.
⅓ natural size.

had not yet travelled beyond Crockmore Head (two miles north of Hythe). In the Isle of Wight it was observed in 1893 (Yarmouth) and 1895 (Medina River); but nearly all

* See the article on "Mudbinding Grasses" in *Kew Bulletin*, 1907, No. 5, pp. 190-197.

† Bromfield in Hooker's *Companion to the Botanical Magazine*, Vol. 1, pp. 254-263, partly reprinted in *Kew Bulletin*, l.c.

other first records date from 1900 or after. To what extent it has spread during the last seven or eight years can be seen from the accompanying map. The area thus conquered by the aggressive newcomer extends at present over a coast line the extreme points of which are over 50 miles distant. It would be tedious to trace the advance in detail; a few instances may suffice. In 1893 Linton found "several strong patches" of it near Yarmouth on the road leading from that place to Freshwater. To-day it completely covers the mudbanks in the River Yar; it invades the adjoining marshland, and scattered marshes and mudflats between Hurst Castle, Milford, and Keyhaven; but in 1905 it was "plentiful and evidently rapidly increasing." On the roadstead of Poole Harbour a single small clump was discovered by Mansel-Pleydell in 1899. Six years later Riddlesdale found it "in some quantity" by the fever hospital at Poole, whereas Mr. W. J. Goddard describes it in a letter to Col. Prain, dated October 8 of last year, as occurring in hundreds of big clumps all around the harbour on nearly every mudflat.

To explain the sudden appearance of the grass three theories suggest themselves. It may, like *S. alterniflora*, have been introduced, as Lord Montagu thinks; but so far no Spartina corresponding to *S. Townsendii* has been found in America; or it may have originated by way of mutation. It could only have sprung from *S. stricta* which formerly occurred in Southampton Water; but *S. stricta* is little given to variation, and the differences are not of a character to support this theory. There is finally the hypothesis of the hybrid origin of *S. Townsendii*. This idea is not new; it was suggested by Foucaud in his note on *S. Neyrautii*. According to him, the latter was a hybrid of the formula *S. alterniflora* × *stricta*, whilst *S. Townsendii* was *S. stricta* × *alterniflora*. Two circumstances lend considerable strength to that view; first, the fact that *S. Neyrautii* as well as *S. Townsendii* actually combine not a few of the distinctive morphological and anatomical characters of the supposed parent species, and, secondly, their occurrence just in the two—and the only two—parts of the world where *S. alterniflora* and *S. stricta* have met, namely, at the head of the Bay of Biscay and in the Southampton Water. This coincidence is very remarkable and has almost the demonstrative force of an experiment, the more so as *S. Neyrautii* and *S. Townsendii* approach each other so closely that they could not stand as distinct species if one wished to leave the theory of their hybrid origin out of consideration.

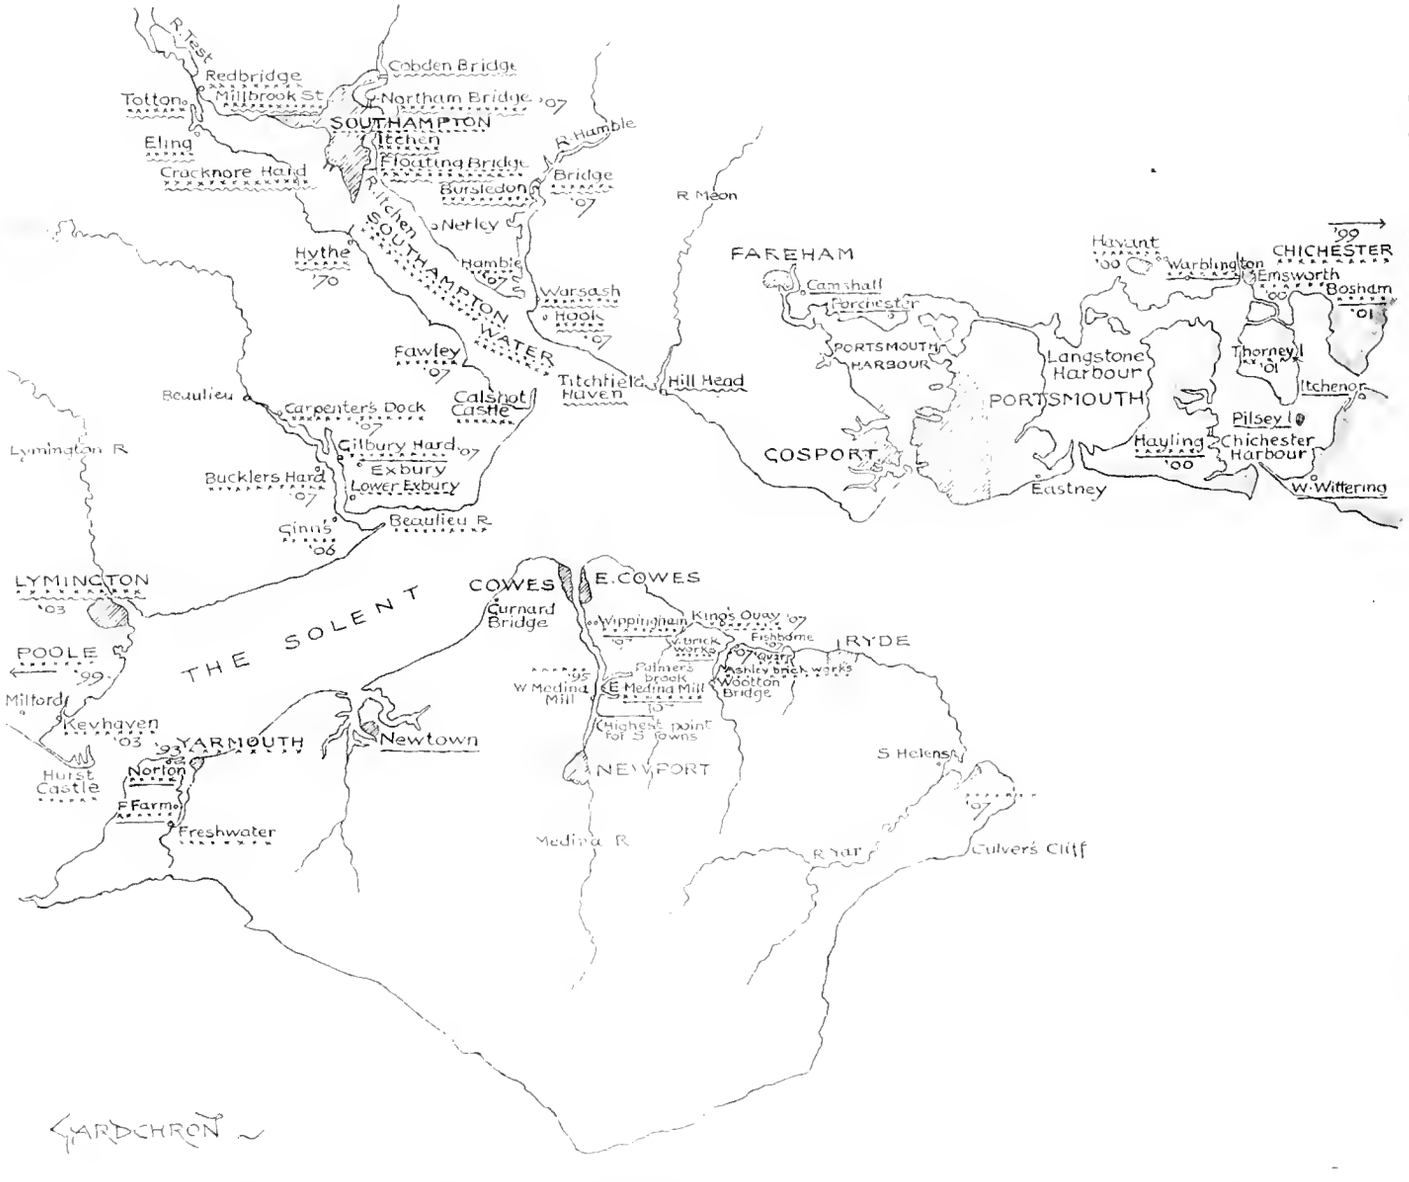

FIG. 19.—MAP SHOWING THE DISTRIBUTION OF SPARTINA. *S. STRICTA* (——— = STILL PRESENT, - - - - = NOW EXTINCT), *S. TOWNSENDII* (·····), *S. ALTERNIFLORA* (~~~~), ON THE COAST OF SUSSEX, HAMPSHIRE, AND THE ISLE OF WIGHT.

clumps may be seen as far up as Freshwater Church. A few years ago, Lord Montagu assures me, there was no trace of it in the Beaulieu River; now it predominates everywhere to beyond Buckler's Hard, to quote from a manuscript report by Mr. J. F. Rayner, of Southampton, "not only fringing the water, but running along every dyke, filling every pool and invading the broad borders of marshland," and its advanced posts stand within half a mile of Beaulieu village. In 1895 and 1896, so Cosmo Melvill tells us, there was none of the grass visible on the

But another question, perhaps of more practical interest, presents itself. What are the conditions that enable the grass to spread with such amazing rapidity and get so firm a hold? The dispersal is no doubt mainly by seed. The grains fall with the spikelets, which float and would be carried about by

the tides and currents until they are left on the beach or get caught somehow on the mudbanks. The grass does not seem to seed very freely, although it flowers profusely; but a few fertile clumps, as I have seen them, would after all give a good supply. When the seeds germinate, under natural conditions, we do not yet know. Possibly they behave like those of Zizania aquatica (a gregarious aquatic grass of North America), which lie in the water over the winter and germinate in the following spring. The seeds of these two grasses are remarkably similar, although the grasses are not allied at all. They have a highly-developed embryo, which, in S. Townsendii, is considerably larger than the endosperm and bright green throughout, including even the leaf-like scutellum, which suggests that the process of germination passes off very quickly and effectively. Once established, the seedlings would soon grow into tufts with plenty of stolons radiating in all directions and anchoring themselves in the mud by long, thread-like roots, which descend vertically. So firm is their grip on the soft substratum that even small tufts cannot easily be pulled up; and when I visited Quarr Abbey (Isle of Wight) after the heavy October gales of last year I could find no traces of uprooted Spartina on the beach, although there was an extensive bed of it on the foreshore. The grass is evidently wonderfully adapted to life on mudflats; to this must, however, be added as a factor favourable for its establishment the practical absence of all competition except where it meets with its congeners S. alterniflora and S. stricta. The former has so far made a good stand against the inroads of S. Townsendii, whilst S. stricta is evidently doomed to succumb.

The immediate effect of the appearance of this pushful grass on the mudflats of the south coast has been to relieve their barrenness and even to beautify them to some extent, and it has no doubt already affected animal life. Physical changes must follow, which, if the grass continues to flourish and spread, will react on the general conditions of the foreshore, resulting probably in the solidification and raising of the mudbanks; but this process will take time. It is at present barely beyond the first stage. Whether the result will in the end be beneficial or to the contrary will depend greatly on local conditions.

FIG. 20.—MAP SHOWING THE DISTRIBUTION OF SPARTINA STRICTA (——), S. TOWNSENDI AND S. NEYRAUTII (⊖), S. JUNCEA (✱), IN WESTERN EUROPE AND N. AFRICA.

In any case it will be a change worth watching and studying.

KEY TO THE BRITISH SPECIES OF SPARTINA.

1. S. stricta (fig. 17).—Forming small tufts ½ to 1½ feet high; rhizomes and stolons wiry; culms with a succession of up to 15 tight, firm, short sheaths, which, with the exception of the upper, soon throw off the blades; spikes usually 2, sub-contiguous, rigid, overtopping the leaves; spikelets 5½-7 lin. long, pubescent; second glume 3-nerved, lateral nerves delicate, tips hyaline.

2. S. Townsendii (fig. 18).—Forming large clumps or beds 2-4 feet high; rhizomes and stolons soft; culms with a succession of up to 10 or 12 somewhat soft sheaths, much increasing in length upwards, the lowest throwing off the blades; spikes usually 3-5, suberect, rigid, overtopping the leaves; spikelets about 8½ lin. long, delicately pubescent; second glume 3-6-nerved, with 1 or 2 stouter side nerves, keeled, keel ending abruptly below the short hyaline tip.

3. S. alterniflora.—Forming large clumps or beds 2-3 feet high; rhizomes and stolons soft; culms with a succession of up to 8 or 9 soft and very smooth sheaths, not throwing off the blades, which gradually decay; spikes usually 5-7, suberect, slender, and often slightly flexuous, overtopped by the long drawn-out blades; spikelets glabrous to the naked eye, 6-7½ lin. long; second glume delicately 5-6-nerved, keeled to the very tip. *Otto Stapf.*

FLORISTS' FLOWERS.

GROWING SWEET PEAS FOR EXHIBITION.

THE skill displayed in the cultivation of Sweet Peas may be said to increase year by year. This is not very reassuring to the man who may be thinking of trying his hand at exhibiting for the first time, but on the other side may be set the fact that many novices—that is, novices at exhibiting Sweet Peas—have scored signal successes at their first attempt. Another consoling fact, which has almost passed into a gardening truism, is that the soil which grows good culinary Peas will also grow good Sweet Peas, and the man who is a successful exhibit or of garden Peas is likely to succeed equally well with Sweet Peas.

The Sweet Pea resembles the edible Pea in liking a deep, well-tilled soil of a rich and holding nature, and plenty of moisture. It may be sown under glass in January or February, and planted out in April, or it may be sown outdoors in the place where it is to flower at any time from the beginning of March to the middle of May, and will give splendid results from either system of cultivation. In one important point it differs from the culinary Pea, and that is that in the ordinary course it does not form pods; once allow pods to form and ripen, and the flowering days of the plant are numbered.

The fact that it is not allowed to form pods has a decided bearing on the preparation of the soil, as most up-to-date growers who know the part that potash plays in the production of seeds will at once infer. As no seeds are produced, the liberal supplies of potash which are found of so much benefit to the garden Pea are not required, therefore there need be no special effort made to apply potassic manures to soils which are already in fairly good heart. What are wanted instead are phosphates, and those who is liberal in the use of these can scarcely fail to reap due reward, if only for the purpose he will presently have of feeling with nitrogenous manures in view of the reserved phosphates that he has stored in his soil.

But someone may say, Who could be foolish enough to waste nitrogen on Sweet Peas? Can they not get all they want from the atmosphere? In theory they can; in practice they cannot, and anyone who doubts this statement has only to grow two lots of plants side by side, one lot with nitrogen supplied and one lot without, to be convinced of its truth. Personally, I give my Sweet Peas nitrate of soda every week after they commence to flower, but they get a dose of superphosphate of lime as well. The latter is, I think, by far the best phosphatic artificial manure to use on the majority of soils. Even where bone flour gives equal results, I prefer the superphosphate, for bone flour is not at all nice stuff to handle out-of-doors, especially on a windy day. In soils that are already in a good state of cultivation, a dressing of 2 ozs. of superphosphate to the square yard will be found enough, either in preparing the ground or in feeding the plants after they are in flower. In very poor soils, a dressing of 4 ozs. to the square yard when preparing the ground will not be too much, followed by half the quantity when feeding subsequently. The superphosphate should be applied about a month before sowing the seed, or a week before putting out plants raised in pots.

While superphosphate of lime is the best artificial manure for general use, I would by no means recommend it in preference to farmyard manure, or even that from good stables, i.e., where plenty of corn is used. I always like to put plenty of animal manure in the bottom and about half-way up the trench in the autumn or early winter, and then give a dressing of superphosphate early in the spring, the date being determined by whether the seeds are sown outdoors or under glass. For this purpose the soil is moved to a depth of 3 feet, which allows ample room to get in two layers of dung without any coming into direct contact with the top 6 inches of soil. Had I to choose between superphosphate and animal manure, I should certainly select the latter.

The date upon which sowing is done must depend very largely on the date when blooms are wanted at their best. In previous years the National Sweet Pea Society has fixed the date of its London show early in July, and even southern growers have found it necessary to sow in January where the plants were raised in a cold frame. This year the show does not take place until July 24, and as the plants progress very rapidly after the commencement of July, sowing this year must be late if the grower would catch the plants, or rather the flowers, at their best. Just when to sow is a very nice problem, and one which has already greatly exercised the minds of many cultivators.

If one could correctly estimate the vagaries of the coming season, the task would be greatly simplified, for previous records would tell to a day when we might expect the finest flowers from a sowing on a given date; but this is beyond our powers, and past experience enables us to generalise but little. Thus, I have had flowers up to exhibition standard in the middle of July from a sowing made out-of-doors early in April, but I should not think of depending upon a similar sowing to give flowers for an important show this or any other year; one must have a little luck to it, and such a sowing would not give it. But I do not see why a sowing made at the beginning of March this year should not give flowers in profusion at the end of July, especially if made on pots in a cold frame. The seedlings would be up by the end of March or the beginning of April, and would be splendid little plants for potting out at the end of the latter month, an ideal time for planting out Sweet Peas for flowering profusely at the middle and end of July.

In light soils and warm situations, an outdoor sowing at the beginning of March would probably be in plenty of time. It is astonishing how quickly March-sown Peas come along compared with those sown earlier, and many a man has cut good exhibition flowers from such a sowing who had never thought to be in time. Outdoor sowing is, however, risky—so many accidents can happen to the seeds and young plants, and sowing in pots in a cold frame is always advisable. Novelties cost money, and are too valuable to waste on wireworms, slugs, birds, and other enemies. Raising in a greenhouse is even better than in a cold frame, providing that the pots are transferred to a cold structure immediately the young plants are above the soil. There is no fear of the seeds rotting in a warm greenhouse, and if any variety fails to appear in proper quantity, a second sowing can be made without much loss of time.

Five seeds round the side of a 5-inch pot has long been the favourite way of sowing Sweet Peas in pots, but exhibitors are now leaning towards the one-pot-one-Pea system. There is a good deal of labour involved in this practice, but it cannot be denied its advantages. Who has sown five seeds in a pot and has not had the annoyance of seeing, perhaps, two seedlings quickly appear, and then of having to wait a fortnight for the next? What this means, only the exhibitor who is pressed for time can really tell! With one seed per pot the case is totally different, as, should any of the seeds prove refractory, the pots containing them can be placed in gentle heat. Again, planting out is much more pleasantly and expeditiously done, and the plants experience no check.

It is very difficult to give a selection of the best varieties to grow, chiefly because so many of the novelties are sold out; indeed, many of the stocks were exhausted before November had run its course. Those who cannot get novelties must of necessity grow the older sorts, but they will be placed at a disadvantage in doing this where the competition is strong, for judges have to judge what is placed before them, and it is not likely that Mrs. Collier will score over Clara Curtis, or Dorothy Eckford over Etta Dyke, provided that both are in tip-top form.

Of varieties which should be readily obtainable I would select the following as the best twelve: George Herbert, Helen Lewis, Helen Pierce, Nora Unwin, James Grieve or Clara Curtis, Bobby K., Lord Nelson, Miss E. F. Drayson, Countess Spencer, Frank Dolby, King Edward VII., and Henry Eckford. For eighteen varieties I would add A. J. Cook, Etta Dyke, Mrs. Hardcastle Sykes, St. George, Dudley Lees, and Nell Gwinn. Twenty-four varieties should include: Queen Alexandra, Romolo Piazzani, Marjorie Willis, Dorothy Eckford, Sybil Eckford, and Mrs. Collier. In case of failure with Countess Spencer or George Herbert, Enchantress, Paradise, and John Ingman may be grown as reserves. *E.*

TREES AND SHRUBS.

CYTISUS NIGRICANS.

There is a wealth of splendid garden plants among the shrubby Leguminosæ that is wholly neglected in modern gardening, and particularly is this the case in the genus Cytisus and kindred plants. The power of individuals to thrive in the poorest soils, and to flower amazingly every season with no stint, together with the circumstance they are happiest with the wind blowing through them, should tempt many to give them a good trial. One pretty species of Cytisus named nigricans I have admired for many years as one adaptation to the worst possible conditions of a garden—a barren heap of stones, for instance. I have proved it many times, and I never neglect an opportunity of planting it where it can grow. In habit it is literally a dwarf twiggy specimen of the common Broom, and is generally less than 3 feet in height. The inflorescence differs greatly. In the case of C. nigricans position determines flower production. Where one can keep the plant literally struggling to live, there its flowers will prove a great delight. The long racemes that recall Laburnum, but are shorter and held suberect, are produced in late summer in quantity. Cytisus racemosus of the greenhouse is a good illustration of C. nigricans, but the floral yield in the latter species is much the greater. The plant is exceedingly hardy, and beyond an occasional trimming back, which all Brooms need, there is nothing to learn in its cultivation, except the following important detail, viz., plant young specimens only. Old and pot-bound plants never recover vigour, and youngsters outstrip these in the race. One of my pleasantest recollections of a northern rock garden is a grouping of C. nigricans in a rock wall. The rock face was literally draped with what I must describe as "nananised" Laburnums—a tumbled and elegant curtain of yellow.

SPIRÆA AITCHISONII.

New trees and shrubs of every description establish their position in gardens on a slow but sure principle, that of merit, and Spiræa Aitchisonii, withal a very beautiful plant that everyone admires, is no exception to this rule. It is the strongest and handsomest of all the shrubby Spiræas with which I happen to be acquainted, and those who would see it at its best must give it ample room for development and a soil moderately rich in plant food. In many respects it resembles the older S. Lindleyana, but is of taller habit and greatly excels in the richness of its leafage and its inflorescence. The stems exceed 10 feet in length, and are of a ruddy chestnut in colour all through the summer, whilst the foliage is the best example of elegant lobing I have seen in shrubby plants. Giant Spiræas such as this are ideal plants with which to form specimen clumps, either as units or as isolated groups; their bold, stately outline forbid a muddle at their bases, hence the poor display given by starvelings in a crowded shrubbery. A flowering specimen with 20 to 30 stems, most of which bear a spreading, flattened, plumy inflorescence almost white as Spiræas go, is surpassingly beautiful; the older stems dip to the ground in sheer luxuriance of growth, whilst the younger ones, upright as pollarded Ash, sway to and fro with every strong breeze. Two or three years are required for plants to develop into typical clumps, but the delay is well compensated by the annually increasing beauty of the specimens. This Spiræa is essentially a plant for the large garden, and it is one of the few "things" one can group effectively where garden and park meet. *G. B. Mallett.*

THE FERNERY.

ADIANTUM SCUTUM ROSEUM.

The cultivation of Adiantum cuneatum is in many nurseries giving place to A. scutum roseum. It is undeniable that in most establishments the former species, during the late autumn, winter, and early spring months, pass a miserable existence beneath the stages of the glasshouses, to be again brought out and afforded favourable positions when the sun mounts in the sky—therefore, at a season when A. cuneatum fronds have the least value. In glasshouses unprovided with overhead heating, which are not free from damp, or in which the necessary warmth cannot be maintained, the fronds suffer rapid decay. In the autumn, A. scutum comes in usefully, if the fronds have not been produced under too much shade, and so are not soft and liable to decay. The plants will then for a time, at any rate, take no harm if placed under the stages, and they will grow healthy and strong in a warmth of 60° to 65° Fahr. Plants will thus be provided for the Christmas season, such as no other Adiantum can equal. Another good quality of the plant is its rapid growth, which is unapproached by any other species. One-year-old plants, by good culture, may reach a height of 1¼ feet to 1½ feet, and in two years they may attain a diameter of 3 feet. A. scutum does not require so high a degree of warmth as A. cuneatum. *M.*

ORCHID NOTES AND GLEANINGS.

ORCHIDS AT WESTFIELD, WOKING.

THE compact and well-grown collection of Francis Wellesley, Esq. (gr. Mr. Hopkins), is famed for its rare Cypripediums, and for the excellent selection of white Cattleyas which it contains. The last white Cattleyas to flower were white forms of C. labiata. C. Mossiæ Rosalind, shown by Messrs. J. Veitch & Sons at the last Temple show, proves to be a very fine and free-flowering white form, with a slight bluish tint on the lip.

The Cypripedium houses have a very fine show of bloom, some of the finest of the C. Fairrieanum crosses which Mr. Wellesley has so carefully collected being still in bloom. The best of these is C. Thalia Mrs. Francis Wellesley (insigne Chantinii × Baron Schroder), a grand flower, which leaves nothing to be desired either in colour, size, or form. Many other hybrids of C. Fairrieanum are in bloom, including the distinct C. Primrose virginale, C. Niobe (Westfield variety), a very distinct and finely-coloured form; C. bella, C. Baron Schroder, the best and richest-coloured form raised by Messrs. J. Veitch & Sons; varieties of C. Norma and C. Arthurianum, the best of which is pulchellum (Westfield variety). A pretty new cross of this class is C. Mrs. Robert Lonsdale (Arthurianum × Lathamianum), which has a fine dorsal sepal closely spotted with dark purple. A number of varieties of C. insigne are in bloom, by far the finest being C. insigne Francis Wellesley, which may be said to be an improvement on C. i. Hatefield Hall, which is also in bloom. By comparison, the variety Francis Wellesley has a rounder and more flat dorsal sepal, which also bears a number of purple spots on the basal part of the pure white margin. C. insigne Aurora is a bright variety with a very polished surface to the flower; C. i. Wellesleyanum is very dark and with bright purple spots on the upper sepal; among other distinct forms is one which dates back to the collection of the late Mr. Day. A very fine set of Cypripedium Euryades are in bloom, varying much in colouring, but all pretty. An allied variety is C. Dicksonianum, which has a fine rose-purple dorsal sepal with a white margin. Cypripedium Ville de Paris is in flower in two varieties. Both are very remarkable and showy flowers. C. Mrs. Wm. Mostyn (Westfield variety) is also in bloom, its dark and richly-coloured flowers being conspicuous. C. Lucienianum superbum is a finely-coloured flower, and among the C. aureum section several good varieties are represented of allied crosses C. Tracyanum is a very attractive flower, with a fine white dorsal sepal, having an emerald green base and a broad olive-coloured band in the middle. C. Prospero Sedenii and C. Actæus Bruleyensis, two Veitchian hybrids, are very distinct, both having the greater part of the dorsal sepal pure white. The yellow forms of C. insigne are in flower. C. insigne Sanderæ is a favourite with all, but the darker yellow C. i. Sanderianum rivals it in beauty and is still not plentiful. C. King Edward (Rothschildianum × Lawrenceanum magnificum) is a stately flower and a robust grower. It is not yet generally known, being still rare. A good number of varieties of C. Leeanum were in bloom, also C. Minnie, a very neat and pretty flower; C. Actæus Sir Redvers Buller, a distinct form; C. Mandæ virginale, a large flower with fine white dorsal sepal, on which the emerald green lines are distinctly marked, and not shaded into each other, as in some forms, the petals also showing white ground colour; C. Pollettianum (Westfield variety), a very rich-coloured but bright-looking form; C. White Lady, something like C. Actæus Langleyense; several forms of C. Walhertæ; and many others.

In the Cattleya and Lælia house there are but few plants in bloom, but all are in fine condition.

WINTER FLOWERS AT ASCOTT.

IN the gardens of Leopold de Rothschild, Esq., Ascott, Leighton Buzzard, which have been in the care of Mr. John Jennings for more than 30 years past, the principal object has been to have flowers all the year round, and a specially good show in winter. That object has been successfully attained, and the declining days of the year 1907 witnessed a wonderful profusion of flowers, which continues at the present time.

Carnations are first favourites, and of these there are supplies every day in the year. At the present time a grand show exists in each of the several houses devoted to them, there being something like 10,000 specimens cultivated in pots. In the main span-roofed range the beautiful varieties in bloom include Britannia and Flamingo (scarlet), Perfection (white), Jessica (white flake), Mrs. Burnett (pink), Golden Eagle, Nelson Fisher (crimson scarlet), Pink Enchantress, Prosperity (white, tinged with rose), Lady Bountiful (white), Cardinal, Mrs. Lawson, America, and others. One division is nearly filled with Lady Bountiful, whose fine white, fringed, and fragrant blooms are pleasant to behold at this season; the pink Mrs. Burnett, the fine crimson Robert Craig, and the equally pretty Cherry Ripe.

The Carnations at Ascott are grown in 7-inch glazed pots, which Mr. Jennings is convinced have many advantages over the common flower-pot, the exterior glaze being more beneficial than otherwise. Some of the advantages are that glazed pots always keep clean and fresh in appearance and do not become green; it is not necessary to have the pots washed while the plants are in them, an operation which is sometimes attended with injury to the plants. The plants in glazed pots require less water, a matter which has to be borne very carefully in mind in winter, but is a distinct advantage in summer. It is not for Carnations alone that the glazed pots are used at Ascott, for they are in general use for all large batches of decorative plants.

Another method of growing Carnations adopted here with great success is to plant them in trays, or beds arranged on the ordinary staging on which a good layer of drainage material is placed and a bed of soil about 5 inches in depth to plant the Carnations in. Wires are run from front and back of the beds, so that the plants when tall enough may have their heads of bloom supported by cross ties of raffia or thread. The house so arranged presents a beautiful sight, with its profusion of evenly arranged flowers and buds; those at present in bloom being White Lawson, Enchantress, Robert Craig, and Fair Maid.

Cyclamen latifolium of a very fine strain fills one house with its fragrant blooms ranging from pure white to deep Carter crimson, some of the darkest having a very deep tint. In the next division the rose-pink Calanthe Veitchii is flowering, and a very fine lot of Cinerarias, outside being the Nerine pit, from which nearly a thousand heads of bloom were obtained last season.

A large temperate range has still a very fine show of Chrysanthemums, together with batches of scarlet Poinsettias, the feathery, white Moschosma riparium; Heliotropes, both dwarf and standard; variously-coloured Zonal Pelargoniums; and a great variety of other showy flowers. The warm ranges have several of the divisions filled with well-grown specimens of foliage plants, including Cordylines (Dracænas), Codiæums (Crotons), Acalyphas, Anthuriums, &c., and with these are arranged Lily of the Valley, Freesias, and other flowers, including a good show of Hippeastrums. The Hippeastrums are brought in from the cooler house at the rate of about two dozen a week and plunged in the slightly-heated bed in one of the warm houses, thus a succession of bloom is maintained, and the flowering season extended over a much longer period.

One division is filled with compact specimens of Coleus thyrsoides, all furnished with tall spikes of bright-blue flowers. These and similar soft-wooded plants for winter blooming are grown in glazed pots of comparatively small size. They are propagated by cuttings taken in June, and, by being brought on gradually, come into flower naturally in the middle of winter. Some plants of the orange-coloured Jacobinia chrysostephana are effectively arranged on the edges of the staging. One house in a span-roofed range is filled with Begonia Socotrana, its dense heads of bright pink flowers borne above the large and fleshly green leaves being very beautiful. This is an old species, not generally grown in gardens, and probably never seen in such beauty as it appears at Ascott. The pendant, moss-like edging in this house is of the Corsican Helxine Soleirolii. The next house contains the handsome Begonia Mrs. Leopold de Rothschild, fine bushy plants with larger rose-pink flowers than the original Gloire de Lorraine; and the white variety, called Turnford Hall. A larger warm-house has a fine batch of Begonia Gloire de Sceaux with a profusion of blush-pink flowers, borne well above the bronzy leaves. The roof is nearly covered with Ipomæa cærulea bearing hundreds of its charming blue flowers, to which nothing else in flower at this season can be compared.

A house of Zonal Pelargoniums, more Carnations, Lily of the Valley and Violets follow; and a glimpse through the end of one of the large houses reveals a fine show of large violet-purple blooms of Lasæandra macrantha and a batch of Cypripedium insigne in flower, the whole giving a fine example of what skill can do in producing flowers in the depth of winter.

The immense Rosary under glass in three broad, span-roofed houses, and filled with the choicest Tea, Climbing Tea, and Pillar Roses, has one section already started and beginning to produce blooms, and the other sections will keep up the supply until out-door Roses come into flower.

FORESTRY.

LARCH DISEASE AND LARCH APHIS.

I MUCH regret my inability to convince Mr. Forbes (see p. 38) that there is anything of value in the theory that Chermes insects are chiefly responsible for the spread and prevalence of larch canker, as the main object of my article in the *Gardeners' Chronicle* of November 23 last was to induce foresters to put the theory to the practical test. In Mr. Forbes' criticism, which appeared in this periodical on December 21 last, there are one or two points to which attention should be drawn.

1. The following sentence is not very clear, and may give rise to misconception: "The wool-secreting form of the aphis found on the stems of the larch is rarely seen in many districts in which the disease is rampant, and the most common form of the aphis is the naked mother which hibernates either in the axil of the buds or in the crowns of the dwarf shoots." The impression conveyed is that practically no wool-secreting forms of Chermes occur in those infected areas, but I would point out that the offspring of the naked mother found on the larch in summer are invariably covered with thick wool, so that if she is present, wool-secreting forms are bound to be present also. The sentence does not definitely state, but it certainly implies, that the naked mother is present in the canker districts referred to, and Mr. Forbes would certainly have stated her absence if it were a fact. We may take it, then, that wool-secreting forms are present in the canker districts, and that Mr. Forbes did not intend to convey the opposite impression. Probably these summer wool-secreting insects were not in his mind, because the majority of the insects are seated on the needles, and

possibly only exert a slight influence on the spread of the fungus living in the stem, but it must not be forgotten that a good many of these insects are also found on the young stems. I conclude, then, that Mr. Forbes is in reality referring to the hibernating generations only, in which case the meaning of the sentence is that Ch. viridis, the winter form of which has a covering of wool, is rarely found in the canker districts, and the most common form is the naked winter mother of Ch. strobilobius. It will be seen that this merely denies the presence in any quantity of one particular species, Ch. viridis, and as mentioned above implies the presence of Ch. strobilobius. In the article of November 23 it was part of my argument that the wool aids in catching the spores of the fungus, but the absence of wool in the winter Ch. strobilobius does not weaken it in any way. The deficiency is made up for by the amount of honeydew excreted, which is often so great that the insects' cast skins remain sticking to the end of the abdomen. These, with the empty egg cases, form a sticky little heap in which some of the countless spores floating in the air are bound to be caught.

2. Mr. Forbes goes on to admit that the sites usually selected by the hibernating Ch. strobilobius do frequently correspond with the sites on which blisters are ultimately found, but the only explanation offered for this coincidence is that the blisters occur on such sites "for the simple reason that they have to occur somewhere if they are to occur at all." Surely in face of the strong evidence pointing to the fungus being a wound parasite, a more probable explanation is that the blisters occur on these sites because they have to occur *at some place which has been previously wounded* if they are to occur at all.

3. The statement that no definite proportion exists between the distribution of Chermes and canker is one which must be received with caution. By the time that the blister shows itself, all evidence of any previous occupation of that particular site by a Chermes has vanished, and, unless the Chermes sites have been marked beforehand, it is impossible to speak with certainty about the proportionate distribution of the two diseases. No attempt to compile scientific records of the distribution of the two diseases has, so far as I am aware, ever been made, and the statement must be regarded as an opinion resulting from general observations and not as an established fact.

In conclusion, the only help Mr. Forbes can give is an opinion that certain causes unknown which favour the aphis attack may also favour the fungoid attack, even if aphides are absent, and a recommendation to let the aphis "take a back place." Against this the Chermes theory presents us with a definite problem for solution. I do not for a moment suppose that it will account for every attack of canker, since other agents besides Chermes wound the trees and so provide an entry for the spores. But there is no other agent which causes such countless wounds as Chermes, and the strong chain of evidence already forged by laboratory methods in support of the theory is surely sufficient warrant for foresters to put it to the practical test, especially when the matter concerns one of the most profitable timber trees in the country.

I am trying to arrange some further experiments on a larger scale which should settle the question beyond a doubt, and I shall be glad to hear from any owner or forester who is willing to assist me by placing at my disposal a small plot of ground in close proximity to a plantation where canker is already present, for the purpose of raising an experimental plantation of about 100 Larch. *E. R. Burdon, Ikeninlde, Royston, Herts.*

The Week's Work.

FRUITS UNDER GLASS.

By T. Coomber, Gardener to Lord Llangattock, The Hendre, Monmouthshire.

Queen Pine-apples.—Properly-prepared plants that have rested during the last two months are now in a fit state to be started into growth with a view to affording a supply of ripe fruit in summer. Provided the plants were carefully plunged in a suitable bed when placed in their fruiting pots, they should not be disturbed at the present time, as re-arrangement after the plants are fully developed cannot be done without causing them more or less injury. The atmospheric temperature of the house at night should be increased to 65° to 70°, and by day by artificial means to 5° higher, with a bottom heat of about 85°. Do not admit air to the structure until the atmospheric temperature reaches 80°, and then only sparingly, closing the ventilators early in the day, and at the same time syringe the spaces lightly between the plants. Promote humidity also on fine days by damping the floors in the morning and evening. By covering the roof of the house with mats on cold nights much less fire heat will be necessary to maintain the proper temperatures. The plants having been kept moderately dry at the roots during their season of rest should be moistened through with tepid water enriched slightly with Peruvian guano.

Figs.—To furnish a crop of fruit in succession to that expected from early forced trees in pots, a house of permanently-planted trees may now be closed. The old variety—Brown Turkey—has not yet been improved upon for the purpose of moderate forcing. If the trees, while making growth last season, had their shoots properly thinned, little, if any, pruning will be now required. Another point in successful Fig culture is that of confining the roots of the trees to fairly small firmly-made borders, provided necessary assistance in the way of nutritious top-dressings and applications of liquid manures are afforded during the growing and fruiting season. Good loam, with some crushed mortar rubble added, without strong manures, will satisfactorily answer for a compost. An old and good method of starting trees into growth is to make a hotbed of tree leaves and stable manure upon the floor of the house, accompanied with sufficient fire heat to slightly warm the pipes. This promotes a humid atmosphere, which, when assisted with daily sprayings of the trees, promotes growth and fruit development. Until growth has commenced, the borders should be only sparingly watered, but subsequently liberal supplies must be given.

Early vines.—At about this season many permanently-planted vines of such varieties as Black Hamburgh, Madresfield Court, and Foster's Seedling are started to supply ripe Grapes early in summer. We prefer to have the roots of these vines confined to inside borders, but in cases where outside borders are in use they should be covered with a firm bed of warm tree-leaves, and be protected from the elements by shutters or glass lights. An atmospheric temperature of 50° at night should be maintained until the buds burst, when a rise of 5°, with the usual increases by day, should be allowed. Disbud weak growths early, leaving the final selection of laterals until the fruit bunches can be discerned. Promote a moderate degree of atmospheric moisture, and keep the soil of indoor borders moist. Increase the supplies of water as the season of growth advances, and apply carefully diluted liquid manures, or top-dressings of artificial compounds.

PLANTS UNDER GLASS.

By Thomas Lunt, Gardener to A. Stirling, Esq., Keir, Perthshire, N.B.

Schizanthus hybrids.—No plants are more suitable for maintaining a fine display of bloom in the conservatory and greenhouse than a collection of the best Schizanthus. Plants that are intended for flowering early in spring should now be filling their pots well with roots, and may be given a little weak liquid manure twice each week at present, increasing the frequency of the application as time goes on. The plants flower very much better if potted firmly at the final shift, but the compost should be a freely porous one, to allow of it having to be made firm. A sprinkling of bone-meal should be included in the compost. At this time of the year and all through the growing stage, the plants must be kept in a position close to the glass and where they can be exposed fully to the sunshine, so as to keep the plants as dwarf and compact in growth as possible. If a cool plant-house is available for them, a suitable position may be found on a shelf near the roof glass in a cool vinery. They succeed very much better when treated almost as hardy plants. Schizanthus may be had in bloom from early in spring until the end of May, and even in June, but for this purpose successional sowings of seed should have been made from the middle of August last to the end of September. A strict watch must be kept for green fly, and on its first appearance the house should be fumigated.

Bulbs.—Such bulbs as are now being forced and have already filled their pots with roots require an abundance of tepid water at the roots. I have frequently found that hard-forced bulbs suffer for the want of moisture at the bottom of the pots, although at the surface the soil appears sufficiently damp.

PUBLIC PARKS AND GARDENS.

By James Whitton, Superintendent of the Parks and Open Spaces in the City of Glasgow.

Special studies.—Apart from the purely horticultural aspect of the question, there are other subjects which the young gardener, desirous of training himself for public service as a park superintendent, should set himself to study, the two which he will find most serviceable being land-surveying and plan-drawing. In all public schools drawing is one of the subjects upon which much stress is put by the authorities, but, unfortunately, unless in the secondary and technical schools, much of the drawing is aimless in character, and has no direct value in the future career of the scholar. Few young men, therefore, nowadays can say what those of past generations regretted, that they never had an opportunity of learning how to draw a map or simple plan. Having acquired some of the elementary principles of the art, the aspiring apprentice ought to improve himself by learning to draw plans properly to scale. This was the weak point displayed in the intricate designs of flower gardens with which many young men of our generation frequently beguiled themselves during the winter evenings. A few lessons from an efficient teacher, or the estate clerk of works, would materially assist the student, but, as frequently happens in country districts, these may not be obtainable, consequently the young gardener must fall back on his own resources and learn without the advantages a teacher would give him. It is not so difficult as learning botany alone. Let him begin by carefully measuring the garden in which he is employed, thereafter setting down his measurements on paper to a scale which should not be very small at the commencement. If he manages to do that correctly on his own initiative, he will, in time, succeed with others more intricate. The art of colouring his plans he can learn later, as the tinting is but a secondary matter to that of correct measurement and drawing.

Lessons in land surveying.—In regard to surveying, it is almost necessary, and certainly most advisable, that the student should obtain some practical lessons in the use of the "dumpy level" and the method of setting out the work. There being a good and a bad way of doing most things, the difference between a good and bad system of surveying only requires to be seen to be fully realised. Under a capable teacher the art can be readily acquired, and merely needs application and practice in order to attain efficiency in levelling and chain surveying. The plotting on paper of the ground to scale is likewise part of the art.

Value of knowledge.—In advising young gardeners to follow the course of study I have indicated, it must not be assumed that they, when parks superintendents, will always be called upon to practise either surveying or plan-drawing. Very probably they may never be required to do either work. But as no one knows what is before him, he who is best equipped has the best chance of succeeding, and, apart from the value of the general knowledge thus acquired, he is better able to scrutinise and read plans and maps which in the course of his business must come under his observation. Further, this training will enable the student to make out by measurement the various quantities on which he will base the estimate of costs of any proposed works. The question of costs is one of the most important points in every business, but too frequently one which private gardeners do not sufficiently study in detail. It is, however, essential in public service, therefore young gardeners should learn to note the cost of every class of work in which they take part, in order to fully qualify themselves in this respect for obtaining success in their future career.

THE ORCHID HOUSES.

By H. G. Alexander, Orchid Grower to Major G. L. Holford, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Zygopetalum Mackayi.—The great merit of this Orchid lies in the fact of its flowering in winter and lasting over so many weeks in full beauty. Its flowers are most fragrant in the daytime, with warmth and sunshine, but very much less perceptible on cooler or dull days. The cultivation of this species is not difficult, provided the plants are afforded a light position in an atmosphere of intermediate temperature and supplied with abundance of water at the roots when they are actively making growth. This is one of those Orchids which do not require much resting in the sense of keeping them at all dry at the roots. The bloom spikes appearing in the centre of the young growths point to the fact of careful attention being necessary to avoid any check to the latter at a season of the year not altogether the best for growth. They should, therefore, be encouraged to continue the growth as long as possible, for upon the perfect completion of this will, in a large measure, depend the production of flower spikes another season. The plants require a good compost to grow in, which should be made porous by including plenty of coarse sand, finely broken crocks, and charcoal. A mixture of two-fifths clean, fibrous loam, and one-fifth each of leaf-soil, turfy peat, and sphagnum-moss, is very suitable to the large fleshy roots. The plants dislike being disturbed at the roots. It is important that they should be kept in good health, for if once they get in bad condition it is not an easy matter to bring them back to a satisfactory state. The above remarks also apply to Z. crinitum.

Platyclinis.—This small genus of epiphytal Orchids is frequently known in gardens as Dendrochilum. The species P. glumacea is one of the most desirable kinds, and a great favourite with Orchid lovers. It is now in active growth, and should be given plenty of water, as it will produce its racemes during the spring months. P. Cobbiana will shortly commence to grow, while P. filiformis is still resting. These plants are grown here in the Cattleya house, and whilst making their growth they enjoy a liberal supply of water at the roots. During the resting season they are kept dry, only enough water being given them to keep the soil moist and prevent the pseudo-bulbs from shrivelling. The most suitable time to repot Platyclinis is shortly after the flowers are passed, and the compost used should consist of two-thirds good fibrous peat, or Osmunda fibre, and one-third clean sphagnum-moss, the pots being quite half-filled with good drainage.

Cœlogyne cristata.—If plants of this species, and its varieties, are allowed to become quite dry at the roots during the winter months, and the pseudo-bulbs allowed to shrivel, weak flower spikes are produced, and the blooms seldom open satisfactorily. It is necessary, therefore, to afford sufficient moisture to the roots as will preserve the pseudo-bulbs in a perfectly plump state from the time these are completed until the flowering stage is passed. These plants may be kept safely during winter in a minimum atmospheric temperature of 50°. Thus treated, a longer succession of bloom can be secured by bringing a few plants at intervals into extra warmth, as plants with plump pseudo-bulbs readily respond to extra heat and develop their flower spikes rapidly.

THE FLOWER GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Berkshire.

Border of herbaceous plants.—Some difficulty will frequently be experienced in the attempt to keep a good effect from early summer to late autumn in a border in which none but hardy species are cultivated. Some of the most popular of early-summer flowering plants are continually passing out of flower, thus causing blanks. From the point of view of effect the employment of two borders has much to recommend it. One would be the early-summer border and the other the late-summer and autumn, or, as I should prefer to call it, the "mixed" border. This latter would include hardy, half-hardy, and tender plants. The matter of arrangement must depend upon the selection of plants, the extent of the borders, and whether large or small groups or single specimens of particular species are to be cultivated. When large groups of one variety are preferred, this method can be the more readily carried out by the use of two borders, because of the increased number of plants from which selection can be made that flower at or about the same time. Prominent specimens or groups, say of three plants placed at irregular distances, and of varied shapes and heights, are attractive when the colours have been tastefully selected. The number of herbaceous plants that exhibit no marked dislike to varied soils is very great, but experience will best determine the most satisfactory species to grow to satisfy different requirements and tastes. The present is a very suitable time for preparing such borders. The aspect and extent should be made to correspond with the general surroundings, large, medium, or small. But a site should be chosen which is at least a reasonable distance from any high walls or large trees; the roots of the latter would soon overrun the border. The principal matter for consideration is that of the soil, for this should be deeply cultivated, and afforded manure, leaf-soil, peat, and the general accumulations of the rubbish-yard, according to its present condition whether poor or rich in plant-food and organic matter.

Shrubberies.—At this season time should be found to regulate the numerous occupants of the shrubberies, which, if neglected for any length of time, soon become a tangle. If flowering trees and shrubs are not examined annually, in order that the necessary pruning or thinning may be done, they usually become so intermixed that, after a time, a general overhauling is attempted, but such a severe operation is seldom satisfactory, and transplanting can then be scarcely attempted. If the knife and the spade are annually and skilfully used in thinning and regulating the plants in accordance with their habits of growth, the results are good. The thinning of most species of flowering shrubs can best be done after the flowering, but from pressure of work at that season the work is often overlooked; such as Lilacs, Laburnums, Thorns, Cherries, Pyrus, &c. Yet others such as Ceanothus azureus, C. "Gloire de Versailles," Buddleia Lindleyana, B. japonica, &c., Spiræas "Anthony Waterer," callosa, Douglasii, &c., Clematis Jackmanii, &c., flower better on the young wood, and may with advantage be cut back in early spring.

Frost.—We registered here on the 5th inst. 24° of frost; on the 8th inst 1.23in. of rain, and on the 11th and 12th inst. 20° of frost.

THE HARDY FRUIT GARDEN.

By F. Jordan, Gardener to The Dowager Lady Nunburnholme, Warter Priory, Yorkshire.

Root-pruning is indispensable in the case of fruit trees that have become too gross in growth through failure to produce crops owing to frosts, and also in the case of trees growing in soil that is too rich. The work should be commenced early in autumn, but if it is not already completed every effort should be made to carry it out. A little fresh loam, with plenty of lime rubble and charred refuse to induce the trees to make plenty of fibrous roots, should be in readiness before commencing the work. Small bush and pyramidal trees are best lifted; the strong roots can then be shortened, and the others spread out carefully nearer the surface, using a portion of the prepared soil for filling in. Large trees cannot be so conveniently lifted, therefore take out a trench 4 or 5 feet from the stems of the trees, according to size, tying up into bundles all the roots found during the process and working well under the ball of the tree, cutting away any strong, descending roots and pruning any strong roots that may be found. Lay in the others nearer to the surface, using a fair proportion of new compost. A good watering should be given to all wall trees after such an operation as root-pruning. If the trees are of very large size, one half only of the roots should be pruned in one season.

Pruning.—The season having been all against getting this work completed, the remainder of the pruning should now be hastened forward at every opportunity. Apples, Pears, and Plums in the open quarters should first receive attention. If the trees received the proper attention during last growing season, very little pruning will now remain to be done beyond shortening any leading shoots, according to the size of the tree and the amount of space available, and spurring in others that were overlooked to two or even four buds for the stronger growing varieties. In large trees that have filled their allotted space, very often the branches and spurs become crowded; in such cases some of the worst placed branches and spurs should be removed in order to let in more sunlight and air. After pruning give attention to any young trees and train the growths equally in any desired position by securing them with strong tar twine to stakes, so that plenty of sunlight and air may circulate amongst the branches, and these latter may become properly ripened.

Standard trees.—These are often more or less neglected, or are only examined at intervals of a few years, and then are generally thinned too severely at one time. They should be examined annually, and any unfruitful branches or useless spray removed so that light and air may have free access to the centre of the trees. Young standard trees should be carefully pruned for the first three or four years, leaving six or seven of the best placed branches to form the tree, shortening the leading shoots to about one-third their length. After the first three or four years very little pruning will be required, with the exception of the removal of any branches which cross each other.

THE KITCHEN GARDEN.

By E. Beckett, Gardener to the Hon. Vicary Gibbs, Aldenham House, Elstree, Hertfordshire.

Tomatos.—Plants which have been grown for fruiting in winter will have now passed through the most critical time, and much less difficulty will be experienced both in the setting and ripening of the fruit. Carefully prevent the atmosphere becoming stagnant; keep the roots in a moderately dry condition; maintain an even atmospheric temperature of from 55° to 60°, and apply liquid manure at every alternate watering to plants bearing fruits. Pollinate the flowers every morning as they open, and relieve the plants of any fruits as fast as these latter begin to assume colour, removing them to a slightly warmer atmosphere to complete the ripening. Two splendid varieties for fruiting in winter and early in spring are Sunrise and Winter Beauty; both are free-setting, and the fruits are of excellent quality. Repot successional plants raised from seeds sown last autumn into their fruiting pots, and cultivate them as sturdily as possible. Make another good sowing of reliable varieties. Fumigate houses containing Tomatos frequently to prevent attacks of the white "Snowy fly," to which the plants are so liable, and keep a sharp look-out for the "spot" or fungus disease that often causes much trouble and is spread the more easily by the presence of too much moisture.

Carrots.—Frequent sowings should be made during the next three months to ensure a regular supply of young tender roots, generally so much in request in all establishments. These may either be grown in portable frames on mild hotbeds or in heated pits. Use a finely sifted light compost, and make the soil moderately firm before sowing. Of varieties I may mention Inimitable Long Forcing, Favourite, and Early Nantes, all of these being suitable for this purpose.

Asparagus.—This vegetable, when lifted, forces with the greatest of ease when placed in a heated structure, but under no condition does it thrive better than when brought forward in frames on sweet, mild hotbeds, the quality of the Asparagus being far superior than when subjected to a greater degree of heat and grown in houses a long way from the glass. The same frame may be used for two or three batches, for as the season advances less heat will be required.

Potatos.—Continue to plant these in pits or frames at intervals according to the demand. Those which are in a forward condition will need careful attention both as regards earthing the pits and adding fresh soil for earthing purposes. The soil should be warmed to the same temperature as the atmosphere of the pit, and the warmest part of the day selected for carrying out the work. [illegible] the opposite direction [illegible] is blowing, especially so when the [illegible] the north or north-east.

S[illegible] of Early [illegible] Potatos, and box up Mint, [illegible] Onions thickly [illegible] "green Onions" in salads.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, JANUARY 18—
Soc. Franç. d'Hort. de Londres Annual Dinner. German Gardeners' Soc. meet.

TUESDAY, JANUARY 21—
Nat. Amateur Gard. Assoc. meet.

THURSDAY, JANUARY 23—
Gard. Roy. Benev. Inst. Ann. meet. and Elect. of Pensioners at Simpson's Restaurant, Strand, at 2.15 p.m.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—38·4

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, January* 15 (6 P.M.): Max. 48°, Min. 42°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, January* 16 (10 A.M.): Bar. 29·9, Temp. 33°, Weather—Cloudy.
PROVINCES.—*Wednesday, January* 15 (6 P.M.): Max. 47° Guildford; Min. 43°, Scotland N.E.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY
Sale of Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY AND FRIDAY—
Herbaceous Plants, Liliums, Bulbs, &c., at 12; Roses at 1.30; by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

WEDNESDAY—
Hardy Border Plants and Bulbs, Perennials, &c., at 12; Roses at 1.30; Palms and Plants at 5; 3,000 Lots Japanese Liliums at 1; by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

FRIDAY—
Odontoglossum crispum (imported), also established Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

"Herbaceous Perennials."

In different departments of work we often seem to pursue different methods, but in the last analysis these are always found to result in the endeavour to ascertain, and to state correctly, the relation of facts and things to one another. Since, however, the number of matters of which we have to take cognisance increases in proportion to the extent of our knowledge, we are driven in every branch of science, as in other lines of work, to classify them. As long as the things to be classified are under our own control the procedure is not difficult, so soon as we have agreed on a common basis. Thus the divisions of money are easy enough for most people to understand, though even here the particular £. s. d. basis on which we work in this country is not identical with that adopted elsewhere.

But no sooner do we endeavour to deal with matters that exist independently of ourselves, and so are not of our own devising, than difficulties of various sorts arise and confront us. For our classification can only be thorough, general, and logical, as long as it is dealing with things that are essentially different. Immediately we attempt to grapple with such complex matters as living beings we are speedily rendered aware that a really valid classification is hard to discover, if, indeed, it is not altogether unattainable. This partly results from the various cross relationships of different organisms to one another, and it is partly due to the different ways in which the same individual or structure may respond to altered environment.

A special application of the general position which we have just briefly underlined arises in determining what shall be the basis of our classification of plants for particular purposes. Thus, in connection with horticultural exhibitions and shows, it may be of importance to know whether a plant is to be regarded as a tree or a shrub, an annual or a perennial. The real difficulty of deciding lies in the fact that Nature does not work on the system of pigeon-holes. Everyone knows that numbers of annual plants are practically perennial, so long as they are not allowed to exhaust themselves by excessive fruiting, whilst a curtailment of normal longevity may frequently be brought about, as in the case of trees, by abundant bearing during early youth.

One of the questions connected with these matters, and one also that is continually cropping up, is concerned with the definition of the Herbaceous Perennial. It may as well be said at once that there is probably no single definition which will appeal to everybody as perfectly satisfactory. Certainly the one that is often given, viz., that it is a perennial the stems of which die down each year, cannot be regarded as such. As was pointed out last week by a correspondent, Pansies are among the plants that would be thereby excluded, not to mention many other examples that will occur to everyone.

Perhaps the best solution of the difficulty of arriving at a suitable definition would be to include in the first place all those perennial plants which possess "herbaceous," that is, soft and easily-crushed aerial stems, whether these have an annual or a longer duration, and, in the second, those perennials which lose their aerial stems every year. The latter feature serves as a fairly ready, though by no means universally valid, distinction between the shrubby and the so-called herbaceous perennials. Exceptions of course occur, and it may happen that a plant, the aerial parts of which are both shrubby and persistent in favourable localities, may be deciduous in others. The common Fuchsia forms a shrub or even a small tree in some districts, whilst in others it is annually killed back to the ground level.

A similar difficulty, though less apparent in practice, attaches to the question as to what distinguishes an Evergreen from a deciduous plant. Whilst no doubt exists in the great majority of cases, there are others—some Roses for example—in which the decision is not so obvious. The Rose may also be used to illustrate another point. Although many kinds must certainly be classified as shrubs, an exhibitor who made use of them in this sense at a particular show found himself in a difficult position, but at another show an exhibitor who also staged them as shrubs was upheld. Convention must, in the last resort, determine on which side of the line the "difficult cases" are to be ranged, for, to return to the question of herbaceous perennials, who is to draw the precise limit beyond which a soft stem is to be regarded as a woody one? Or, again, in the case of plants which are soft or woody according to circumstances, as Wallflowers, some Snap Dragons, &c. Which of the two forms is, for classifying purposes, to be regarded as the type?

There can be little doubt but that these matters might be made simpler for exhibitors if those responsible for compiling the Schedules would give greater consideration to the need for employing precise language, and for affording an indication by means of a foot-note, or in some other fashion, of any limitations exhibitors should respect in certain classes. For instance, a class for twelve herbaceous perennials stated as such, without qualification, would include most of the perennial bulbs, but in frequent instances in which Lilies have been included in such an exhibit, it has turned out afterwards that the Society's committee had intended to exclude bulbous plants; in some cases a special class was provided for such species. It cannot be too clearly pointed out that exhibitors have no other means of ascertaining the wishes of a committee in regard to a certain class than those afforded by the published directions.

Only those limitations and rulings which are definitely expressed can be binding upon exhibitors, and it is the duty of judges to interpret schedules according to the exact words, and not attempt to go beyond what is definitely expressed.

A correspondent in the present issue suggests that it might be found convenient to dispense with the use of the word "herbaceous" altogether. This would certainly prevent any trouble arising in regard to the alleged persistent or woody character of the stem, when it is required to be incapable of more than annual duration, or possess only soft, easily-crushed tissues. But its disuse would open up a field just as prolific in quicksands, for the flowers of shrubs, and even trees, might then be exhibited in a class where such species are undesirable.

In the same letter that we refer to, our correspondent, writing as a judge, states that in making an award he would consider a certain species a shrub or an herbaceous plant, according to his observations of the habit of the plants in the particular neighbourhood in which the exhibition was being held. But gardens vary much, even in the same locality, owing to differences of soil and subsoil, degree of altitude, and of shelter; therefore, such species as Phygelius capensis, Romneya Coulteri, certain Fuchsias and Pentstemons might have persistent aerial growths in the one garden, although in nine others they might be habitually killed to the ground each winter. In the concluding paragraph reference is made to exhibitors who frequently err by staging Sweet Peas and Canterbury Bells as herbaceous subjects. But surely the Canterbury Bell is to be regarded as an herbaceous subject? Such a plant would only be excluded, inasmuch as it is a biennial, by the use of the term herbaceous "perennial."

It seems to follow, therefore, that in compiling a class of the recognised type for herbaceous perennial plants, care should be taken in the first place to state whether or not bulbous plants may be exhibited, and, in the second place, to enumerate certain species the eligibility of which might otherwise give rise to misunderstanding.

The number of species concerning the status of which doubt can reasonably be entertained is not a very large one after all, and we believe that it would be worth while to arrive at some conventional understanding with respect to them. In this way it would be possible, both to remove existing sources of friction, and also to secure that uniformity of practice which, in the interests of fairness, is so much to be desired.

OUR SUPPLEMENTARY ILLUSTRATION.—The interesting species, Montanoa bipinnatifida, exhibited by Messrs. PAUL & SON, of Cheshunt, at the meeting of the Royal Horticultural Society on December 10, was illustrated in our issue for December 14, 1907, p. 419. The subject of our Supplementary Illustration to the present issue, M. mollissima, differs from M. bipinnatifida, chiefly in having smaller, entire leaves, a more branching yet stiffer habit, and the individual flowers are not quite so large, but more freely produced. Both species have white ray florets, and yellow disc florets. M. mollissima, Brongn, was first introduced into Europe by M. GHIESBREGHT, who forwarded seeds from Mexico to the Natural History Museum of Paris in 1843, where it flowered in the Botanic Garden the following year. Illustrations are given in the *Revue Horticole* for 1857, p. 543, and *Bot. Mag.*, tab. 8,143. The plant has been given several names. In the south of Europe, where both species thrive in the open air, it is more often named Montagnea grandiflora. The plant now illustrated flowered in the greenhouse at Kew in November. It grew to a height of 9 to 10 feet, and was growing in a 12-inch pot, being three years old from seed. M. bipinnatifida has also received several names. In the *Revue Horticole* for 1863, p. 370, the plant is figured as M. heracleifolia. This illustration, and also that of M. mollissima, from the same work, are reproduced in NICHOLSON'S *Dictionary of Gardening*. Polymnia grandis is another name for this plant. Judging by photographs of M. bipinnatifida received from India, it is a charming plant in that country, having been introduced from Mexico, where both species occur as natives. Montanoas are easy plants to grow, thriving in a loamy soil under the conditions of a cool greenhouse. During the summer the plants may be grown outside just like Chrysanthemums. Propagation is effected by seeds, cuttings, or suckers. Planted out in a large conservatory or greenhouse both species grow rapidly; the roots, however, seem to require confinement in order to induce the plants to flower freely. Neither species will make a good commercial plant, but those who have a large greenhouse to furnish in winter will find both of them of great service.

THE FLORAL COMMITTEE AMONG THE UNEMPLOYED.—At the meeting of the Royal Horticultural Society, on Tuesday last, the members of the Floral Committee, on meeting in their usual room on the first floor, were surprised to find that not a single entry had been made of plant or flower for the Society's First Class Certificate or Award of Merit. The surprise was natural enough, seeing that the chairman, Mr. WILLIAM MARSHALL, informed us afterwards that a similar circumstance had not occurred within his memory, and this extends over a period of 25 years!

FRUIT CONFECTION FROM UNRIPE GRAPES.—Experiments have been made at Thomery, in France, in converting unripe Grapes into a useful conserve. For example, the bunches of table Grapes are thinned in June and July of two thirds of their berries, and again at a later part of the season another third of the remainder is taken.

ADDITIONS FOR CALENDAR PUBLISHED LAST WEEK: THE WINDSOR, ETON AND DISTRICT ROSE AND HORTICULTURAL SOCIETY, at a committee meeting held on January 11, fixed the Annual Exhibition for Saturday, June 27. The report for the past year was considered satisfactory, the number of subscribers having increased whilst the exhibition entries were greatly in excess of all previous years. The hon. secretary announced that two additional Silver Cups would be offered in the coming schedule, one given by Mrs. FORTESCUE, Dropmore, the other to be known as the Islet Challenge Cup. At the general meeting it was decided to amend Rule 7 so that in future the local radius of the Society should be extended to include the whole of the county of Berkshire.—THE DEVON DAFFODIL AND SPRING FLOWER SHOW will be held at Plymouth Guildhall and Square on April 21 and 22. Captain PARLBY MANADON, Crown Hill, Plymouth, is secretary.—THE WEST OF ENGLAND CHRYSANTHEMUM SOCIETY'S SHOW will take place in the Plymouth Guildhall and Square on November 10 and 11. Mr. CHAS. WILSON is secretary.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION. The annual meeting and election of pensioners will take place at Simpson's, 101, Strand, on Thursday next, January 23, at 2.15 p.m. Afterwards at 6 p.m. the annual friendly supper will be held also at Simpson's, under the presidency of MARTIN H. DOCKER SUTTON, Esq., of Reading.

THE CROYDON & DISTRICT HORTICULTURAL MUTUAL IMPROVEMENT SOCIETY have arranged for the annual dinner to take place at the Greyhound Hotel, Croydon, on Wednesday evening, the 22nd inst., at 7.30 p.m.

APPOINTMENT TO CARDIFF CEMETERY. At a meeting of the Cardiff City Council, held on Monday, the 13th inst., Mr. C. WILLIS, superintendent of Cheltenham Cemetery, was appointed manager of the Cardiff City Cemetery. This appointment which was advertised in these columns a few weeks ago, is worth about £140 per annum, inclusive of house rent. There were originally over 170 applicants for the post, but the Parks Committee reduced these to a short list of five, who appeared before the Council on the date named. The successful candidate is 35 years of age, and has filled the position at Cheltenham for four years. Those selected to appear before the City Council were Mr. F. J. P. LOND, superintendent of Acton Cemetery; Mr. T. P. POWLEY, deputy-superintendent and manager of the General Cemetery, Wisbech; Mr. C. WILLIS, superintendent of Cheltenham Cemetery; Mr. HARRY ROUSE, foreman for the past 5½ years of the propagating department of the City Parks, Cardiff; and Mr. W. J. MELLINS, reservoir keeper, in the employ of the Cardiff Corporation.

IMPATIENS HOLSTII. Those cultivators who may have failed to grow and flower Impatiens Holstii to their satisfaction, whether in pots or the open ground, should not discard the plants but accord them another year a partially shady situation indoors or out of doors. In such the plants will surprise them by their wealth of bloom and good growth, the type form and its varieties being improved thereby to an equal degree.

"MY GARDEN DIARY FOR 1903."—This little work, published by Messrs. SUTTON & SONS, Reading, is a most useful as well as a dainty volume. Under each month are given, on the left-hand page, reminder notes as to the work that ought to be done, whilst on the right-hand page a blank space is left for notes and memoranda. It will prove a good shillingsworth to many a gardener, and especially to the amateur.

FATALITY TO A SCOTCH GARDENER IN AMERICA.—Early on the morning of December 27 last, it is reported in *Horticulture*, JOHN CLARK, aged 42 years, his wife and three children perished in a fire which destroyed their home at Watertown, Mass. JOHN CLARK was a salesman for the H. E. FISKE Seed Company, of Boston. His father, Mr. JOHN F. CLARK, is employed at the Botanic Garden in Washington, and it will be remembered by some of our readers that before leaving Britain for America he was gardener for many years at Wemyss Castle, Fifeshire. Deceased was a member of the Massachusetts Horticultural Society and the Gardeners' and Florists' Club.

THE AGRICULTURAL DEPARTMENT OF NEW ZEALAND. The annual report of the New Zealand Department of Agriculture forms a bulky volume of 450 pages, dealing, of course, with all kinds of matters agricultural. The planting of vineyards is extending, the last year having proved a very good one, both as to quality and quantity of crop. The growers are more and more discarding the European stocks in favour of the American ones that have proved to be more resistant to the attacks of Phylloxera. A warning is, however, given against the use of Isabella, Surprise, and Albany, since these, although of American origin, are only feebly resistant to the disease. Vine-growing ought to be a profitable undertaking, for it is stated that the yield of wine varies from 400 to 700 gallons per acre, and the price obtainable ranges from 6s. to 10s. per gallon. The department of pathology, which deals with the diseases of cultivated crops, is doing useful work, both of a preventive and remedial nature. As in all countries where fruit and other vegetable produce is grown in bulk, there is a tendency for pests of various kinds to multiply. This is merely a means of restoring the normal balance of nature which man is constantly disturbing, and it is only by unremitting attention, guided by an intelligent appreciation of the circumstances and causes of disease, that the cultivator can retain the upper hand.

TREE ROOTS AND GRASSES.—According to a writer in the *Journal of Botany*, the well-known difficulty of keeping up a good sward beneath trees has usually been ascribed to the shading of the grass, to the absorption of the moisture by the trees, and to the withdrawal of the plant-food by the tree-roots. Some experiments recently made seem to point to a more fundamental cause. In this competition of grass with trees, it is not always the grass that suffers. In several cases trees were found to be very materially affected by the grass growing beneath their branches. On the other hand, not all kinds of trees have a harmful effect upon other plants, though some certainly have such an effect. Potentilla fruticosa, a shrubby Cinquefoil, appears to be unable to live in the shade of the Butternut (Juglans cinerea), though it thrives in the same locality under other species of trees. In the case of the grasses, it was found that certain species of trees, notably the Tulip tree, Dogwood, Maple, Cherry, and Pine seriously checked the growth of grasses grown in their vicinity, and this injurious effect seems to be due to the excretion of substances by the trees that are harmful to the grasses. With regard to these statements by our American contemporary, we have remarked, both in this country and on the continent of Europe, not all of the so-called injurious species of trees act in the manner of those of America, for grasses of average strength grow under the Tulip tree, Maple, and Cherry when the shade is not dense. The dying out of the grasses is more often due to drip from the leaves, and this would be more frequently found in districts and countries having a heavy rainfall than in drier climates.

ECONOMIC BIOLOGY IN AMERICA. The *Proceedings* of the 19th annual meeting of the Association of Economic Entomologists contains, as usual, much interesting matter to all whose business lies with plants. Mr. F. M. WEBSTER contributes a suggestive article on the value of parasites in cereal and forage crop production. He shows how outbreaks of pestilent insects, such as the Hessian fly, were rendered harmless by the concomitant multiplication of other insects (Polygnotus) parasitic upon the eggs and larvae of the fly. Mr. WEBSTER rightly calls attention to the great ignorance which prevails on these parasitic relationships, which are, nevertheless, of the highest economic importance. Even in England, the value of the carnivorous lady-bird, and, still more, of its voracious larva, is often not appreciated. They are, unfortunately, not common enough; but we have known the larva to be destroyed under the impression that it was injurious to the plant!

FORESTRY IN SCOTLAND. The number of the *Transactions of the Royal Scottish Arboricultural Society* for January fully sustains the reputation of this important journal. Besides articles dealing with what might be called the high politics of forestry, it also contains many valuable papers devoted to the consideration of the cultivation and commercial exploitation of timbers of various sorts, e.g., the Douglas Fir, hardwoods, &c. Professor JAMES GEIKIE contributes an interesting article on "Soil: Its Origin and Nature," and a useful summary is given of the Afforestation Conference held in London in June last, at which the chair was taken by the President of the Board of Agriculture, supported by the President of the Local Government Board.

"'LIVE STOCK JOURNAL' ALMANAC, 1908."—This useful publication, issued by Messrs. VINTON & CO., London, gives an excellent summary of the events of the preceding year connected with matters associated with stock breeding. Many of the articles are of interest, and the whole forms a handy book of reference for those interested in the subject of live stock.

MESEMBRYANTHEMUM PYROPEUM.

AMONGST the annual species of Mesembryanthemum cultivated in this country, the one most commonly met with is the "Ice Plant" (M. crystallinum), with pretty white flowers and trailing habit. A species of much greater value for decorative purposes is the South African species illustrated at fig. 21. It is of easy culture and floriferous habit, succeeds in any light soil, and never fails to give a fine display of its lovely flowers throughout the whole of the summer months, or to ripen quantities of seeds. It is one of the prettiest annuals for a sunny position on the rockery or on a border at the base of a wall. The plant is of tufted habit, and forms a densely-flowered clump 6 to 8 inches across. The flowers are borne on peduncles 2 to 4 inches long, and are one inch and a half in diameter. They vary considerably in colour, most of them being light pink, with a dark red eye; others are self-coloured, varieties with white, pink, or red flowers being of frequent occurrence. The leaves are fleshy, linear, canaliculate, and about 3 inches long. The whole of the plant is covered with numerous small tubercular dots. The plant is catalogued by several nurserymen under the name of M. tricolor, under which name it is figured in the *Botanical Magazine*, t. 2141. In Nicholson's *Dictionary of Gardening*, fig. 565, it is illustrated under the name of M. tricolor, syn. M. *Pyropeum*, Haw. (*P. Karoo*).

FOREIGN CORRESPONDENCE.

CHRYSANTHEMUMS IN JAPAN.

THE Chrysanthemum on its native heath in the autumn is ubiquitous; every house has its cut flowers and potted plants; every garden is a mass of bloom; and even the meanest shop with its medley of saleable and unsaleable goods has a pot of the national flower growing in its fresh beauty amidst the general ugliness of its surroundings.

To see Chrysanthemums cultivated to the highest point of perfection it is necessary to visit the grounds of the Imperial Palace in Tokyo; there the cultivation of this plant has been carried on most carefully for many hundred years, and ... passing through these Chrysanthemum ... one has seen the most noteworthy specimens to be found in the Land of the Rising Sun. November is *par excellence* the month in which to make this visit, for then the flowers have attained their highest point of development.

At the present moment fashion ordains that the flowers should be small, so ordinarily one finds them smaller than at home; in fact, sometimes they are the size of a Michaelmas Daisy, and grow in almost equal profusion; these may be satisfactory from a fashion point of view, but they are decidedly disappointing so far as beauty is concerned.

The Japanese have always been experts in grafting several varieties on to one stock; this is still a leading feature in Chrysanthemum culture, and is very highly appreciated out here. Innumerable plants have from 10 to 20 varieties grafted on one stem, but the Palace grounds have plants on which 45 distinct varieties are shown on one healthy growing stock. The blooms of the smaller kinds reach their normal size under this treatment, but the larger kinds never attain their proper dimensions. The colouring being soft, with the exception of a bright canary yellow, these flowers tone together in a most wonderful way and the result is that the whole plant looks like a gigantic bouquet rather stiffly arranged.

FIG. 21.—MESEMBRYANTHEMUM PYROPEUM.

The plants, which are said to have no equal in the world, are trained upon Bamboo frames in the shape of a flat pyramid; some of the largest of these plants had a diameter varying from 9 to 11 feet, with a height of from 4 feet to 5 feet 6 inches. They presented a wonderful sight of blossom, for the heads of bloom varied from 400 to 700 on each plant. To see these plants, Japanese come from every corner of the country, and, indeed, they are well repaid for their trouble, the Chrysanthemum plants with their masses of bloom forming truly wonderful objects.

The Palace grounds are very extensive, and are of themselves well worth a visit, being

well stocked with Maple trees, the leaves of which in November are one blaze of every shade of pink, red, and brown colour; seen above the masses of Chrysanthemums, they form a scheme of colouring perhaps without a rival in any part of the world. *L. K., Yokohama.*

TO TEST FRUIT-TREE BORDERS.

In his weekly Calendars published in these pages during the past year Mr. Alexander Kirk recommended again and again that it is necessary for a gardener to thoroughly test the condition of the soil in a border before he can be in a position to decide whether or not a further supply of water is necessary for the roots. The surface soil, owing to the action of sunshine, or the drip from syringings, &c., may be drier or wetter than the bulk of soil below.

The implement illustrated at fig. 22 was devised by Mr. Kirk for the purpose of bringing to the surface a small quantity of the lowermost soil for careful examination. Mr. Kirk states that the implement "is made entirely of steel, weighs about 14 pounds, is 4 feet in length, and the condition of a vine or Peach border can at any time or place be ascertained by merely driving this instrument to the bottom of the border, and on its withdrawal the soil brought up can be examined, and it can be seen what the soil is composed of, and whether or not requiring water; this can be done without in the least disturbing the roots. When Carrots, Parsnips, or other root crops fail to succeed in old garden soil, this difficulty can be overcome by driving the instrument into the soil at every 6 or 8 inches, and after withdrawing it and filling the hole with a compost of sand, peat or wood ashes and a little artificial manure, firming the soil in each hole, placing a few seeds on the top and covering lightly. All practical gardeners know that one of the points in plant and Grape growing is to know when to give water and when to withhold it. As a rule, vine and Peach borders are too often dry at the bottom when least expected, thus causing Grape shanking and Peach dropping. The temperature of the border can be ascertained by placing a ground thermometer in the sheath of the instrument. This is specially important in early forcing. The soil tester is also an important implement to wood foresters, as by its use the soil and state of the ground can be discovered before planting."

KIRK'S SOIL TESTER FOR FRUIT - TREE BORDERS

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION. At no time does this Institution appeal with greater force to its friends and sympathisers than on the occasion of the annual election of pensioners, which will take place this year on the 23rd instant, when 18 or 20 only out of the 52 candidates accepted as eligible by the committee can be elected owing to the want of further funds. The candidates who may fail to secure election are equally as deserving as are those who will be successful; but, unfortunately for themselves, they have neglected to join the Society in their younger days, and, as a consequence, are now unable to secure the requisite number of votes. It may not be generally known that a change in the principle of election was forced by circumstances on the committee a few years ago. Under the old system, pensioners were placed on the fund by resolution of the committee. Now it is a question of votes only (excepting that the committee still has the power to add one or two non-elected candidates at their discretion), so that those candidates who can command the most votes are sure of election. In the light of this change, it is well worth while for all who are interested in this great charity for the aged and poor of our craft to peruse carefully the list of approved candidates issued with the present election voting papers. It reveals, to my mind, in a most forcible way the great advantage possessed by those who have for long subscribed to this institution, as against those who have subscribed for a short time only, or not at all, truly illustrating the old adage that "God helps those who help themselves." This comes very clearly out on reference to No. 10 on the list. It will be found that this gardener has been a subscriber for 28 years, and, as a consequence, he is entitled to 2,800 votes, making his election practically certain by his own providence and foresight. Another subscriber of 25 years is entitled to 2,500 votes, making his election also practically sure, and so on, every year's subscription adding so many votes to the subscriber's credit, and, as years go by, helping to make his chance of election more sure should he unfortunately require the help of the Institution. It takes about £4,000 a year to pay the pensions of upwards of 200 old gardeners, or the widows of such, and to meet this heavy disbursement the only income the committee have to depend on is £904 from investments, and £1,619 from annual subscriptions, leaving the balance for the committee to find the best way they can, and which is chiefly subscribed by a generous public, who have no interest in the Institution further than the love of gardening and of philanthropy. My object in writing this letter is to appeal to every gardener (and if the gardener is indifferent, to his wife, as the welfare of the charity concerns her as much as it does her husband) who may read these lines to join the committee in lending a helping hand to spread abroad the knowledge of this old and beneficent gardening charity, and to compel a more kindly and practical interest in its welfare, by inducing gardening friends not only to become subscribers themselves, but also to do their level best each to secure at least one more subscriber before another election comes round. The subscription of one guinea a year amounts only to a little more than 1d. a day. This small sum, besides affording an insurance against a rainy day in old age if needed, will afford the subscriber the happiness of knowing that he has done something to cheer and brighten the later days of some poor, deserving, old gardener or his widow. *Owen Thomas.*

A PROPOSED VEGETABLE EXHIBITION.—Few people, I think, beyond those especially interested in a business point of view will regret the disappearance of the National Potato Society. It is a fair question to ask of any of its late supporters, of what value was it in the furthering of Potato culture among the masses? It is all very well for seedsmen to offer 40 or 50 varieties, or more, of Potatos, with a special recommendation for each for some particular season, soil, or locality, but who, beyond the exhibitor, ever thinks of growing more than half-a-dozen for their value as a succession? Go into any market or greengrocer's shop in London or the provinces, and ask the purveyors how many sorts they handle or wish to handle. The answer in 99 cases out of every hundred will be, "Oh! as few as possible. Give me one sort in summer and another for winter; that suits my trade, whether they are 'Snowdrops,' 'Dates,' or 'Dunbars,' and you and your horticultural friends can take the rest." Those who have anything at all to do with vegetable shows, whether in summer or autumn, know what a position Up-to-Date takes with the exhibitor, whether it be as a round or a kidney variety. They know quite well the amount of confusion there is in sorts of Potatos, how easy it is to show one variety under half-a-dozen names. Such circumstances as these are sufficient to deter many persons from taking interest in a Potato society. I know many large gardens where the weekly demand of tubers is not less than ½ cwt. per day; yet, at the most, six sorts are grown. Why trouble to harbour more? *J. D.* (p. 13) brings forward suggestions for a vegetable society, but if such a society were started, like the Potato Society, it would have, I fear, a short existence. The main reason for this is the lack of outside support such a project would obtain. At almost every flower show vegetables are given a prominent place, and at such shows it is not difficult to discern how little is the real interest of visitors in that part of the display. The present fashion is not in favour of sightseeing in the case of such things as big Onions of one variety staged under several names, and which require the keenest expert to tell which is the correct type. The same remark is applicable to many other vegetables. Let us have a kind of vegetable about which there can be no quibbling in regard to names; the more often the names for one sort are multiplied the greater is the interest diminished. *Onlooker.*

NUMBER OF SPECIMENS IN EXHIBITS OF VEGETABLES.—Now that schedule-framing is in progress, attention might be called to the desirability of limiting the number of specimens shown in collections of vegetables. This is generally done, but at some small shows it is not the custom. At an exhibition in this locality last November, in one collection of six kinds there were 47 Tomatos, about 40 Potatos, and other kinds were in proportion. Another exhibitor staged 10 Cucumbers as one of his kinds in the same class. There is a danger of the smaller grower being beaten by another who stages a greater display. It is superiority of specimens that should be encouraged. *H. K., Faringdon.*

ECCREMOCARPUS SCABER.—Referring to the note by *F. M.* on the above plant, on p. 13, I may say there are three plants of E. scaber which have been established in this garden for several years. They are growing in loose calcareous soil, to which a quantity of leaf-soil was added at the time of planting. They are planted in an open position among a small collection of hardy Ferns, and allowed to ramble over some old tree stumps; thus the interesting and attractive blossoms are displayed to the best advantage, and are carried by the plants well into the autumn or early winter. The plants produce seed here very freely; each spring, seedlings appear in handfuls where the pods have fallen, and it is evident from the growth of those retained, that limitations of space alone prevent their naturalising themselves freely. *T. S., Walmsgate Gardens, Louth, Lincoln.*

SEEDSMEN'S SPECIAL PRIZES AND CORRUPTION. The thought that it is just possible special prizes offered by seedsmen at exhibitions of garden produce, when the conditions are that the seeds must be purchased from themselves, to enable gardeners to win prizes, constituted an infraction of the Prevention of Corruption Act of 1906, was in my mind, as in that of your correspondent "Clean Bill." It is evident that the provisions of the Act may be used even to this extent, as the special object of the prizes is to promote custom or trade. On the other hand, there is not a shadow of proof that this practice, so long in existence, injures the gardener's employer one atom. If seedsmen fear that their action in offering these prizes with the stipulation attached did contravene the Act, and they were to refrain from offering them, our exhibitions all over the kingdom would greatly suffer. Of course, if the objectionable stipulation was not added, the seedsman would have no interest whatever in offering the prizes. Still, even were the Act contravened by the stipulation, it is obvious it would not be so if show committees agree to accept these special prizes from seedsmen under the conditions "Open only to our customers," as then no specific act of corruption, or assisting corruption, could possibly be alleged. I do think, whilst the Act is a good one and is distinctly aimed to prevent trading corruption, it is being used somewhat unfairly so far as the gardener is concerned, in seeking to frighten him from accepting an absolutely innocent gift from any source, and, poor fellow, he is too often glad to get such gift, as his wages rarely reach that level his merits deserve, or such as would make him truly independent. Where an employer suspects his gardener of corruption ... the sooner they part the better for both ...

The Yellow Mirabelle Plum. Mr Ward says on p 28 that he only knows of one garden in which the Mirabelle Jaune Plum is grown. At Sawbridgeworth he can at any time see trees of this variety - bushes about 40 or more years old, 12 to 15 feet high and as much through the head Last year they bore very heavy crops, there seemed to be almost as many of the tiny crimson-spotted fruits as there were of the little dark-green leaves It is a miniature tree in all respects Sometimes these trees take a rest, but they generally yield a fair amount of fruit: the crop is, however, not by any means always preserved, since the rooks have a fancy for the little yellow fruits and are very early astir in the morning to get them As jam it is in every way worthy of the name "Mirabelle," firm and very rich Messrs. T Rivers & Son catalogue two varieties, the Mirabelle and the Early Mirabelle. The former, more properly known as the "Petite Mirabelle," has about a dozen synonyms, usually a good criterion of merit. The "Mirabelle Précoce" is, as its name indicates, an early variety Multiplication of synonyms ought not to occur nowadays, but some people go out of their way to make confusion It is always annoying to me to hear the Japanese Plums called Mirabelles, but why folk, who should know better, persist in calling the Cherry Plum Mirabelle, is beyond my comprehension One can understand Myrobalan being frequently mis-spelt - it is too bad that it should be mis-called as well. The origin of this Plum (Prunus cerasifera), like that of Jeames, is "wrapt in mystery." Loudon says "Europe, or according to some, North America" The county of Essex claims it almost as a child of its own, but it is probably a child by adoption only Who christened it I do not know, but it is evidently named after μυροβάλαν (myrobalanum), the fruit of a species of Palm (Terminalia Chebula), the behen nut, from which a balsam was made, now used in dyeing and tanning and also in medicine *H S R*

Libertia grandiflora. I was interested by the remarks and photograph of this plant published in the issue of *Gardeners' Chronicle* for January 4 There is here, in one of the herbaceous borders, a clump over 20 feet in circumference At various times many seedlings have arisen around it spontaneously. These, when transplanted in the spring, even when of considerable size, to other positions, have grown away quite freely Several of these have been transplanted in the ground, in some cases under the shade of coniferous trees, and they seem quite at home and flower well every summer Rabbits never molest them. *F. Street, The Gardens, Ardwell, Wigtownshire, N.B.*

Ononis arvensis (syn. spinosa). This charming little leguminous plant is one of the many British subjects which are so neglected by British gardeners The species flourishes wild in the open fields in the Midlands, and flowers practically all through the summer, its pretty little pea-shaped, rosy-pink blooms giving it a very pleasing appearance It is well worth a place in every garden, its procumbent growth and graceful rambling habit rendering it admirable for ornamental banks and rockeries It succeeds best in the full sun, in a well drained, turfy loam, and seldom thrives in over moist, low ground and damp, shady places *C H Middleton*

What is an Herbaceous Plant? On p. 438, Vol. xlii of the *Gardeners' Chronicle*, Mr Molyneux asks: "How would I treat Phygelius capensis and Pentstemon Newbury Gem if exhibited in a competitive group of herbaceous plants, and, curiously enough, the former species was in my mind when writing the note published on page 417 of the same volume The plant is obviously one that requires much discretion For example, in southern gardens, or others more or less favoured by situation, the Phygelius is distinctly of a "shrubby" character, and with that knowledge and the fact that naturally the plant is of a shrubby nature, I should in these circumstances so regard it But I could not adhere to that course were the plant exhibited in a locality where by the nature of the surroundings it is forced into being a strictly herbaceous subject, as is the case in most northern gardens. In these latter circumstances the plant is most usually cut to the ground each year by the severity of the weather, or at least so disfigured that the above-ground shoots are worthless. The plant is, of course, an exceptional one, and while fully retaining the "shrubby" character in some localities, does "annually produce flowering stems from the perennial root stock," and in this way, in part at least, brings itself within the required condition. By the same line of argument, however, the Romneya must be considered an "herbaceous" plant, and in this respect differs from that section of shrubby plants that produce the growth one year and flower from axillary "eyes" or buds a year later. Disqualification under such circumstances is perhaps not the best way out of the difficulty, as there is nothing to be gained by discouraging the exhibiting of two excellent subjects. I would rather suggest leaving out the word "herbaceous" from exhibition schedules, and substituting the words "hardy perennials" or "hardy border perennials" in its stead. Even these terms may require some explanatory footnote to avoid misunderstandings. Either of the above-named terms, while giving increased latitude to exhibitors, would still serve to keep in check those who constantly err by exhibiting "Sweet Peas," "Canterbury Bells," and other such species as "herbaceous" subjects. *E. H. Jenkins*

Prevention of Corruption Act, 1906.

I am gratefully indebted to your correspondents on the above subject, pages 28 and 29, *Gardeners' Chronicle*, January 11. I most heartily endorse their protest on behalf of gardeners who are alleged to be guilty of such dishonest practices as are suggested in Sir Edward Fry's letter. My experience of gardens and gardeners for upwards of 20 years past is that I can most emphatically deny such practices to exist amongst members of our profession collectively I admit there have been cases of individual gardeners who have proved themselves unworthy of their honourable calling Charity to our neighbours, sir, is due to all men, and I trust that our employers, and many there are who regularly read the *Gardeners' Chronicle*, will not be too prejudiced against their gardeners' honour. During the past ten years I have had the honour to be on intimate terms with some of the best gardeners of the north, and my firm opinion is that gardeners actually make sacrifices in order to serve their employers' interests. As for Sir Edward's opinions in reference to the seedsmen's bribe, that a gardener would pass over inferior seeds at the rate of 1s. in the £, and, in other cases, order more than was requisite, my experience, in the first instance, is such that I can faithfully defend the gardener's honour. In the second, if Sir Edward had a little practical experience he would think himself fortunate if he secured all things necessary for the upkeep of any garden he should happen to preside over In many establishments men are trusted with the keeping of all garden accounts What, indeed, would be the result if we were so dishonest to our employer as the letter in question appears to imply? In cases where employers are imposed upon, if we could trace the origin, it would be the master who is as much to blame as the man for offering such starvation wages. I have been interested in most of the correspondence on the above subject, and what impresses me most is the unlimited amount of legal advice we have been given gratis, or, at least for the modest sum of threepence Apologising for trespassing upon your valuable space *John Donoghue, Bandon Hill Gardens, Ireland.*

—— I am sorry to see that Sir Edward Fry's letter is not being taken up in the best spirit by some gardeners He was writing to a gardeners' paper, and he took up the points applicable to gardeners, not that he regarded them more than anyone else as rogues Had he been writing to an engineering paper he would have referred to undeclared commissions in the same manner he adopted about gardeners' discount. *H*

—— It is highly gratifying to me that, since this Act came into force, I have not been offered any present or discount in any shape or form from any nurseryman or seedsman It is a plain proof that nurserymen are honestly obeying the law, and I hope the mistrust and suspicion that is still in some minds may be quickly dispersed, and that a better feeling and understanding will prevail amongst employers and employed *H. Gardener*

SOCIETIES.

ROYAL HORTICULTURAL.

January 14 —The meeting of this society on Tuesday last was sparsely attended. Several exhibitors made a meritorious display of perpetual-flowering Carnations. There were very few Orchids. The best exhibit included a cork-made rock-garden, and this was shown by Messrs. W. Cutbush & Son. Messrs. Cannell & Sons showed Apples in excellent style and of good quality, all the produce being from orchard trees. Messrs. J. Veitch & Sons had a table of miscellaneous stove and greenhouse plants, forced plants of Rhododendron indicum constituting a bright feature.

Floral Committee.

Present: W. Marshall, Esq., and Messrs. H. B. May, Jno. Green, G. Reuthe, T. W. Turner, R. W. Wallace, Chas. T. Druery, Geo. Nicholson, Jno. Jennings, W. Howe, W. Cuthbertson, Arthur Turner, W. J. Grant, Herbert J. Cutbush, Chas. Blick, Geo. Paul, Chas. Dixon, J. F. McLeod, Jas. Douglas, Walter T. Ware, R. C. Reginald Nevill, and R. Hooper Pearson.

Half of the long table to the left of the entrance to the hall was occupied by exhibits from Messrs J. Veitch & Sons, Royal Exotic Nursery, Chelsea, which were mostly disposed in small groups of three or five plants—a better method than the heterogeneous mixture, the effectiveness of the plant when arranged as a group being easier to gauge and study. The useful winter-bloomer Leonotis Leonorus was repeated several times, as were Azalea indica in varieties, whilst Jacobinia coccinea and J. chrysostephana added to the brightness of the whole. Members of the Citrus family showed plenty of fruits on little bushes; and some had no fruits, but many blossoms, and probably the latter were the more admired. The orange, with variegated leaves and striped fruits, was nicely shown. Some capital Lily of the Valley, grown at Langley, and which had been retarded, and Moschosma riparium, a few Cyclamens, &c., were staged, together with small Ferns and Palms for contrast. (Silver-Gilt Banksian Medal.)

A group of hardy, variegated shrubs, Ivies, &c., was shown by Mr. L. R. Russell, of the Richmond Nurseries, Richmond, Surrey. The most conspicuous plants, however, were those of Buddleia asiatica in flower. Other plants consisted of Aucuba japonica vera, having dark-green leaves, and oval berries of rich scarlet colour; A. j. limbata, Eleagnus glabra marginata alba, E. Simonii, and E. macrophyllus, and Garrya elliptica, this latter species having numerous catkins on branches cut from out-of-door bushes. (Silver Banksian Medal.)

Perpetual flowering Carnations were shown in considerable numbers by Messrs. Hugh Low & Co., The Nurseries, Highgate Hill and Barnet. The flowers were shown as loose bouquets, in tall glasses The varieties included Rose Enchantress, Winsor, White Enchantress, Aristocrat, Helen Gould, and Mrs. Burnett. Some small plants of the same race were shown; among these were Cardinal, Red Enchantress, White Perfection, Oriflamme (a bright-coloured fancy), likewise cut blooms of R. Craig, Beacon, and others On the floor stood a half-circular group of Euonymus latifolius variegatus, with an edging of Aralia Sieboldii; and on the table a group of neat-looking, compactly-habited plants of their Salmon King Cyclamen, the flowers of which make a fine show by artificial light. (Silver-Gilt Flora Medal.)

Messrs W. Cutbush & Son, of The Nurseries, Highgate, London, N., and Barnet, Hertfordshire, showed cut flowers of various perpetual flowering Carnations, viz., Rose Dore (a fine flower showing great symmetry of form), Helen Goddard, Duchess of Portland (a flower of a light rose tint, occasionally flaked on some of the petals), and Nelson Fisher. Several groups of retarded Lilies were placed amongst the other exhibits with good effect, these being L. lancifolium, L. l. rubrum, L. auratum, L. longiflorum, &c., besides Spiræa japonica and Lily

of the Valley, also retarded plants. One part of the table was furnished with cork receptacles of rustic character planted with Alpines of species, small Conifers, Helleborus niger, Iris Histrio, I. Tauri, Meconopsis Wallichi, &c. There were also in bloom Daphne Mezereum alba, Hamamelis arborea, &c. (Silver-Gilt Flora Medal.)

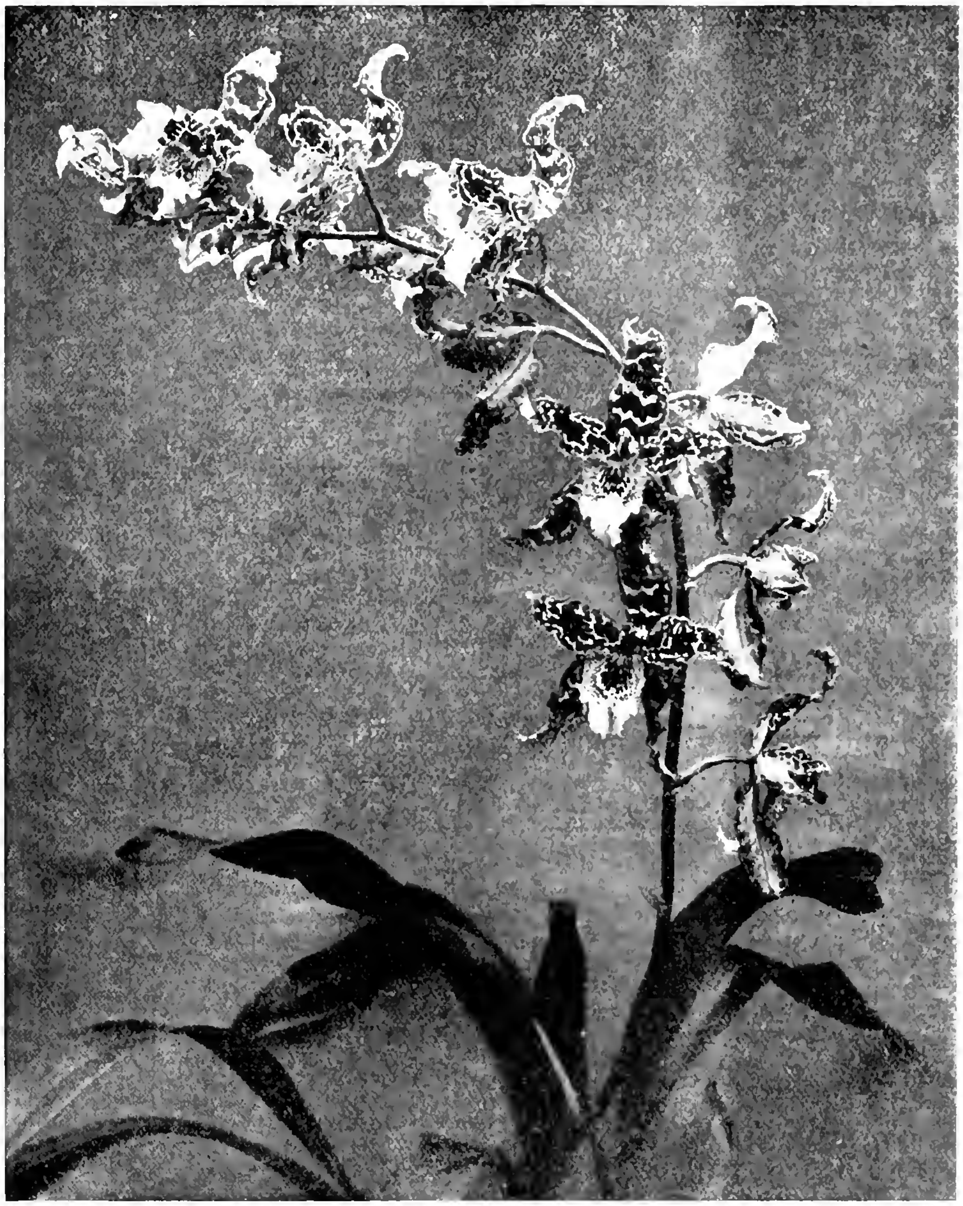
Alpine plants of many species were shown in pans and pots by Messrs. J. PEED & SON, Nurserymen, West Norwood, S.E. (Silver Banksian Medal.)

The Misses HOPKINS, Mere, Shepperton, exhibited a few hardy Primulas, Polyanthuses, Polygala Chamæbuxus, Lithospermum rosmarinifolium, &c.

Messrs. HUGH LOW & SONS, Enfield, staged a small, select group of Cypripediums, which included Thompsoni, Leeanum Clinkaberryanum, aureum virginale, aureum Hyeanum, Chrysotoxum, Mrs. Wm. Mostyn, Euryades, Maudiæ, several plants of the clear yellow C. insigne Luciane, a fine C. Chapmanii, &c., and for which a Silver Banksian Medal was awarded.

Messrs. HEATH & SONS, Cheltenham, also staged a group of Cypripediums, among which were C. Swinburnei magnificum, varieties of C. Euryades, C. insigne, and hybrids. (Silver Banksian Medal.)

Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. W. P. Bound), showed a fine specimen of Cypripedium G. F. Moore, Gatton



Photograph by J. Gregory.

FIG. 23.—ODONTOGLOSSUM × MACNABIANUM AS SHOWN BY MESSRS. SANDER AND SONS AT THE R.H.S. MEETING ON TUESDAY LAST. (AWARDED A FIRST-CLASS CERTIFICATE.)

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair); and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshay, W. Boxall, F. J. Hanbury, H. Little, Jeremiah Colman, F. Sander, A. A. McBean, F. M. Ogilvie, G. F. Moore, H. T. Pitt, Walter Cobb, J. Charlesworth, W. H. Young, H. G. Alexander, H. A. Tracy, H. Ballantine, J. Wilson Potter, R. Brooman-White, A. Dye, and C. J. Lucas.

The severe weather which preceded the date of the meeting, although a change had taken place during the night, was doubtless the cause of this being numerically one of the smallest shows of Orchids for some time past. The proportion of good new Orchids, however, was great.

Park variety Mrs. Wm. Mostyn, Chardwar variety × Sallieri aureum), a very strong-growing and handsome hybrid.

J. BRADSHAW, Esq., The Grange, Southgate (gr. Mr. G. G. Whitelegge), sent Odontoglossum venustulum "Apollo," which was given an Award of Merit, February 12, 1907. The fine white flowers had three parts of their surface covered with claret-red in irregular blotches; also the pale apricot-tinted Lycaste Skinneri armeniaca.

Mr. H. A. TRACY, Twickenham, showed Cypripedium insigne Berryanum.

HENRY LITTLE, Esq., Baronshalt, Twickenham (gr. Mr. Howard), sent a fine-flowered inflorescence of Lælio-Cattleya Callistoglossa ignescens.

Messrs. STANLEY & CO., Southgate, showed a white Cattleya Trianæ with a purple blotch on the lip.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, showed Cypripedium Helen II., a cream-coloured flower spotted and tinged with rose; also the new C. Helen II., variety Armstrongiæ (bellatulum album × insigne Sanderæ), a very handsome hybrid with wax-like white flowers, the petals spotted with purple, and the labellum tinged with yellow, &c.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr. Mr. Stables), showed the first flower of a very remarkable form of Odontoglossum Wiltonense, obtained by crossing O. Kegeljani and O. crispum Raymond Crawshay. The hybrid has a lemon-yellow ground colour, with large blotches of purple-brown; the very broad, [illegible]ate, white labellum having a large chestnut-brown blotch in front of the crest, and some smaller purple blotches at the sides.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), sent the pretty Cypripedium Mrs. Robert Lonsdale, and the fine C. Actæus Langleyense.

Messrs. CHARLESWORTH & CO., Heaton, Bradford, showed Odontoglossum crispum Lyoth, a very showy claret-purple blotched variety; a fine form of Cypripedium Fowlerianum; a distinct new variety of C. insigne with a very broad and distinctly-marked dorsal sepal; and a pretty hybrid of C. Sallieri.

AWARDS.

FIRST-CLASS CERTIFICATE.

Odontoglossum MacNabianum (Harryanum × Wilckeanum albens) from Messrs. SANDER & SONS, St. Albans. A magnificent hybrid (see fig. 23), in size, shape, and colour a distinct advance in its section. The large flowers, although plainly indicating O. Harryanum, were flatly displayed, the segments being undulate, and slightly recurved at the tips. The sepals were nearly covered with claret-red blotches, the cream-coloured ground only showing through in a few curved lines. The petals were equally heavily decorated with bright claret-coloured blotches, the tips and margin being also tinted with violet. Lip broad and flat, white in front and with a fine marking of rose colour around and in front of the crest. The remarkably fine colour of the flower is attributed to the good quality of the parents used, the O. Wilckeanum albens being the purple-spotted form once known in gardens as O. crispum leopardinum. The plant bore a fine spike of a dozen blooms.

Cypripedium Sultan (Mons. de Curte × Milo, Westonbirt variety) from Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Tetbury (gr. Mr. H. G. Alexander).—A noble flower, and one of the best which the famous collection at Westonbirt has produced. The large and finely-displayed dorsal sepal is yellowish emerald green, heavily blotched with dark purple, and having a pure white margin half an inch in width. The broad petals are tinged and veined with mahogany-red, the margins being yellow, and a few dark spots displayed on the base. Lip, mahogany-red, with a golden margin. Staminode, yellow; lower sepals large and divided, pale green veined with dark green and having a white margin. A very fine production.

Odontoglossum Rossianum (parentage unrecorded), from Baron Sir H. SCHRODER, The Dell, Egham (gr. Mr. H. Ballantine). This is the very handsome hybrid first shown in its undeveloped state by Baron SCHRODER in November, 1905. It has now attained fine proportions, and the plant shown had a very strong inflorescence. The flowers are large, very broad in all the parts; the ground colour light canary-yellow, the inner halves of the segments bearing broad transverse [illegible] and blotches of light [illegible] brown. Lip white, with a large brown blotch in front of the crest.

[illegible] Mrs. [illegible] Young [illegible] *Adhæsum* [illegible], from Messrs. [illegible] A. A. McBEAN, Cooksbridge. A [illegible] tardily [illegible] has been [illegible] Baron [illegible] a good many years ago by the [illegible] NATH YOUNG, who always thought [illegible] production, it failed to get [illegible] 1903, Mr BRIGGS-BURY [illegible] Award of Merit for it. The hybrid [illegible], however,

probably never been seen in so fine condition as those excellent cultivators, Messrs. McBEAN now presented it. The fine white upper sepal is tinted and veined with rose from a small green base. Petals and lip yellowish, tinged with red-brown. It is a characteristically fine flower of great beauty.

AWARD OF MERIT.

Laelio-Cattleya Ceruona, from Major G. L. HOLFORD, C.V.O., C.I.E. (gr. Mr. H. G. Alexander).—The parentage of this very brightly-coloured hybrid is not known, but it indicates L.-C. Ingramii on one side. The sepals and petals are bright magenta rose; the lip deep claret-crimson, with gold lines at the base.

Fruit and Vegetable Committee.

Present: A. H. Pearson, Esq. (in the chair), and Messrs. J. Cheal, W. Bates, A. Dean, G. Kelf, H. Parr, J. Davis, E. Beckett, G. Reynolds, C. Foster, J. Willard, O. Thomas, C. G. A. Nix, H. S. Rivers, P. D. Tuckett, and A. R. Allan.

A large exhibit of culinary and dessert Apples was made by Messrs. H. CANNELL & SONS, Eynsford and Swanley, a hundred varieties, distinct, being shown in conically-heaped baskets, all of them being orchard-grown and of marked good quality, the skins being free from blemishes and the fruits of large size. Of extra large size may be named the following varieties, viz., Charles Ross, Lord Derby, Mrs. Barron, Bismarck, Baumann's Red Reinette, Edward VII., Lady Henniker, Schoolmaster, and Lane's Prince Albert. (Silver-Gilt Knightian Medal.)

E. BIBBY, Esq., Hardwicke Grange, Shrewsbury, was awarded a Silver Banksian Medal for a collection of Pears, the fruits being in excellent condition; and a similar award was made to Miss C. E. MARTIN, of Willowbrook, Auburn, New York state, for fruits bottled in brandy and preserved in other ways, such as Peaches, Pears, Cherries, Melon and Mango, Strawberries, and fruits mixed with Okra, to be consumed as a sauce with meat. Probably Ochro, a Malvaceous plant growing in the West Indies and Central America, is meant, the seed covering of which is eaten.

LECTURE ON THE SOCIETY'S EXHIBITIONS.

MR. J. Gregory, the horticultural photographer, occupied the platform in the Lecture Hall in the afternoon. He said that he was not about to deliver a formal lecture, but to have a brief talk on exhibitions held by the society. At the old Drill Hall pictures could not well be taken, but in the present hall, because of the abundant light and space, it was possible, and he had 40 pictures to show his hearers, many of which had been taken in the hall. He wished to say that in securing such pictures he had always received from officials and visitors the greatest courtesy. The first pictures thrown on the screen, as illustrative exhibition groups, were from the "Temple" show held in 1907. These had to be taken very early in the morning. The charming rockery erected outside the tents by Messrs. CUTBUSH & SONS was the first picture, followed by the display of Cherries within the tents from Gunnersbury House. Then came a splendid group of Orchids staged by Messrs. SANDER & SONS, and next a portion of the same group enlarged. Afterwards came Major HOLFORD'S superb collection. The next pictures were from the Holland House show. Mr. AMOS PERRY'S beautiful water-garden and group came first, taken at 6 a.m. A fine group of annuals followed, then came Mr. MEASURES' collection of insectivorous plants, the individual specimens being none too clearly defined. The other group was the fine one of bulbous plants, shown by Messrs. WALLACE & SONS, of Colchester.

Then a move was figuratively made to the Vincent Square Hall, the first picture being one of Messrs. DOBBIE & Co.'s collection of Turnips. Next was that firm's very striking display of stabious flowers. Another of Mr. PERRY'S water-garden groups was shown, then came others representing Perennial Phloxes, a collection of Roses shown by Messrs. PRINCE & SONS, Oxford, a group of Cypripediums, Major HOLFORD'S grand group of Orchids, also as striking pictures two superb specimens of Cattleyas. There were two pictures of Mr. MOORE'S extensive collection of Cypripediums.

Turning to the fruit show, Messrs. BUNYARD & Co.'s fine collection of house-grown fruit and outdoor fruit made effective pictures. Some of the collections of hothouse fruits were shown, then came Messrs. VEITCH & SONS earlier exhibit of Gooseberries, and later their remarkable group of Japanese and Chinese vines. Mr. NORMAN DAVIS'S Gold Medal group of Chrysanthemums, Mr. PAGE'S beautiful collection of winter-blooming Carnations, collection of fruit from British Columbia and the West Indies, taken at the Colonial Exhibition, and several other pictures.

After the audience had left, a gentleman present threw on to the screen a few very beautiful coloured photographs, and we learn that at the next meeting he will present a number of coloured floral pictures of that description.

NATIONAL CHRYSANTHEMUM.

JANUARY 13.—On Monday evening last the Executive Committee of the above society held a meeting at Carr's Restaurant, Strand. Mr. Thomas Bevan presided. It was resolved that the late-flowering show be held as usual. It will take place at the Crystal Palace on December 2 and 3 next. A Floral Committee meeting will be held on the first day. A motion was made to alter the rules relating to judges. In future it is proposed they be honorary, but the proposition must receive the sanction of the general meeting. The draft annual report was submitted for approval, together with the accounts for the past year.

The Floral Committee dinner, to which any member of the Society is invited, will be held on January 27. The annual meeting of the Society will take place on February 3.

DEBATING SOCIETIES.

READING AND DISTRICT GARDENERS'. At a recent meeting of this association, held in the Abbey Hall, Mr. H. J. Jones, of the Kyecroft Nurseries, Lewisham, delivered a practical lecture on Chrysanthemums, explaining their culture from the cutting to the drawing-room and exhibition table. For ninety minutes the lecturer kept his audience fully interested as he treated minutely upon details of culture, &c., from the time the cuttings were taken to the show day when the flowers were staged for the judges' examination. He strongly impressed upon his listeners that attention to the smallest details very often decided whether the first or some other prize would be obtained. The first important point touched upon was naturally propagation, and under this heading advice was given as to the size of cuttings, nature of soil, the best method and time of striking, &c. Then followed directions as to the first shift, size of pots, subsequent shifts, constituents of a good soil, date and timing of buds, topping, housing, temperature, damping, ventilation, selecting and staging for show. There was very little time left for discussion, but much information was gained by the questions asked by Messrs. Hinton, Durward, Judd, Tyler, Wilson, and Goodyer. Mr. G. Hatch, of Cavenham Park Gardens, Mildenhall, Suffolk, sent 12 splendid bulbs of selected Ailsa Craig Onions which had recently been awarded 1st prize at the Bury St. Edmunds Show, and also 1st prize at the Norwich Chrysanthemum Show, and Mr. A. H. Bailey, of Leopold House Gardens, Reading, exhibited two seedling plants of Cryptomeria gracilis.

PANGBOURNE & DISTRICT GARDENERS'. The first meeting of the new session of this association was held on Wednesday, January 8, when a good number of members were present to hear Mr. A. G. Nichol, The Gardens, Strathfieldsaye, read a paper, entitled "A Chat on Vines and their Culture." Mr. Nichols described the proper method of making new Vine borders, also the operations of planting, pruning, training, thinning, &c. A good discussion followed, in which many of the members took part. *E. H. D.*

HORSHAM HORTICULTURAL MUTUAL IMPROVEMENT. The meeting held on January 2, under the auspices of the above society, was given over to a lecture, entitled "Canada of To-day," delivered by Mr. J. Cheal, of Crawley, illustrated by lantern slides. The lecturer gave an account of his recent visit to that Colony, and compared it with a previous one. Several interesting pictures of fruit plantations, Potato fields, spraying of trees, trial grounds, &c., were shown on the screen. *G.*

CARDIFF GARDENERS'.—The first meeting in the New Year of the Cardiff Gardeners' Association was held on the 7th inst., Mr. H. K. Farmer presiding. The lecturer for the evening was Mr. Harold Evans, "The Hardy Plant Nursery." Llanishen, who gave an interesting lecture on "The Water-Garden," which subject he divided into two parts—firstly, plants that live entirely in water; secondly, moisture-loving plants, trees, and shrubs that require to be cultivated adjacent to water. *K. J. B.*

Obituary.

J. R. PETCH.—The death of Mr. J. R. Petch, of Saffron Walden, occurred on Sunday night last in St. Peter's Hospital, Covent Garden, where he had undergone an operation. Mr. Petch, who was 71 years of age, was a well-known horticulturist. He was for some years head gardener to Mr. Samuel Mendel, a cotton merchant, of Manchester, and afterwards was traveller for Messrs. Richard Smith & Co., of Worcester. About 18 years ago he started in business as a seedsman and florist at Saffron Walden, and also travelled in the bulb and nursery trade. Subsequently he disposed of his business and became a traveller for Messrs. Russell & Co., of Richmond. He continued to live at Saffron Walden, and rendered useful service by acting as a judge at some of the flower shows in the district. Deceased leaves a widow and a large grown-up family.

MICHEL CROZY.—We regret to have to announce the death of M. Michel Crozy, at the early age of 38. M. Crozy had only recently succeeded his father, M. Pierre Crozy, the well-known Lyons nurseryman, who, some ten years ago, established a garden at Hyères (France), for the special cultivation of Cannas. Michel Crozy was held in affection and esteem by all who knew him. He leaves a widow and three little girls.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending January 11, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The *weather*.—On Monday, and until after the middle of the week, the weather was mostly dull, with occasional rain in all districts, heavy snow and sleet in the south-east of England on Tuesday night, and slight snow showers subsequently over various parts of the country. Towards the end of the week the sky became very clear over the whole Kingdom, but clouds soon reappeared in Ireland and Scotland.

The *temperature* was below the mean, except in Scotland N., the deficit ranging from rather more than 1° in Scotland E. to 5° in England S. At some extreme western stations the highest of the maxima were recorded on Sunday, but over the Kingdom generally they occurred on Monday, while in a few places they were registered a day later. In Ireland S. the thermometer rose to 56°, and in England N. to 55°, no district being without a reading as high as 51°. The maxima recorded on Sunday, and at the close of the week, were very low in various parts of England. The lowest of the minima were recorded on the 5th at the great majority of the stations, but on the 10th or 11th in some parts of England. They ranged from 10° in Scotland E. and the Midland Counties (at Balmoral and Raunds), and 12° in Ireland S. (at Birr Castle) to 17° in Ireland N., 23° in Scotland N., and 26° in the English Channel. The lowest grass minima reported were 1° at Balmoral, 4° at Llangammarch Wells, 5° at Birmingham, and between 10° and 15° at many other stations.

The *mean temperature of the sea*.—As a general rule the water was colder than during the preceding week on the east and south coasts, and warmer in the west and north-west, at Ballyglass the increase was as much as 3·9. The actual figures ranged from 45·6° at Plymouth to 37·8° at Ballantrae, and to 37·3° at Margate.

The *rainfall* exceeded the average in all districts except Ireland S. and the English Channel. Measurements of more than an inch were common in the north-east of Britain and in parts of southern and south-eastern England on Wednesday morning. At Heathfield (Sussex) the amount for the 24 hours ending 9 a.m. was 2·06 inches, and the depth of snow still lying was 8 inches.

The *bright sunshine* exceeded the average in England N., N.W., and S.W., and also in Ireland N., equalled it in the Midland Counties, England S. and Ireland S., and was deficient elsewhere. The percentage of the possible duration ranged from 30 in England S.W. to 20 or less in most of the other districts, and to 5 in Scotland N.

THE WEATHER IN WEST HERTS.

Week ending January 15.

Again several very low temperatures.—The first five days of the week were cold, but since then there has been a great rise in temperature. On the three coldest nights the exposed thermometer registered respectively 21°, 24°, and 21° of frost. On the coldest day the temperature in the thermometer screen never rose higher than 31°, whereas to-day the maximum reading has been 44°. Notwithstanding the thaw, the ground temperatures are still very low, the reading at 2 feet deep being 3°, and at 1 foot deep 4°, colder than is seasonable. Rain and snow fell on the first two days of the week, but since then the weather has been dry. During the frost there was no percolation through either of the soil gauges, but this morning there has been a little through both gauges. The sun shone on an average for 1 hour 2 minutes a day, or for half an hour a day short of a seasonable duration. On four days no sunshine at all was recorded. The first day of the week was rather windy, but since then calms and light airs have alone prevailed. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 3 per cent. *E. M., Berkhamsted, January 15, 1908.*

GARDENING APPOINTMENTS.

[*Correspondents are requested to* **write the names of persons and places as legibly as possible.** *No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting Box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.*]

Mr. F. DAVY, for the past 3½ years Orchid grower and plant foreman at Falkland Park Gardens, South Norwood Hill, S.E., as Gardener to M. JENKS, Esq., Hanover Lodge, Regent's Park, N.W.

Mr. FREDERICK C. LEGGE, for 8 years Gardener to Mrs. NICKALLS, at Patteson Court, Nutfield, Surrey, and 2 years at same address for Sir JEREMIAH COLMAN, Bart., as Gardener to J. F. CAMPBELL, Esq., Woodseat, Uttoxeter, Staffs.

Mr. W. PAYNE, for the past 18 years Gardener to the late C. D. ABEL, Esq., as Gardener to H. F. DONALDSON, Esq., Wood Lodge, Shooters Hill, Kent.

Mr. H. KILBORN, for 3 years Foreman at Adare Manor, Co. Limerick, as Gardener to G. R. DAVIES, Esq., Forest Hill, Hartford, Cheshire. (Thanks for contribution to R.G.O.F.)

Mr. THOMAS WATSON, for the last 4 years Gardener to JOHN BEST, Esq., Warriston House, Edinburgh, and formerly in the gardens of the Rt. Hon. Lord COLEBROOK, Abington, as Gardener to Col. KINNARD, Great Langley Manor, Guildford, Surrey.

Mr. S. J. MARTIN, Gardener to Mr. T. W. COWBURN, at Champneys Gardens, Tring, as Gardener to Surgeon-General Sir JOHN WOOLFRYS, at Woodbury House, Wells, Somerset.

Mr. J. EDGE, late of Millcourt, Alton, and formerly Gardener for some years to the late Lord HARLECH, Tetworth, Ascot, as Gardener to Sir JOHN H. JOHNSON, St. Osyth's Priory, Colchester.

Mr. C. DARLEY, previously Gardener at North Cray Place, Kent, as Gardener to C. C. LUPTON Esq., Ashfield, Old Malton, Yorkshire.

MARKETS.

COVENT GARDEN, January 15.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

REMARKS.—Apples from Nova Scotia and Canada are now selling more freely as the home grown produce is nearly exhausted, but a small quantity of the variety Wellington from Kent realise high prices. The sale for English black Grapes has considerably improved, but Muscat of Alexandria is scarce and the supply of "Canon Hall" is finished. There is a good demand for Pears, but the supplies are [illegible] small. Nectarines from the Cape [illegible] tenable. South African Strawberries [illegible] market, but the recent severe weather [illegible] deteriorated their condition. Beans [illegible] Guernsey are much dearer, and Cauliflowers [illegible] to sell well at advanced prices. *P. Z.* [illegible] *January 15, 1908.*

Potatos.

Kents: Up-to-Date, 100s. to 110s.; British Queen, 100s. to 110s.; Scottish Triumph, 100s. to 105s. per ton. **Lincolns:** Up-to-Date, 100s. to 120s.; Up-to-Date (Blackland), 95s.; British Queen, 100s. to 105s.; Sir Jno. Llewelyn, 95s. to 105s.; Maincrop, 105s. to 115s.; Royal Kidney, 90s. to 100s.; Evergood, 90s. to 95s. per ton. **Dunbar** (red soil): Maincrop, 130s.; Up-to-Date, 120s. to 130s. per ton. **Dutch:** Imperators 3s. 9d. to 4s. 3d.; Up-to-Date, 4s. to 4s. 6d.; Magnum Bonum, 4s. 3d. to 4s. 6d. per bag. **German:** Up-to-Date, 4s. 6d. to 4s. 9d.; Imperator, 3s. 9d. to 4s. 3d. per bag. The trade is fair, and arrivals heavier the last days, owing to the weather being milder. *F. J. Nicholson, Covent Garden and St. Pancras, January 16, 1908.*

COVENT GARDEN FLOWER MARKET.

The supplies of really good flowering plants are somewhat limited, and, though no very high prices are made, it is sometimes difficult to find just what is wanted. Ericas are plentiful and prices appear rather lower. On Tuesday fairly good plants were offered at 9s. per doz. Azalea indica in various colours sustain fairly good prices, but there are some which are not well flowered, which have to be cleared at a loss on the invoice prices they are imported at. The pink and red shades are more abundant. Spiræas from retarded clumps are good. Liliums are of doubtful quality just now; some good plants of L. Lancifolium rubrum were seen on Saturday, and a few fairly good plants of L. longiflorum, but the supplies are limited. The single Trumpet Daffodils, paper white Narcissus and Narcissus Tchamonios plenus are good. Hyacinths in pots are rather short in the stems. Good Cyclamen are not so plentiful. Marguerites are good, and now that Chrysanthemums are nearly over, better prices will be made for the Cyclamen. Solanums are still very plentiful, and most of those seen are well berried.

Foliage plants are well supplied. Most growers of Azaleas have now taken up the cultivation of A. Mosseri, yet I find some buyers will have the older plant, "Sieboldii." Cyperus Fixus has been good, and the price being low, it is used in the place of more expensive plants. Cyperus alternifolius is not quite so plentiful. Ferns in small pots are usually scarcer from now until the end of February. Small Palms are likely to make better prices.

CUT FLOWERS.

The trade has been very quiet. Carnation growers must feel disappointed with the returns, for prices are low, and it seems impossible to sell the flowers at any price. This morning at closing time there were heaps left on the market. Frances, as seen from some growers, is certainly a pleasing colour. Alpine Glow does not "take" well. Fair Maid is very good, and one salesman told me that he could do better with this than he could with Enchantress. Good scarlet Carnations seem to sell as well as those of any colour. Mrs. Burnett, which now comes from several sources, also sells well. Good white Carnations are in demand, but those of second quality do not sell readily. Of Chrysanthemums, Madame Charnat, from Mr. Henderson, is very good, and also a new white variety of similar form, whilst Lord Brooke still holds out. Yellow Princess Victoria is good. Mrs. J. Thompson and Niveum are the best white varieties. Winter Cheer and Framfield Pink are still seen, but will not last much longer. Jardin des Plants and Allman's Yellow are good for the smaller bunched blooms. W. Seward is a good dark variety. Good Roses are now scarce, and for best blooms of Bridesmaid 8s. and upwards per doz. is asked. Liberty is very bright, but rather small. The imported Roses arrive in good condition. Ulrich Brunner is very good, also Safrano and Madame Nabonnand. Yellow Trumpet Daffodils are of better substance now. Narcissus Soleil d'Or is arriving from Guernsey, also "Gloriosus" and The Pearl (or Scilly white). Tulips are abundant, and prices are considerably lower than they were the corresponding week last year, red varieties, which made from 12s. to 15s. per doz. bunches last year, now realise only from 7s. to 9s., and other colours are proportionately cheap. Best Parma Violets have advanced a little. Liliums vary but little. Many of the flowers of L. longiflorums seen are not of the best quality. L. auratum is rather small. Azaleas, Tuberoses, Camellias, &c., are fairly plentiful. Gardenia maintain their price. White Lilac is making advanced prices. *A. H., Covent Garden Market, January 15, 1908.*

ENQUIRY.

WANTED A NUT-MILL.—In the *Journal* of the R.H.S., Vol. xxxii., pp. 144-151, is an extremely interesting article, by Dr. Josiah Oldfield, on "The Value of Fruit as Food." On page 149, in meeting the objection that nuts are indigestible, he says: "An Orange's Nut mill will at once transform shelled Barcelonas or Walnuts, Brazils or Almonds, into a fluffy, snowy meal—dainty, digestible, full of nutrient fat." Could any reader tell me where such a mill can be got, and at what price? *A. C. Bartholomew.*

Answers to Correspondents.

CARBIDE OF CALCIUM: *E. Franklin.* This substance consists of compounds of carbon and lime; it is not of much value for plant growth and must always be used with a certain amount of caution. It can, however, be employed for the vegetable garden where the soil is already rich in organic matter (humus), with which it will combine and assist in the nitrification of the nitrogenous matter to form nitrate of lime. About 7 lbs. per pole of ground, equal to half a ton per acre, may be spread over the surface and dug in during the winter or early spring, so that it may become well incorporated with the soil before the time comes for seed-sowing.

CLUB-ROOT IN BROCCOLI, &c.: *L. I.* Only soils subject to the troublesome disease of Club-root, it is wise to withhold farmyard or stable manure altogether for a time, as this manure tends to develop the fungus. Soils infested with this disease should be dressed with an application of about one ton of gas-lime, applied in the winter and dug in. Ordinary quick lime can also be used with equal benefit. 10 to 15 cwt. per acre, equivalent to 7 lbs. or 10½ lbs. per pole or rod of ground. As the gas-lime contains certain properties which are poisonous to growing plants, it is best to dig this material into the soil when trenching; ordinary quick lime can be forked in nearer to the surface, but it should get well mixed in the soil before planting. The Club-root disease is very frequently carried by young plants from the seed-bed, therefore apply some lime to the patch of ground where you raise the plants. Be careful never to dig in diseased plants, nor throw them upon the manure heap or into a piggery, as the disease is not killed by passing through the stomach of an animal. Always destroy the affected plants by burning.

GARDENERS' TESTIMONIALS: *Head Gardener.* From your letter it would appear that you have received illiberal treatment at the hands of your late employer. If you think your case is sufficiently good, consult a solicitor.

HOPS REFUSE: *Taplow.* Spent Hops from a brewery can be used for the garden. They can be dug in as soon as received, when they will decompose in the soil and form humus matter and nitrogen. They are best suited for gross feeding plants, such as those of the Cabbage family. Half a ton to the acre or 7 lbs. per pole of ground would be a suitable application. A slight dressing of lime spread over the surface of the ground and dug in with the Hops will assist in their decomposition, and help to sweeten the soil.

HYACINTHS: *H. & S.* On dissecting the bulbs we were unable to discover any rudimentary inflorescences, a circumstance which would point to the probability that the bulbs were not in the best condition for forcing.

LIMESTONE AND CHALK: *G. F. S.* In nature lime generally occurs as chalk, which is a soft form of carbonate of lime; when pure it will contain about half its weight of lime. Limestone consists of lime combined with carbonic acid gas, and in some localities it is also combined with magnesia, when it is called magnesia limestone. For light, sandy soils quick lime made from chalk is to be preferred, while for the heavier and more clayey soils quick lime made from limestone is generally considered the best, because it is more caustic. If you can obtain, close at hand, lime made from chalk, by all means use it, as freight is a consideration when lime has to be carted from a distance. There are several wholesale firms scattered over the country who distribute lime made from limestone; it is ground finely, and delivered in sacks at about 25s. per ton. For pastures, chalk lime answers every purpose, and about 1 ton per acre should be applied once in five years. January or early in February is a good time to apply the lime.

LINNEAN SOCIETY: *R. D., Cape Town.* The entrance fee is six guineas, and the annual subscription three guineas. The address is Burlington House, Piccadilly, London, W.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

FRUITS: *G. McC.* Apple Queen Caroline.—*W. H. C.* The Apple is Pile's Russet. We cannot name the Pears from such small fruits.

PLANTS: *F. H.* We cannot undertake to name varieties of Chrysanthemums.—*J. S.* Catasetum tridentatum.

ROYAL HORTICULTURAL SOCIETY: *R. D., Cape Town.* Write to the secretary, at the address given in our last issue.

RULES FOR JUDGING: *C. L.* Copies of the Royal Horticultural Society's rules for judging may be obtained of our publishing department, price 1s. 7½d. each, post free.

STRAWBERRY MILDEW: *W.* The chemist is quite right, it is potassium sulphide that was recommended, not potassium sulphate.

SWEET PEAS FOR MARKET: *W. Nav.* There are a great many varieties seen in the market, and some of the newer ones may supersede those which have been most popular. At the present time, Miss Willmott is one of the most popular varieties of the rosy-salmon shade; other good varieties are Lady Grizel Hamilton, mauve or lavender; Dorothy Eckford, white; Salopian, red (but King Edward VII. and Queen Alexandra may supersede Salopian); Hon. Mrs. Kenyon, cream or primrose; Black Knight, Countess Spencer, and Gladys Unwin. Paradise is a favourite variety with florists. Navy Blue is the best of the blue shades, but there is not so much demand for Sweet Peas of this colour.

TO PRESERVE INFLORESCENCE OF SEAFORTHIA: *J. R. B.* The inflorescence of Seaforthia elegans is of considerable size, and its preservation in spirit would cost you much trouble and expense. Another method would be to place it in a vessel, afterwards gently filling up the vessel with fine, dry sand. By heating the sand to a temperature of 100° or 120° Fahr. the inflorescence would dry very quickly, and after removal from the vessel would be likely to keep intact. A simpler but less satisfactory method would be to suspend the specimen head downwards in a very dry atmosphere. In the drying process portions of the inflorescence would fall, but this perhaps would not destroy the value of the specimen for your purposes. Why not preserve a selected portion of the inflorescence rather than attempt to keep the whole specimen?

TULIP BULBS: *W. J. L.* We have dissected the bulbs, and are unable to find any signs of the formation of flower spikes. Probably they were too young, or they may have failed to perfectly mature last season, in which case they would be unsuitable for forcing.

VINE CULTURE IN NEW ZEALAND.

(See Supplementary Illustration

THE British gardener has just cause to be proud of the magnificent bunches of Grapes that are to be seen at our Fruit Exhibitions. Beyond all question they bear favourable comparison with the best that are grown in any other part of the world. There is no branch of exotic fruit-culture in which we excel so much as that of producing Grapes in their highest state of perfection.

But if the Colonist on the far-distant shores of New Zealand enjoyed equal facilities for producing Grapes similar to those we admire so much, I am convinced that he would run his brother at home a hard race for supremacy. When travelling in the Antipodes a few years ago it was my good fortune to visit many fruit-growing establishments and note their contents. In the course of my tour I had the great pleasure of meeting several gardeners that I knew before they ventured out to pitch their tent on the land of the New Dominion. In no case did anyone say he regretted the step he had taken; all admitted the hardships and uphill battle of the first few years, but their proud boast is, "We are now our own masters." There is no grand nobility in the Colonies with stately homes and magnificent gardens. All here is industry, each striving in his own way to make an independent, comfortable, and happy home for himself and his family.

The vegetation of New Zealand is truly wonderful, especially in the North Island, where, during my visit in December and January, Sweet Peas from 6 feet to 7 feet high might be seen in almost every garden, and, to all appearances, they would grow 2 or 3 feet higher before the autumn set in. Roses grow and flower splendidly. For instance, it is not uncommon to see the well-known variety Frau Karl Druschki with blooms as large as a well-grown incurved Chrysanthemum. I was informed that no stimulants are used in producing these splendid flowers. During the mild winters, horses and cattle graze on pastures all the year round, and in consequence little or no farmyard manure can be obtained. I mention these matters to show what can be done in a country where Nature has been so generous in providing a rich soil, with a genial climate suitable for the production of food for both man and beast.

On the slopes of Henderson Hills, 10 miles north of Auckland, there may be seen several newly-planted vineyards, but as the vines have not yet reached a bearing condition I can only say they looked promising. The favourite variety seems to be Black Hamburgh.

The method adopted in growing them is to plant the vines in rows 4 feet to 5 feet apart, and about 4 feet from plant to plant. A strong stake is driven in the ground to each vine; these stand about 4 feet high, and at about 18 inches from the ground a wire is stretched from end to end of the rows.

The young shoot is tied to the stake, and is stopped when it reaches the top. Next year this shoot is tied to the wire and produces fruit, another young shoot taking its place as leader. When the fruiting rods have yielded their crop they are cut out and their successors take their places on the wire. At present these vineyards are but in their infancy. As the bush gets cleared they may extend into hundreds of acres in this favoured district. The vineries of Mr. Mason, who left England nearly half a century ago, are situated near Auckland. They are span-roofed, of various sizes, all erected in very primitive fashion. Notwithstanding this drawback, the vines yield enormous crops of Black Hamburgh in what may be described as useful-sized bunches, well finished, and as black as Sloes.

My next visit was to the fruit gardens of my nephew and namesake at Otahuhu. Here everything is modern and up-to-date. He has three span-roofed vineries, each 100 feet long and 20 feet wide. In two of these the vines have been planted four or five years. The only preparation the borders get is a thorough forking over, a dressing of bone-dust, and, after planting the vines, a covering of litter is provided.

At the time of my visit the Grapes were well advanced in colouring, showing splendid bunches and berries hanging all over the roof from top to bottom, many bunches weighing from 3 to 4 lbs. each. The varieties Mr. McIndoe grows are Black Hamburgh and Barbarossa, Pearson's Golden Queen, Gros Maroc, Gros Colmar, and Mrs. Pearson. The black varieties are black as black can be, but what appeared most remarkable was the clear, bright golden-yellow colour of Golden Queen, with such a "finish" as I have never seen it develop in Britain. In New Zealand it bears abundantly and is the most popular yellow Grape grown. The third vinery was erected last year, and is planted entirely with Gros Colmar, the vines being planted outside, and for the first year are trained up on the roof, while the inside of the vinery is entirely filled with Tomatos. They had reached their allotted space in as fine rods as anyone could desire. I was told that at pruning time they would be shortened back to 6 feet, then taken through holes in the sides of the house.

MR. KNIGHTS' VINERIES.

My next place to visit was Mr. Knights' fruit gardens at Mangere, near Ellerslie. Here I found several vineries, all span-roofed of various lengths and widths, apparently home-made structures. The varieties grown there are principally Black Hamburgh and Golden Queen, with a few rods of the same varieties I saw at Otahuhu. The crops are marvellous, certainly the most wonderful I have ever beheld in any part of the world, the bunches appearing as if hanging just clear of each other all over the roof. Notwithstanding the great crop, bunches and berries are a good size; both black and yellow varieties were splendidly coloured. Mr. Knights informed me that, beyond forking over the soil and giving a good dressing of bone manure, the borders had not received any preparation whatever. I noticed the roots had an almost unlimited run in what appeared to be deep, warm soil that may have at some time been the lava thrown up from a neighbouring volcano now defunct. Many of these are to be seen in this district. I may add Mr. Knights and his wife hail from Jersey, and he has brought his Grape-growing knowledge to some purpose to New Zealand.

The accompanying photograph (see Supplementary illustration) was taken a few days after my visit to Mangere, and faithfully depicts one of the houses containing Black Hamburgh in the condition I saw it.

ST. MARTIN'S, NEAR CHRISTCHURCH.

The fruit gardens here are owned by Messrs. Ross and Leighton; who seem to take a delight in doing everything thoroughly well. The vineries are numerous and all have span-roofs, and are substantially built. Once inside the houses, it is easily to be seen they are managed by a master hand. The vines are all grown on the single rod system, planted 3 feet apart and closely pruned to short spurs regularly placed on each side of the rod. They were vigorous, and carrying heavy crops of handsome bunches of well-coloured, highly-finished Grapes. Messrs. Ross and Leighton apparently adopt the system of devoting one house to one variety.

Black Hamburghs were in splendid condition, also Golden Queen, which here as at Otahuhu and Mangere, were finishing in a

clear, golden-yellow colour. The house devoted to Gros Guillaume was a wonderful exhibition of this usually shy-bearing variety. Each rod produces from 12 to 16 bunches of from 3 lbs. to 4 lbs., compactly set with berries of large size and jet black in colour. Here, too, the roots have an unlimited run in warm, friable soil. Mr. Leighton is a pupil of Mr. Hunter, late gardener at Lambton Castle, Durham, and the vineries and vines show unmistakable signs of his previous experience in those vineries at Lambton in its palmy days of Grape-growing some 30 years ago.

In summing up the cause of such clean, healthy, vigorous vines, and wonderful crops of highly-coloured Grapes to be seen everywhere in the New Dominion, I attribute it more than anything else to the clear, warm atmosphere and the maiden, loamy soil, coupled with constant, careful attention by skilful cultivators. *J. McIndoe, V.M.H.*

FASCIATION IN A HOLLY.

OUR illustration, fig. 24, portrays a somewhat unusually fine example of a fasciated branch of Holly, which we received from Mr. W. T. Grace, of Hampworth Gardens, Downton. The causes that bring about fasciation are obscure, and would form a promising subject for further investigation. Sometimes the peculiarity can be induced to appear in individual plants as the result of over-feeding, and it is not infrequently supposed to be directly traceable to this cause. But a little reflection will show that the stimulus given by rich nutriment only serves as the means of causing a tendency already present in the particular plant to materialise. The fact that only an individual here and there of a number of plants grown under similar conditions exhibits the character in question at once proves that the cause is deeply seated in the plant itself, and is not attributable solely to the effects of overfeeding. Whilst in Lilies, Tropæolums, Thistles, &c., comparatively few individuals are thus affected, there are others, e.g., Celosia cristata, some varieties of Sedum, &c., in which it occurs in a considerable proportion of the offspring of every generation. The investigations of De Vries seem to indicate that the tendency to fasciation may be regarded, from the point of view of heredity, as being analogous to that which causes some plants, e.g., Stocks, to throw out a certain percentage of double-flowering individuals in each generation. But in these potentially fasciated individuals the property of fasciation may lie dormant, unless the stimulus of abundant nutrition calls it out. This proximate dependence on excessive feeding has led many persons to overlook the much more important fact that the only real function of the food in the matter is to make the plant show what it already can do, and not to impress upon it a new character. It seems not unlikely that much of the improvement in our ordinary vegetables, consequent on intensive cultivation, may primarily be attributed to similar causes.

In the fasciated stem of our specimen the pith has undergone a considerable relative increase, and constitutes about three-quarters of the cross-sectional area of the stem in the upper banded portion. It might have been expected that the flattened expansion would have assumed the histological character proper to the leaf, that is to say, the green chlorophyll-containing cells might have shown some modification in the direction of producing palisade parenchyma. Such is, however, not the case, and the cortex in every respect, save in its contour, resembles that of the normal young branch, and, like the latter, it forms a layer of cork from its peripheral cells.

FORESTRY.

LARCH APHIS AND BLISTER.

BE the connection between Larch aphis and disease what it may, it is to prevention, not the cure, of either or both that attention must be directed. Neither the aphis nor the fungus causing the blister is a new organism. The fungus, Dasyscypha calycina, has been proved to have existed in the natural Larch forests of central Europe long before its ravages attracted attention in Britain. As for the aphis, I do not know the facts about its distribution, but I can remember its presence in South-west Scotland many years before the Larch disease made its appearance.

FIG. 24.—FASCIATION IN SHOOT OF HOLLY.

Mr. Simpson contributes little or nothing (p. 22) to diagnosis by the one example which he says "will suffice." He does not give a single detail of the Dumfriesshire Larch wood in which the disease appeared suddenly and universally, except that it stands on a hillside. Of the soil, aspect, age of trees, distance of planting, he tells us nothing; only that during a very dry summer the trees were badly infested with aphis, and that the disease broke out subsequently. There is nothing in this sequence to warrant the assumption of cause and effect. Rather does the sudden exuberance of both parasites, animal and fungoid, suggest a common predisposing agency namely, lowered vitality in the trees. No phenomenon in biology is more familiar, though few may be so difficult to explain, than the manner in which the vigour and fecundity of parasites are stimulated in proportion to the impaired vitality of the host. In the case of these Dumfriesshire Larches, assuming that their vitality had been impaired, either by the dry summer taking effect upon trees planted in pure forest, which is unnatural to the European Larch, or by some other agency, the parasites already present among them would receive a simultaneous stimulus to develop and propagate. The aphides would attract attention first, pullulating in millions, like lice on an ill-nourished animal, but the blisters caused by the fungus would not be apparent before the lapse of two or three seasons. Were the European Larch such a vulnerable creature as to be incapable of sustaining with safety any lesion of bark or fracture of branch, it would be no tree for British woodlands. But it has a century and a half of good service to its credit, and we have daily evidence that Larches may be severely wounded, yet remain perfectly healthy, repairing the damage even when in close company with others suffering from Dasyscypha. The source of the disease lies deeper than branch or bark; the nidus is provided through an impaired constitution. True, the fungus obtains access through wounds, but if the constitution of the tree is vigorous, it will sustain a moderate population of aphides without much detriment, and either reject, or severely localise, the fungus.

The vitality of young Larches may be, too often is, impaired by causes within the planter's control. I beg to suggest the following as the commonest and most easily preventible conditions predisposing to disease:—

(1) Mismanagement of seedlings; lining off in a trench cut too shallow to allow the roots to be fully extended downwards.

(2) Allowing the rootlets to dry up during transport from distant nurseries, or in moving trees from the home nursery to the planting ground, especially during the parching weather of March.

(3) Careless arrangement of the roots in planting, especially when notching is the method employed.

(4) Planting too deep, which causes fresh rootlets to be thrown out from the collar.

(5) Allowing grass, the worst enemy of newly-planted trees, to throttle the young plants during two or three summers after planting. The luxuriance of ground herbage in our humid climate may be held accountable for the greater virulence of Larch disease in Britain as compared with Continental forests.

(6) Planting European Larch pure, a condition in which, unlike the Japanese Larch, it is hardly ever found in a wild state.

The Japanese Larch (L. leptolepis), on the other hand, is described as growing naturally in pure forest. The amazing vigour of this species enables it to overcome many of the dangers that lie in wait for the European Larch, notably that of rank grass and herbage. It is true that Dasycypha has been found upon a Japanese Larch here and there, but the vitality of the species is so great that, if it is maintained as the trees approach maturity, there is little cause to fear that they will succumb to blister. Within 300 yards of where I sit writing, there are small patches of the fungus both on Corsican Pine and Scots Pine, but the vitality of these trees is so great that it can make no progress. If, however, a bad outbreak of sawfly should lower that vitality by destroying the foliage in successive seasons, I should anticipate that Dasycypha would go ahead. Sawfly, be it observed, cannot be reckoned a parasite in the same sense as aphides. It is an external foe, like rabbits, locusts, or white butterflies, its abundance, greater or less, being independent of the morbid or healthy condition of the plant attacked. *Herbert Maxwell, Monreith, January 13.*

WEATHER AT ROTHAMSTED IN 1907.

FROM the meteorological records of the Rothamsted Experimental Station, Hertfordshire, we learn that the year 1907 was characterised by a deficiency of rain and a deficiency of bright sunshine; upon the whole, the weather has shown a year of gloom. There were seven months recording a low rainfall, and five months giving an excess. As regards temperature, there were five months below average and seven months above average, the great feature of the year being its low night temperatures.

The bright sunshine showed six months above and six months below the average records.

March was noted for its abnormally warm sunny days. It was the month of highest sunshine for the whole year, a total of 206.4 hours being recorded, which is 92.5 hours in excess of the average amount for this neighbourhood. The large quantity of bright sunshine for March caused the ground at 1 foot deep to be 5° warmer than is usual for the time of year, which was very beneficial for the germination of small seeds in the garden and for spring-sown Corn.

April was the wettest month that has occurred at Rothamsted for the past 25 years. There were 17 rainy days and three slight falls of snow. The total rainfall for the year was 27.4 inches, showing a deficiency of seven-tenths of an inch compared with the average at Rothamsted extending over the past 54 years. Although the total rainfall was less than the average, the actual number of rainy days for the year was 21 in excess of the usual number, with 10 slight falls of snow.

April, June, and October were the months of greatest rainfall, over 11 inches being measured during these three months. September was the month of largest deficiency of rain, there being a falling off from the average of nearly 170 tons of water on each acre of land.

The mean temperature for the whole year was 47.9°, which is exactly the average record at Rothamsted. December, the last month of the year, was noted for its extreme mildness, the mean temperature being 2.2° above the normal. There were several days when the warmth was as great as during several days of May. In the flower gardens around here were to be seen many blooms of Roses, Pansies, Violets, and Primulas.

The bright sunshine for the year amounted to 1,557 hours, being 49 hours deficient. The first three months of the year gave 123 hours of bright sunshine in excess; the next five months, which included the usual growing period of our field and garden crops, recorded 191 hours of sunshine less than the average for the district.

June weather was generally showery, cold, and dull; both grass and grain crops were exceedingly backward. The ears of Corn were a considerable time in pushing themselves free of the sheath, which is always a sure indication of a low yield of grain per acre. The blooming time of the grain crops was about a fortnight later than is usual at Rothamsted.

Hay harvest did not commence until the middle of July, and in fact there is but little really good well-cured hay to be found from this year's crop. As one travelled about the country it was no unusual thing to see a field of meadow hay still uncarried, bleached and sodden with rain, in the second week of August.

September, with its glorious weather, seemed to come, as it were, to atone for the shortcomings of the months immediately preceding, and registered 185 hours of bright sunshine, or 24 hours in excess of the average, and the mean temperature was 57.6°, showing 1.8° above average. The Corn harvest did not become general until the middle of September, being about three weeks later than usual.

October was a month of excessive rainfall and over average temperature, but deficient sunshine. Both November and December gave more than normal temperature and over average sunshine.

The following table shows the rainfall of each month for the past year of 1907 at Rothamsted, with the average amount of rainfall for each month of the previous 54 years, and the difference of 1907 above or below the average record:—

RAINFALL AT ROTHAMSTED, HERTS.

Months.	Rainfall 1907.	Average Rainfall of 54 years.	1907 Above or below the average (1).
	Inches.	Inches.	Inches.
January	1·25	2·39	- 1·14
February	1·18	1·81	- 0·63
March	1·31	1·84	- 0·53
April	2·83	1·83	+ 1·01
May	2·40	2·19	+ 0·21
June	2·61	2·41	+ 0·20
July	2·21	2·52	- 0·31
August	1·80	2·65	- 0·85
September	0·78	2·46	- 1·68
October	1·89	3·44	- 1·55
November	2·44	2·60	- 0·16
December	3·10	2·30	+ 1·10
Yearly Total	27·41	28·14	- 0·73

(1) The sign in the last column (+) signifies above the average, and the sign (-) below the average.

The rain-gauge, which is one-thousandth part of an acre in dimension, stands 2 feet above the surface of the ground, and is about 420 feet above sea-level.

The above data shows a total rainfall of nearly 27½ inches, against an average for the previous 54 years of slightly over 28 inches, being three-quarters of an inch deficient. Calculating these figures up to the acre, we find that during the whole year 2,768 tons of water has fallen on each acre of land, and if it had not been for the excessive rainfall of October and December, which recorded 828 tons of water in excess of the average, the underground water supply of this district would have been abnormally low, resulting very probably in a water panic.

The next table shows the mean temperature in the shade for each month of the year 1907, with the excess or deficiency at the Rothamsted station during the past 29 years; also the number of hours of bright sunshine recorded for each month, and the number of hours above or below the average record.

MEAN TEMPERATURE AND BRIGHT SUNSHINE AT ROTHAMSTED, HERTS, FOR EACH MONTH OF THE YEAR 1907.

Months.	Mean Temperature.		Bright Sunshine.	
	1907.	Above or below average.	1907.	Above or below Average.
	Degrees.	Degrees.	Hours.	Hours.
January	37·0	+ 0·2	66·4	+ 15·4
February	36·3	— 2·0	85·2	+ 15·3
March	42·5	— 1·6	206·4	+ 92·5
April	45·8	— 0·2	143·1	— 26·3
May	51·2	— 0·1	164·4	— 31·5
June	55·5	— 1·9	160·2	— 13·2
July	57·0	— 4·0	170·6	— 57·9
August	58·4	— 1·6	174·5	— 32·0
September	57·6	+ 1·8	185·1	+ 24·2
October	49·2	+ 1·2	97·3	- 8·5
November	43·6	— 1·1	58·1	— 0·8
December	39·9	+ 2·2	45·8	- 2·3
For the year	47·9	0	1557·1	- 48·9

The mean temperature for the year was 47·9°, being exactly the average record.

Each of the four last months were warmer than the average, although the bright sunshine was but little above average, except in the case of September.

The bright sunshine was 326 hours less than was recorded in 1906. During the present year the sun shone but 4 hours 16 minutes on each day throughout the year, against 5 hours per day in 1906. *J. J. Willis, Harpenden.*

PLANT NOTES.

SAINTPAULIA IONANTHA.

I do not know of any plant which gives better returns for the small amount of labour needed to bring it to perfection than does this little stove flowering species. If well grown, it forms a mass of the loveliest blue colour, from 1 foot to 18 inches in diameter, and if staged lightly at the cool end of the stove, and interspersed with some silvery-foliaged plants, as Caladium argyrites or Dracæna Sanderæ, it will form an object of great beauty. If the dead flowers be picked off occasionally, the plants will continue to develop an abundance of bloom the whole season through. Early in February, from healthy plants, sever good sound leaves with stalks of about 3 inches long, and insert the petioles in light, sandy soil; or, if pressed for room, as is often the case at that season of the year, insert them in the material beneath the plant stages, in a perpendicular position, as if the leaves are allowed to rest on the rooting material they will damp off. As soon as they have formed small crowns with a few leaves, remove the old leaf, and pot the little plants into 3-inch pots, using a compost of loam and leaf soil in equal parts, with enough sand to keep the whole porous. Place them on a shelf as near to the roof-glass as possible, to induce them to make close, compact plants. As soon as these pots become filled with roots, transfer the plants to 5-inch pots, using compost similar to the last,

but with an addition of some good fertiliser at the rate of a 4-inch potful to a barrowful of soil. In most cases 5-inch pots may be considered large enough for the plants to flower in, and in these they will form dense plants 15 or more inches through them, in a period of six or eight months. If still larger plants are required, transfer them into 8-inch pots, using compost and fertiliser as before, and they will quickly make lovely specimens quite 18 inches through, and amply repay any extra time and labour expended on them. Great care must be exercised after each potting that the plants are not over-watered until the pots have become well filled with roots. After this stage they must on no account be allowed to become dry at any time, but should be assisted with slight top-dressings, or with diluted liquid manure applied at alternate waterings. Plants raised from seed do not give as good results as those raised from leaves. *D. Wilmshurst, Coronation Cottage, Hurstmonceux, Sussex.*

SPECIES OF PRIMULA AND P. HYBRIDS FOR WINTER FLOWERING.

YELLOW-FLOWERED Primulas, which bloom abundantly in the winter months, are plants which have great value as cut flowers, and the best of these are P. floribunda, P. f. Isabellina, and P. kewensis, a cross between the first named and P. verticillata, obtained in the Royal Botanical Gardens, Kew. P. floribunda has a flower stalk about 1 foot in height, and flowers arranged in a twirling manner at three stages thereon; colour, deep yellow. The leaves possess strong ribs and nerves, and are somewhat hairy. P. verticillata has lanceolate leaves of a whitish green tint, the underside covered thickly with meal. The flower stalks are stiff, mealy, and of considerable height, and the blooms arranged in stages.

The umbels are pale yellow at the base of the flowers, and the latter are of a trumpet shape. The tube is about three times as long as the diameter of the same. The flowers have a pleasant fragrance. The hybrid P. Kewensis unites the good properties of both parents, and it has strong ribbed green leaves, and the deep yellow blooms and abundant flowering habit of P. floribunda, the fine fragrance, the long, tubular flowers, and the encircling garland of leaves of P. verticillata, but the flowers are twice as large. The floral stages are arranged at from 3 to 4 inches apart, and the flowers appear almost simultaneously.

GALEGA (TEPHROSIA) GRANDIFLORA.

A BRIEF note by Mr. Adam Heydt in Moller's *Deutsche Gartner-Zeitung*, No. 44, 1907, concerning the uses to which this Papilionaceous species may be put has interest for gardeners who have conservatories and large glasshouses under their care. The plant is a tolerably strong grower, well adapted for growing in large pots or small tubs, and well cultivated plants find excellent uses in the garden, and perhaps this is a better place for it than as a pot plant. The colour of the butterfly-like blossoms is a rosy carmine. The best sort of soil for the plant is rich loam, leafmould, and as much sand as will secure porosity. The plant should be raised from seed, cuttings seldom being certain to grow. Galega Hartlandii, a rare species, is propagated in the spring by division.

NICOTIANA SANDERAE AS WINTER FLOWERER.

THIS species of Nicotiana has become in a short space of time a favourite subject for out-of-doors beds and groups in gardens in which the more or less free modes of decoration are allowed, the effects of the bright and pleasing tint of the flowers being always good if a sunny aspect is afforded them. In shady or even partially shady positions, the plant does not grow as strongly or flower so freely. As a winter-flowering species, Nicotiana is grown to a lesser degree. In the pages of a foreign contemporary, I observed recently a note on this subject, in which a correspondent gives his experience with N. Sanderiana, and shows with what facility the plant may be grown for winter blooming. The seeds should be sown in warmth in the latter half of the month of June in pans, and the seedlings pricked off into pans when large enough to be handled, and placed in an ordinary cold frame, and on reaching a few inches in height they should be transferred singly to small pots, with an occasional small shift into larger ones, till they come to the stage at which the flowering shoots appear—that is, not later than the early part of October. Should no flowering shoots appear before that date, the plants will fail to give satisfaction, as the required degree of sunshine is missing in all northern European countries. Plants cultivated in this manner will bloom continuously throughout the winter till March and April, and afford extremely fine effects. The winter temperature should be not less than 50° to 55° Fahr.

There are other methods by which this plant can be brought into bloom in the late winter months; thus, for example, the plants kept over from late spring sowing which may not have shown any blooms, may be put into a moderately warm greenhouse before they get injured by cold weather, and in February be transferred to larger pots. They soon develop flowering shoots, and when in full bloom they may be placed in the greenhouse or conservatory among the ordinary inmates, such as Primulas, Cinerarias, and various bulbous plants, and the like.

After the chief flowering season is passed, if well supplied with manure water, they soon commence to flower again in perfection. N. Sanderiana, and likewise N. affinis, exhibit varieties differing in the colours of the bloom, a circumstance adding greatly to the attractiveness of the plants. *F. M.*

DIANTHUS ARBOREUS.

OF the large number of species of Dianthus which are known in gardens, few are of shrubby habit. What is probably the giant of the genus in this respect is the subject of the present note. It has long been in cultivation in this country, but on account of its somewhat tender habit has not met with the appreciation it so richly deserves. The plant, from which the illustration at fig. 25 was prepared, is one of a number cultivated in the Royal Gardens, Kew, which withstood the winters of 1905-6 without protection in a border facing to the north-east. The severe weather in March of 1907, which was accompanied with cold northerly winds, cut all these plants down to the ground. At the time the photograph was taken (in July, 1906) the specimen illustrated was three and a half years old from a cutting, and was over 4 feet in height and about 5 feet in diameter. The habit of the whole plant reminds one of that of a large Tree Carnation. The stems are densely clothed with leaves in the lower part, the flowering portion being erect, slender, and bearing very few leaves. The leaves are opposite and decussate, linear, acute, slightly glaucous, the upper surface canaliculate, lower convex. The flowers are erect, sweetly scented, and borne in profusion in terminal corymbose heads. The calyx is ¾ inch long, forming a long slender tube, light green in colour, and covered in the lower part with numerous light green bracts. The corolla is salver-shaped, 1½ to 2 inches in diameter, and consisting of either four or five obovate, serrate, rose-coloured petals. This species should succeed well in the milder parts of these islands, where, under favourable conditions as to soil and situation, it would rapidly form a large bush. It is a native of the Grecian Archipelago, also of the island of Crete, and a good figure of the species appears in Sibthorp's *Fl. Graeca*, tab. 406. *C. P. Raphl.*

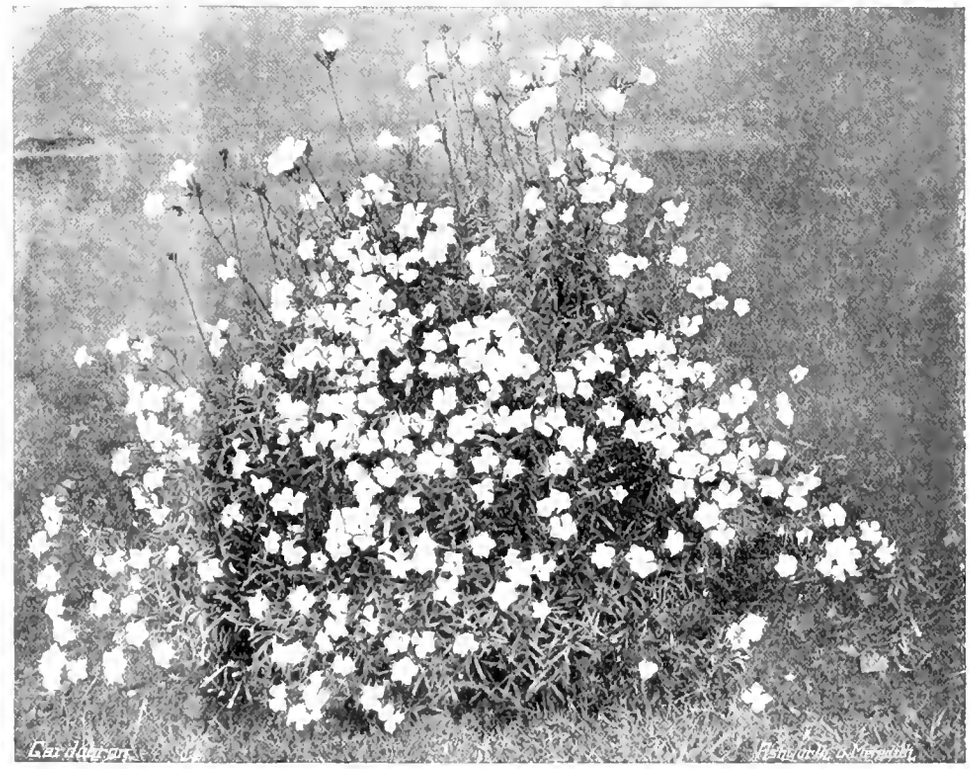

FIG. 25.—DIANTHUS ARBOREUS: FLOWERS ROSE COLOURED.

FLORISTS' FLOWERS.

THE ALPINE AURICULA.

I HAVE read the short note by *A. D.* at page 428, Vol. xliii., and I certainly did not wish to convey the impression that the edged or florist's Auricula was the only type in existence. What we may term the Alpine Auricula, for want of a more correct name, is equally important as a garden favourite. Primula pubescens is supposed to be the original species from which the so-called Alpine Auricula has been evolved, but the show or "florist's" type of Auricula has an equal claim to be termed Alpine Auricula, as it grows naturally in a similar position. For garden purposes the one is the "show" Auricula, the other the "Alpine" Auricula. The Alpine type is also divided into two classes or sections, the yellow-centred varieties and those having white or cream-coloured centres, and it is rather curious that all the white-centred varieties have purple margins of some shade or other. The important point in the colour is that it should shade off to a lighter tint at the margin.

The yellow-centred varieties possess very richly-coloured margins, crimson maroon, crimson, or shades of red; but their standard of excellence is similar to that of the white centres, and in each case the colour is lighter at the margin. The fanciers insist that the self-coloured show Auriculas should possess an unshaded edge, and the Alpines a shaded edge. The show varieties should have a dense coating of farina on the centre of the corolla, but the Alpines ought to have no farina anywhere. *A. D.* asks for "stiff erect stems, bright pleasing colours, large rounded pips, and impressive beauty." Well, I can assure *A. D.* we have all this in the Alpine Auricula. Of course, there is still ample room for improvement, but improvement is going on every season. Last season notable additions were made to the white ground section. The best of them was exhibited at the National Auricula Society's exhibition in London last season, and was named Martin M. Smith by request; it not only obtained the Award of Merit of the Royal Horticultural Society, but also a First-Class Certificate of the National Auricula Society. Moreover, it was awarded "Premium" as the best Alpine Auricula in the exhibition in 1907.

Other very fine and distinct varieties were exhibited, showing an all-round advance on the year's work. One named Argus, raised by Mr. J. J. Keen, of Southampton, was well shown and greatly admired. It has been in cultivation for several seasons; it is also included in the varieties with white centres.

The *Gardeners' Chronicle* usually gives a list of the certificated florists' flowers, and it will be seen that there is a good record of new Auriculas of the Alpine section. This type of Auricula is well adapted for hardy border culture, and there are numerous very beautiful varieties to be obtained at a cheap rate; but the Auricula is not a plant that grows rapidly, and from the offset stage until the plant is fully developed it takes about 18 months. I am writing now of the choice varieties, such as would be recognised at the Auricula Society's exhibition. This section is well adapted for culture in the open garden, and the best position for them is in the rock-garden or the front row of herbaceous borders, either as single specimens or planted in masses; they soon become established, and will grow and increase freely for several seasons if left undisturbed. Six to a dozen plants of one variety planted 6 to 9 inches asunder in a clump or mass make a striking object in nooks in the rock-garden; and the plants always thrive better if set out on the north or shady side of a piece of rock or stone. The Auricula does not take kindly to a sunny position, and if the heat of the sun is aggravated by the heat thrown off by heated rock or stone the plants remain small, and produce but small trusses of bloom. A generous soil is required, and a compost inclined to clay suits the plants better than a sandy soil; if the soil is light with a gravel subsoil it is easy to dig out the natural soil and replace it with a few spadefuls of a suitable compost. This ought not to be thought too much trouble, for every lover of a garden knows that no garden in itself contains the best kind of soil for every plant he desires to cultivate, and if success is to be attained it must be by providing the soil which each species or variety requires. Some plants will not thrive in light, sandy soil, but will succeed well on a clayey loam; others require fibrous peat; some do well on loam over chalk; and the enthusiastic amateur will take care to provide each plant with the special compost suitable to its needs.

Such a garden, provided with the soil necessary for the various plants, was that owned by the late Mr. George F. Wilson at Weybridge. I well remember being shown round his garden two or three years after Lilium auratum was introduced, and amongst other treasures of the family of Lilium I measured a plant of L. auratum 11 feet in height. Mr. Wilson remarked that it ought to be 11 feet high, as it had 11 feet in depth of good compost to grow into. Other handsome specimens of this and other Lilies were provided with large beer or paraffin casks sunk into the ground to the rims, and these were filled with the special compost best adapted to their needs; the same careful method was adopted at Wisley.

Miss Willmott's garden at Warley Place is the best illustration of a garden known to me where the requirements of the plants are carefully provided for. Of course, very few can hope to be so fortunate, but everyone can have a garden full of well-grown plants if they are careful to define its limits. It is surely better to have 50 plants in a thriving condition than 500 struggling for existence in unsuitable soil or unfavourable conditions.

These remarks may seem to be a digression, but I want to point out that, in order to grow the Auricula well, some attention must be given to its requirements, and if this be done it is one of the easiest plants to grow either in the open garden or under glass. Some amateurs may say—But why grow plants under glass if they will grow and thrive out of doors? The only reply to this is that the Auricula is a favourite flower, and the beauty of the flowers is more fully developed under glass, where they are protected from the uncertain climate of Britain in the month of April. The cultivation of the Auricula in flower-pots is very similar to that of the show Auricula; moreover, many persons prefer the Alpine varieties in the first instance, but in time they usually transfer their appreciation to the show varieties. It is much easier to get up a stock of the Alpine section, but in both there is a considerable difference in the number of off-sets produced from varieties in the same group. Take, for instance, the white-edged Acme; in, say, six years, it might be possible to obtain 80 or 100 plants from one, but the white-edged John Simonite has not given me one off-set in six years. I do not know any Alpine variety that is anything like so slow of increase. The following is a selection of the best Alpine Auriculas known to me, which can be supplied by dealers in these plants:—

Admiral, gold centre. **Argus,** white, claret colour, shading to a pale tint. **Boadicea,** centre cream coloured, with purple margin. **Byron,** bronzy yellow, with gold centre. **Dean Hole,** centre deep yellow, with maroon-crimson margin. **Duke of York,** very similar in colour to the last one, but a more refined flower. **Firefly,** centre rich yellow, with crimson shaded margin. **Ganymede,** centre cream coloured, with reddish brown margin. **General Buller,** of correct form, possessing gold centre, and reddish crimson margin. **Melanie,** centre white, and blue purple margin. **Mrs. Markham,** centre gold coloured, with maroon and red margin: **Perfection,** of large handsome form, crimson and gold; **Rosy Morn,** bronzy yellow, with gold centre; **Teviotdale,** one of the best white-centred varieties. **The Bride,** distinct shade of rosy apricot, with gold centre. **Thetis,** centre cream coloured, with maroon purple margin; **Uranie,** centre yellow, with deep red margin. In every instance the colour is deepest at the yellow disc, shading off to the lightest tint at the margin of the corolla. *J. Douglas.*

NOTICES OF BOOKS.

*THE PLANTS OF THE BIBLE.

THIS little book is a useful accompaniment to the *Bible Herbarium* and *Palestine Herbarium* issued by the American Colony. The majority of the plants briefly described are quite correct, but a good many plants are doubtful, so that it does not do always to speak positively, *e.g.*, the author writes of "Spices" that the R.V. gives "gum tragacanth," "correctly, no doubt." But four other Hebrew words are rendered "Spices," all implying a "sweet odour," while that in Genesis, referred to, means "made into a powder." Gum tragacanth has no scent. It flakes without making a powder. The Almug I make out to be the Yew, from various reasons given in my *Plants of the Bible* (Masters). The Sandal wood being a tropical tree is less likely, as the Almug was seemingly some tree of Lebanon. Aloes (Aloe vulgaris) is not the Lign-aloes, but was probably used, like Galbanum, for fixing the more evanescent scents. Apple appears to be the Quince, as being "scented." The Christ-thorn was more probably Paliurus, as a very common shrub, with very flexible and spiny branches, and therefore suitable for twisting into a crown. "Husks" were the carob, as the Greek word implies, but also the fruit that the Baptist ate; the error appears to have arisen from a transcriber substituting a Hebrew G for the R in *choreb*, which turns the word from "carob" to a "locust." As our Lord used the word *krinon*, the common Greek word for Lily, there does not appear to be any good reason to imply that He meant Anemone; *krinon* was not used in any indefinite sense. "Rie" is referred to *Vicia ervilea*, because the Arabic *Kirsenni* is supposed to be the same as the Hebrew *Kussemeth*, but "spelt" is much more probable. The above are some of the more doubtful interpretations, but the little book will be found useful to those interested in the plants of the Bible. *George Henslow.*

†MUTATIONS, VARIATIONS, AND RELATIONSHIPS OF THE ŒNOTHERAS.

THE work of De Vries on the origin of species in the Evening Primrose, Œnothera Lamarckiana, deserves the attention of the practical gardener, no less than that of the student of evolution. De Vries is the first to have caught a plant in the act of giving rise to new species.

One or two of our more go-ahead seed-men and plant breeders have been quick to see that they can gather from a study of De Vries' work information of incalculable value to them. And the time will shortly be when no breeder of plants can afford to dispense with an intimate acquaintance with this class of facts.

It is now about 20 years since De Vries first found Œnothera Lamarckiana on a disused Potato field at Hilversum, near Amsterdam, and started the famous series of pedigree cultures which enabled him to study in detail the origin of over a dozen new species.

The interest aroused in the Evening Primrose itself by this work on it has, perhaps naturally,

* Prepared by the American Colony (pamphlet 6 by 4 inches, pp. 48). Vester & Co., Jerusalem, Palestine. [illegible]

† By D. T. Macdougal, A. M. Vail, and G. H. Shull. Published by the Carnegie Institution of Washington.

taken its most active form in America, its native home. The book before us—the outcome of work carried out in the Botanical Garden at New York, the station for experimental evolution at Cold Spring Harbour, Long Island, and in the Desert Botanical Laboratory at Tucson, Arizona—is valuable both to the specialist and to the novice; to the former on account of the wealth of new material which it contains; to the latter, because some of the illustrations of the newly-arisen species are far the best that have been published so far.

But the book is primarily for the specialist. It pre-supposes a familiarity with de Vries' results, which can be best obtained from *Species and Varieties: their Origin by Mutation* (Open Court Publishing Co.), pending the appearance of the translation of *Die Mutations Theorie*, the first volume of which is expected this year.

[1] LES ARBUSTES D'ORNAMENT DE PLEINE TERRE.

THIS little book gives in a compendious form a useful description of the chief ornamental shrubs in cultivation. An introductory chapter deals briefly with the cultivation and arrangement of the plants in the garden. The figures that accompany the text are unequal, some being decidedly good, whilst others, especially the half-tone reproductions, are poor in quality. The book deserves commendation, and the name of the author, who is the head of the experimental cultural establishment of Messrs. Vilmorin-Andrieux & Co., is a sufficient guarantee of the accuracy of the information it contains.

The Week's Work.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

Cordylines (*Dracænas*).—Those plants that have become bare of leaves at the base should be put aside for stock purposes. Cut off the tops if these are in good condition, and insert them in sandy soil in small pots. Then strip the rest of the leaves off the stem and place the plants in a light part of the house. After the elapse of a few weeks the dormant eyes will be showing, when a small piece of the stem about an inch long with each eye should be cut straight across; if there is more than one eye showing on the piece of stem, the others should be cut off. Insert the pieces in an upright position in small pots in a light sandy soil and place them in a good bottom heat; there will soon appear a fine young shoot from each eye. This is by far the best manner of raising young Dracænas, for these raised in this way make the best of plants and last for a very long period without showing flower. As soon as the next set of eyes on the old stems appear, treat them likewise. The old stock keeps pushing up the eyes and seldom do any of these fail to start when treated this way, but if all the stem is cut up at once very often the eyes lowest down the stem fail to move. Great care should be exercised in watering these before the young shoot appears, as too much moisture at this stage is liable to cause them to rot. Repot the little plants as soon as the roots reach the side of the pot.

Freesias that are showing bloom should be given weak liquid manure each time they are watered. Place four neat thin stakes in a 6-inch pot, and a piece of raffia tape tied round them will answer admirably for keeping the flowers in an upright position. The plants should be kept in a position near to the glass in a cool house.

Cinerarias.—The earliest of these plants will be coming into bloom and should be kept as cool as possible, ventilating the house on every favourable occasion. If green fly makes it appearance, fumigate the house at once or the blooms will be crippled and the plants spoiled. The soil being more or less exhausted, a liberal supply of some favourite artifical manure should be given, as Cinerarias are gross-feeding plants; and strength is required in the plant to develop all the flower-spikes possible.

Begonia Gloire de Sceaux is now flowering freely and should be kept in a rather dry atmosphere of intermediate temperature. The fallen petals should not be allowed to lay on the leaves of the plant, as these are liable to damp very quickly. This Begonia requires liberal feeding all through the spring, but the manure water must be applied in a diluted condition.

Rhododendron Nobleanum.—This Rhododendron (see fig. in *Gardeners' Chronicle*, March 14, 1896) will now be appreciated among the best forced plants for the decoration of the mansion, and conservatory. The plants should be removed from the forcing house to a cooler atmosphere as soon as the buds show signs of bursting.

Chrysanthemums for large blooms.—Cuttings inserted early last month should now be rooted. Place them on a shelf near the glass in a cool house. A cold vinery or Peach house affords as good a position as can be got for them at this stage. Place a few small tiessels over the hot-water pipes and a couple of boards about a foot wide, covered with an inch of ashes, securing that the boards are about 2 feet from the glass; the plants will then grow slowly and gain strength. The ashes should always be kept damp, as very little water can be given the plants at this stage, or they would get what is commonly called the "yellows." Do not ventilate from the front or bottom ventilators unless on very mild days, and then only a little at a time. If there is bright sunshine, slightly spray the plants overhead with the syringe at about 2 o'clock in the afternoon.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Heudre, Monmouthshire.

Cucumbers.—It is only by skilful management, even if the means are favourable, that a regular supply of Cucumbers can be maintained throughout the winter, but as the days lengthen growth will be more active, and the plants will acquire increased fruitfulness. Remove any weak or superfluous growths and stop the strong ones, but not sufficient at one time to cause a severe check to the plants. Thin out the fruits at an early stage of growth. At night an atmospheric temperature of from 65° to 70° should be preserved, rising a few degrees by day, in accordance with weather. Atmospheric moisture should be promoted by damping the surfaces in the house, and during bright weather the plants should be subjected to spraying. Encourage the roots by affording them periodical top-dressings of a compost consisting of moderately rough fibrous loam, lightened with broken-up horse droppings and flaky leaf soil, to which a little bone meal or some similar fertiliser may be added. Attend carefully to the matter of watering, using only tepid water for this purpose or for spraying the plants. Sow seeds for raising a further batch of plants, using pots measuring 3 inches in diameter; cover them with a piece of glass, and plunge them in a hot-bed having a temperature of 80°. As soon as the plants are through the soil, place them in a position near to the glass, and when well rooted, and each plant has made a rough leaf, they may be planted in their permanent quarters. For planting at this season we select a lean-to house, provided with a trellis arranged near the glass, and plant singly upon warm hillocks of compost placed 4 feet apart, upon a bed of tree leaves, with hot water pipes beneath.

Tomatos.—At the end of the present month seeds should be sown for raising the chief summer crop. Take shallow pans, and after the provision of means of drainage, make them two-thirds full with a fine sandy compost. Place the seeds at about 1 inch apart, lightly covering them with compost, and protect them with sheets of glass. As soon as the plants appear, remove the glass and place the pans upon a shelf in a house in which the heat at night will be maintained at about 55° or 60°. As soon as they are large enough to handle, carefully lift them and pot them in 3-inch pots. Carefully ventilate the structure in mild weather, and maintain a moderately low temperature. When the plants have filled the pot with roots, repot them into others, 6 inches in diameter, making the compost—loam lightly mixed with leaf soil and coarse sand sufficiently firm to promote sturdy growth. Excellent varieties include Sunrise and Frogmore Prolific (red) and Golden Jubilee (yellow). Fruiting plants should be afforded heat that will not fall below 55° or 60° at night, and may rise 5° or even 10° by day when the weather is mild. Extra care must be exercised in the giving of water, and stimulants at this season, more especially if the plants are planted out, instead of being in pots, as is the best method to adopt for winter fruiting plants. Admit air as opportunity offers, and attend to the pollinating of the blossoms at mid-day.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Cherries.—If the winter pruning and training of Cherry trees has not already been done, this work should be given attention at the first opportunity. The main pruning of dessert Cherries should always be done as far as possible in the summer. Trees that were given proper attention in that season will now only require to have most of the remaining spurs shortened to two buds. Dessert Cherries should never be cultivated in very rich soils or they will grow too vigorously, and the consequent severe cutting be conducive to "gumming." If the roots are in a good condition, the kind of soil in a particular garden should afford the best guide as to when and how to apply stimulants. Trees growing in poor soils often produce more fruit buds than those growing in richer soils; such trees should be treated liberally with stimulants at any season of the year, but similar feeding would be very injurious to trees growing in richer land.

Morello Cherries.—These trees require different treatment in regard to pruning, as they bear on shoots made in the preceding year. Remove any old branches that can be spared and all misplaced growths and weak shoots, leaving as many of the young growths as can conveniently be laid-in at distances of about 4 inches apart. As soon as the pruning and nailing is completed, the trees should be thoroughly syringed with some effective insecticide, choosing a fine day for carrying out the work, so that the trees may have a chance of becoming quite dry before night.

Apricots.—The bloom-buds of Apricots are the first of all fruits to expand, and a very little mild weather causes them to show signs of bursting. The pruning and nailing of these trees should be given attention as early in the year as convenient. The bloom-buds are also very easily injured by frost, and some kind of protection should be in readiness to place over the trees as soon as the buds show signs of requiring it. The pruning of Apricot trees should, as far as possible, be carried out during the growing season, and the winter pruning will then not be of a very severe character. Remove any shoots that were overlooked in the autumn, and any ill-placed spurs, laying in any young shoots for which there is ample space. Very strong shoots on young trees should be left their entire length, training them at least 1 foot apart, as, by cutting them hard back, "gumming" would be likely to result. By careful pinching in the spring, these shoots can soon be induced to produce plenty of spurs.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Plants in frames.—After the cold weather already experienced plants in unheated frames, such as Echeverias, Veronicas, Gaillardias, Pentstemons, Campanulas, Violas, Salvia Pitcheri, &c., should be cleansed of all dead leaves, &c., and air should be admitted to the frame on every favourable opportunity. The shoots of Pentstemons and Violas may be pinched, but not those of the Veronicas, these latter flowering much earlier and freer if the centre stem is left intact.

Sweet Peas should now be sown in 4-inch pots placed in cold frames. Give attention to the plants raised from autumn-sown seeds in the open. Birds and insects very often being troublesome at this season, it may be necessary to apply nets, and dustings of lime or soot. Autumn-sown Sweet Peas generally compensate for the little extra care required in their cultivation; they yield long-stemmed, large, richly-coloured flowers. If the seeds are sown thickly in the autumn, the plants may be transplanted in early spring without suffering any serious check to growth.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Diseases and pests.—When Orchids are cultivated in the best conditions they are less liable to the various diseases which attack them. The fleshy pseudo-bulbs and leaves of many kinds are nevertheless sometimes attacked by the disease known as "spot." When once plants are badly affected with this malady, it is difficult for the cultivator to restore them to health, and if he succeeds, it will still need several years' good treatment to efface all traces of that which perhaps was contracted in one season. The principal causes of disease amongst Orchids are: bad air, extremes of atmospheric temperature, insufficient or excessive applications of water at the roots, overfeeding of such plants that are assisted with manures, and last, but not least, the evils that result from dirt and parasites. Scales are the worst enemy, and difficult to eradicate, as they conceal themselves under the outer sheathing of the pseudo-bulbs. The kind like a stock seed is very troublesome, as it not only attacks the leaves, bulbs, and flowers, but also the roots. It increases rapidly, and if remedial measures are not immediately taken, it will quickly spread over a collection, especially if ants are plentiful, for they carry it from place to place for food. Fortunately, it is far more easily got rid of than other kinds, as it is the only kind of scale that is injured by fumigation, and again it does not seek the undersides of the leaves so much as other insects, so that its work is nearly always in sight. For removing the small white and brown scales that affect Ærides, Vandas, Cymbidiums, Cattleyas, &c., spraying with some safe insecticide must be employed. Here we use a kind known as Mitchell's Reliable Insecticide with satisfactory results. Thrips and green fly give trouble sometimes at this season, but frequent fumigations with a safe vaporising compound will keep these in check. Orchids have other enemies in the shape of slugs, snails, wood lice, and cockroaches. Lettuce leaves, sliced Potatos and Carrots, and bran in small saucers, placed about the houses can be used as traps, and with the aid of a lamp at night, diligent search amongst the plants will make it possible to keep down these pests.

Calanthes.—There are many very handsome varieties and hybrids of the deciduous section of Calanthes, but owing to their rarity they are not generally known. C. vestita and C. Veitchii are kinds most extensively grown for decorative purposes, the latter being one of the most popular hybrid Orchids ever raised. These are cultivated in most large gardens, and even in places where Orchids are not made a speciality Calanthes are often found in the most satisfactory condition. I do not advise, as the plants go out of flower, turning the pseudo-bulbs out of the pots, entirely divesting the roots of all soil and storing them thickly in boxes, unless for exigencies of space, as I believe they are better left alone until they start into growth. A common mistake often made with these plants is that of leaving them about in cold, draughty places, in conservatories or elsewhere. The pseudo-bulbs so treated never start so well, nor do they produce such fine growth as others that are kept quite dry in an atmosphere having a minimum temperature of 55 degrees. In such conditions the plants obtain the thorough and complete rest that is so necessary to their well-being, yet their "eyes" are not chilled or checked, and, therefore, start away vigorously in spring.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Peas.—Autumn-sown Peas which are intended to produce an early supply under glass, whether in pots, boxes, or sown in borders, should receive abundance of air whenever the conditions of the weather are favourable. Never apply fire-heat except in the severest of weather; Peas at all times suffer if subjected to hard forcing. Apply neat, twiggy sticks immediately growth commences in order to ensure the plants being kept in an upright position, and add a surface dressing when the plants are from 3 to 4 inches in height. Make further sowings under glass either in pots, boxes, or the dwarfer kinds in pits or frames. There are so many new and improved varieties, both as regards cropping and edible qualities, that it is almost a waste of means to cultivate the old white-seeded sorts. Gradus, Early Giant, Edwin Beckett, and Early Morn may be classed among the very best for early cropping, and are but a day or two later than those which are in every way inferior.

Broad Beans.—Though not generally grown under glass, these are quite worthy of anyone's attention. Seeds may be sown at any time during the present month, placing four seeds in 8 or 10-inch pots, which should be half filled with soil, adding more soil when the plants have reached the top of the pots. Place the pots in moderate heat until the seedlings appear, after which subject them to much the same treatment as Peas. Afford the plants an abundance of air when in flower and pinch out the points when a free set has been assured. Beans so cultivated will be found to be ready for use several weeks before those in the open. Aquadulce and Leviathan are both excellent varieties for pot-culture.

Artichokes (Jerusalem).—The whole of these may now be lifted whenever the weather is favourable, and if it is intended to grow them on the same ground next season, trench the soil and work in amongst it a liberal addition of farmyard manure. This crop will do remarkably well on the same site for many years if this rule is observed each season. The smaller tubers may be planted immediately the work is completed. The white-skinned variety is much to be preferred from every point of view to the old red kind.

Rhubarb.—When it is intended to make a new plantation, the earlier it is carried out in the year, assuming the weather is favourable, the better. The ground should be deeply trenched, applying abundance of manure, and land which is of a stiff, retentive nature should be given liberal dressings of such materials as mortar-rubble, road-sand, and wood-ashes. Among the very best sorts are Hobday's Giant and The Sutton, both thoroughly distinct and worthy a place in any garden. Rhubarb is easily increased by division of the stools. Little difficulty will now be experienced in forcing Rhubarb in the open garden. Place suitable pots or tubs over the crowns, and add sufficient fermenting material (consisting chiefly of leaves) to create a gentle warmth.

Seakale may now be brought forward in the same manner as just recommended for Rhubarb. The produce is generally superior when grown in this way to that forced indoors.

PUBLIC PARKS AND GARDENS.

By JAMES WHITE, Superintendent of the Parks and Open Spaces in the City of Glasgow.

Acquisition of sites.—Among the many problems which urban authorities are called upon to solve, the selection of a suitable site for a park or playground, which will best suit the requirements of the community, is frequently one of some difficulty. This difficulty sometimes presents itself in small towns as well as those of larger size, but in these cases the conditions are not so bad. In the busy centres of commercial and industrial cities the land famine has become very acute, and, in consequence of the high prices demanded one is tempted to say extortionate prices the progress of the establishment of open spaces and playgrounds, apart from the larger parks, is seriously hampered. This is a point on which one is at times constrained to speak somewhat strongly. We daily see the necessity for more open spaces in closely-built towns for the well-being of those who cannot afford to live in healthier localities. Recognising the shortcomings of the past, why, we ask, should the perpetuation of the evil be permitted in the present, to the detriment of the health of both present and future generations? We see agricultural land, by the accident of circumstance, through its proximity to an expanding city, rising an hundredfold in price; large blocks of tenements are built upon it, accommodating, it may be, a dozen families in each, but not a square yard is set aside by the owner for the purpose of the recreation of the hundreds of toiling beings who of necessity will have to live in these modern abominations of four or five-storied tenements. While disliking grandmotherly legislation, one is forced to ask the question why it should not be made compulsory on the part of every landlord, whose property is so greatly enhanced in value by the outgrowth of a city, to set aside a portion of the area, say one acre in ten, as an open space and playground for the benefit of the children of the community whose existence has been the cause of the increase of his wealth? A few landlords, to their credit, do recognise their responsibilities in this matter; but unfortunately the very paucity of the number who do so only emphasises the necessity for some stronger powers than exist for compelling others to do the same. This question should not have any place in party politics. It is one which ought to be dealt with on the plane of common humanity, and the man, no matter of which party, who has the courage and strength to formulate and carry into law such a necessary piece of legislation will deserve well of his country.

Looking ahead.—In so stating my views on a subject which is painfully acute in many of the larger and older towns in our country, I strongly advocate a policy of looking ahead. This policy, which is so important in regard to the case of small playgrounds, is equally applicable to that of the larger areas which fall more properly under the designation of public parks. Some readers may ask, what has a park superintendent to do with these matters? The reply is, any person responsible for the management of a department under a corporation or other local authority should study how his department can best serve the interests of the community whose servant he is. Questions dealing with the general policy of a corporation will, of necessity, from time to time arise, which may directly or indirectly affect his particular department, and the man who keeps himself acquainted with the various phases of municipal work will best be able to deal with points which the council or committee expect that he, from his technical knowledge, should be in a position to express an opinion upon, when any scheme is under their consideration.

THE APIARY.

By CHLORIS.

Care of the hives.—The time is fast approaching when the bees may be expected to take a much-needed cleansing flight. Some beekeepers will be eager to overhaul the hives, and all will be bustle and commotion. Those who are wise will be in no hurry to examine the brood chamber, but will be content to see if the roofs have been leaking, and, if so, they will remedy the defect, at the same time removing all wet quilts and substituting dry ones.

The use of strong-smelling chemicals, &c.—I am not about to discuss the use or abuse of the various chemicals which are written about and advertised as a certain cure for the various ills that befall bees, but it is my intention to relate a fact which I gleaned during a holiday spent among those who purchase the honey which we produce. I was examining some sample of honey, upon which a chemist, with a large honey business, wished me to express an expert opinion. He then related how he had nearly ruined his connection by purchasing from a new source when his regular source failed through the bad season. It seems the honey looked quite as good as any he had ever bought. He sold it in the usual way, and one of the first to purchase was a very good customer. The next day the lady returned, saying she was certain the chemist had had some very strong-smelling chemicals near it, as it had that taste and smell. He apologised, asking her to return it and he would replace it, thinking himself that some untoward accident had happened. Before the customer just named had time to return the section, a second customer called and made the same complaint, then he thought there was something wrong with the honey. So there was; every section smelled strongly of naphthalene, and the only use he could put it to was to make it up mechanically. If any beekeeper use anything strong-smelling as a preventative of disease, they will be well advised not to have it in the hives during the time the bees are busy storing.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens and plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, JANUARY 28—
Roy. Hort. Soc. Coms. meet.
Nat. Rose Soc. Com. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—39

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, January* 22 (6 P.M.): Max. 42°, Min. 33
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, January* 23 (10 A.M.): Bar. 30·4; Temp 41°, *Weather*—Foggy.
PROVINCES.—*Wednesday, January* 22 (6 P.M.): Max. 40° Guildford, Min. 32, Newcastle-on-Tyne.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY
Sale of Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY AND THURSDAY—
Perennials, Gladiolus, and other Bulbs, Azaleas, &c., at 12; 1,000 Roses at 1.30; by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

TUESDAY, WEDNESDAY, AND THURSDAY—
Sale of a fine assortment of Nursery Stock by order of Mr. John Fraser, at The Nurseries, South Woodford, by Protheroe & Morris, at 11.

WEDNESDAY—
Border Plants, Begonias, Gladiolus, &c., at 12; Roses and Fruit Trees, at 1.30; Palms, Azaleas, and Plants, at 5; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
Choice Imported and Established Orchids from various sources, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Experiments on Heredity.

About sixty years have passed since Darwin published the results of his remarkable investigations on the origin of new species, and proved that the facts of variation, coupled with the enormous death rate to which all organisms living in a state of nature are subject, provide the clue to the processes concerned in the production of new races.

Experience has amply confirmed the truth of the main principles of the Darwinian theory, for variation and mortality are still the cardinal points on which the doctrine of evolution hangs. But our attitude towards the problem itself has altered somewhat, and we are especially anxious at the present time to discover what is really involved in variation itself. For in the correct understanding of variation lies the kernel of the whole matter.

There are two main views as to the nature of variation itself, and the means whereby it is brought about. The one looks on the environment as the principal cause, whilst the other regards variation as the necessary outcome of an internal and intrinsic change in the constitution of the varying individual, and one that may be altogether independent of the influence of external conditions. A third party adopts an attitude of compromise, and considers the differences which arise to be due partly to inherent change, and partly to change in the environment.

Everyone who has endeavoured to produce new races of plants knows that hybridisation is a powerful engine with which to work. It is often said that in this manner we can "break the constitution" of a plant, and that the rest of the process is thenceforth a matter of selection. Others, again, assert that cultivation is the important condition, that instability of character is thereby engendered, and that in this way it becomes possible to start selection of new and desirable varieties.

These are rather vague statements when one endeavours to ascertain what they really mean, but each of them serves to disclose certain suggestive aspects of the large problem involved, and, moreover, they are just the two aspects which are now being experimentally studied, under the names of Mendelism and Mutation.

We are still very ignorant of the real nature of what are known as mutations—that is, alterations in the inherent structure of an organism which causes it to differ from its fellows, even when exposed to a similar environment. Variation of individuals from each other is universal, and mutations are sometimes spoken of, though quite improperly, as though they were merely of the nature of large variations. But this is far from being the case. As a matter of fact, the permanent, as opposed to the fluctuating, differences are sometimes, perhaps often, extremely minute, and are only to be detected by an expert. But they are distinguishable from the fluctuating variations in that they are stable, and they must, therefore, represent a real change in the constitution of the individual that possesses them.

We include under the term Mendelism a vast amount of new facts concerning the way in which parental characters are distributed amongst the offspring of each generation, and whatever may be the ultimate explanation of the exact machinery whereby the results are obtained in nature, nothing can lessen the immense importance of the knowledge thus recently acquired. For it enables us in a great measure to control, as well as to predict, the results of particular operations in a way that was formerly quite impossible. Naturally, many things are still obscure, and we are coming to recognise that the individual characters themselves are not always as simple as they may appear to be, nor are they always strictly comparable with each other. But the well-known formula $D + 2DR + R$ is found to apply to many of the instances in which, for want of full analysis, it formerly seemed to fail.

It is very important that the meaning of this formula should be properly appreciated, and perhaps no excuse is needed for recapitulating the facts upon which it rests.

It often happens in different races of the same species that a particular character, for example, stature, may be one of the features that distinguishes one race from the other. And when this is the case, the character in question may depend on some relatively simple structure present in the germ cell, which becomes evident as the individual which develops from it becomes mature. Thus Mendel found that certain races of dwarf and tall Peas respectively always bred true in regard to stature. But when the dwarfs and talls were hybridised, he did not get individuals which graded from dwarf to tall, but the whole offspring was tall. On allowing the flowers of this first generation (often distinguished as the F1 generation) to be self-pollinated, and sowing the seeds that resulted, he obtained in the second (the F2) generation, talls and dwarfs in the proportion of three of the former to one of the latter. Further experiments showed that the dwarf always bred true, and that some of the talls did the same, but that an average of half the whole offspring, consisting of individuals which were indistinguishable from pure talls, were really hybrid in character, inasmuch as they threw out dwarfs in each generation. Now, the fact that the hybrids of the F1 generation were all tall, whilst, when they were mated together, dwarfs appeared in the next one, shows that the dwarf character contributed by one parent was present, but was rendered latent in the offspring by the simultaneous presence of the other character, that of tallness. And a careful analysis of the results renders it almost certain that the germ cells formed in the pollen tube and in the embryo-sac of the ovule respectively, each contain only *one* of these two characters, until a mingling occurs at fertilisation.

The chances of a germ cell mating with another germ cell containing either the same or the opposite character are exactly equal, and if we confine our attention to the two opposing characters only, there will be four possible unions, namely, tall × tall, tall × dwarf, dwarf × tall, and dwarf × dwarf. But when the property of tallness is present, the dwarf character is latent, so when the hybrids are mated, there will be three talls to one dwarf. The three talls are not all alike. One in every three is purely tall, whilst the other two are still hybrid; and as the tall character is dominant (D) over the latent or recessive (R) character we see that the result may be expressed in general terms by the formula already alluded to.

This is a very simple case. Many other examples could be mentioned that are far more complex, but they would demand for their discussion far more space than we are able to give. We may, however, remark in passing that an increasing number of so-called reversions are susceptible to Mendelian interpretation, and thus are brought well within the domain of experimental treatment, and the results of these investigations are throwing considerable light on the nature of the mechanism of heredity.

An account is given in another column by Mr. A. W. Sutton of his remarkable and important experiments on the hybridisation of species of Brassica. The value of such experiments extends far beyond the immediate gain in the production of new forms of economic value, though this result has also been achieved. The manner in which the characters of the parents sometimes disappear in the F1 hybrid is, of course, what one would anticipate, but the apparent reversion to worthless, wild forms is suggestive in the highest degree, especially when it is found that in the F2 generation the cultivated characters may reappear, though in a modified form. It is evident that a further field is opened up for research along valuable lines that, as yet, have hardly been touched. We would especially refer to the behaviour of such characters as fleshiness, and their

distribution amongst the hybrids. The remarkable way in which this feature behaves is specially interesting when we reflect that it is one that is particularly liable to be affected by the environment. Everyone knows how differently fleshy plants develop according to whether they are grown in good, or in poor neglected soil. It is, therefore, of considerable importance to find that this character, which has sometimes been appealed to as proving the all-importance of the environment, should so clearly indicate its primary relation to the inner constitution of the organism as determined by the fusion of the parental germ cells. The facts seem to point to the conclusion that the exhibition of certain characters of this sort can only appear if the properties on which they depend are already present in the individual, but that on the other hand they may lie more or less dormant unless they are stimulated to expression by a suitable environment.

ROYAL HORTICULTURAL SOCIETY.—At the meeting of the Committees of this Society on Tuesday next, January 28, in the Vincent Square Hall, Westminster, a lecture on "Self-Coloured Photographs of Switzerland and the Swiss Flora" will be delivered by Mr. T. ERNEST WALTHAM, at 3 p.m., illustrated with lantern slides. Mr. A. W. SUTTON will read a paper on Brassica hybrids at the meeting of the Scientific Committee at 4 p.m. in the Lecture Room, and will illustrate his lecture by lantern slides.

R.H.S. GUILD.—With the view of keeping past and present students and employés in the gardens of the R.H.S. in touch with one another and with the work of the Society, it has been decided to form a R.H.S. Guild. A half-yearly magazine will be issued, comprising articles and letters contributed by members, notes on the work of the Society in the gardens at Wisley, exhibitions, &c., general notes of horticultural interest, and a list of members with their addresses. An annual dinner will probably be arranged for the first day of Holland Park Show. The fee for membership is provisionally fixed at 5s. a year. Old Chiswick and Wisleyites are asked to communicate with the hon. sec., Mr. R. J. WALLIS, R.H.S. Gardens, Ripley, Surrey.

THE DEVON AND EXETER HORTICULTURAL SOCIETY will hold its autumn show on Friday and Saturday, October 23 and 24, in the Victoria Hall, Exeter.

CHESTER PAXTON SOCIETY.—At a meeting to be held on February 1, a lecture on "The Common House-Fly" will be delivered by Mr. R. NEWSTEAD, A.L.S., F.E.S., &c., illustrated by lantern slides and specimens. On February 15 the subject of the lecture will be "The Flora of India and Ceylon," by Mr. JOSEPH THOMPSON, illustrated by a series of lantern slides, and on February 29, "Herbaceous and Alpine Plants," by Mr. W. S. SHARP.

THE THIRD QUINQUENNIAL INTERNATIONAL CONGRESS OF BOTANISTS.—In 1905, at the wish of the Vienna Congress of Botanists, the Belgian Government agreed to the holding of the Congress of 1910 at Brussels, and M. TH. DURAND and Prof. ERRERA were appointed chairmen of the executive committee. Less than two months afterwards Prof. ERRERA died suddenly, and the Count OSWALD DE KERCHOVE DE DENTERGHEM, who had accepted the position vacated by the death of Prof. ERRERA, died also in March, 1906. The question of the transfer of the State Botanic Garden of Brussels being put forward, the Government asked the International Association of Botanists to hold the third Congress (1910) elsewhere and to hold the fourth Congress (1915) at Brussels instead. Action in this sense was agreed upon, but in July last the idea of holding the third Congress at Brussels was again taken up by M. HELLEPUTTE, Minister of the Board of Agriculture *ad int.*, and the Baron DESCAMPS, Minister of the Science and Art Department. The Baron DE MOREAU D'ANDOYE, formerly Minister of Agriculture, kindly accepted the position rendered vacant by the death of the late Count DE KERCHOVE. A preliminary meeting was held on January 16 in the State Botanic Gardens at Brussels, M. DE MOREAU presiding, and there were present MM. TH. DURAND, president of the committee of organisation, DE WILDEMAN, general secretary, HEGH, secretary, VAN DER VAEREN, treasurer, and VAN AERDSCHOT, assistant-treasurer, MM. PROOST and VAN OVERBERG (general directors), together with the best known of the Belgian botanists. The provisory lists of honorary members and the members of the Executive Committee, and Sub-committees, were elaborated. The programme and rules of the Congress were also discussed. A second meeting will be held on Wednesday, January 29.

EMIGRATION TO NEW ZEALAND. The High Commissioner for New Zealand desires to direct special attention to the fact that persons suffering from consumption and unable to provide for their maintenance inside a sanatorium cannot be allowed to land in New Zealand. Indigent sufferers are required to return by the next boat leaving after their arrival, and it is therefore specially important that consumptive patients of that class should be warned not to go to New Zealand.

"WILLING'S PRESS GUIDE."—The receipt of the issue of this work for 1908, being the thirty-fifth year of its existence, reminds us of the useful information it contains upon the publications of the United Kingdom. In addition to an exhaustive list, the publications are classified into counties, types, and according to their frequency of issue, and information on many other matters is given. It is published at the price of one shilling.

FRUIT IN THE BERLIN IRRIGATION MEADOWS.—The annual report of the deputation for the Rieselfeldern, or water meadows, contains some interesting matter. The peculiarity of a water meadow is that it requires a great number of roads or tracks. With the view of making these broad roads (6 yards) of use financially, they are planted with fruit trees, and most of these are now ten years old, and are coming into bearing. Until recently the trees have been let to yearly tenants, but the owners will now cultivate the trees and harvest the crop at their own cost. The result throughout has been most satisfactory, for whereas in previous years the income in the form of rent in no year has exceeded 8,000 mk., in two years the fruit sales brought in 84,000 mk., and the last year 100,000 mk. The present year the crop of Apples and Pears amounted to several thousand centner, and was disposed of by direct sales.

DR. HERMANN GRAF ZU SOLMS-LAUBACH.—This well-known Professor of Botany at Strassburg, and Director of the Botanical Garden at that city, relinquishes his post at the conclusion of the present semester. He was at one time a frequent correspondent of this journal, and his various contributions on botanical matters have been noticed in its pages. He will be succeeded by Prof. Dr. Friedr. Oltmanns, Director of the Botanical Gardens at Freiburg.

BANANAS VERSUS PLUMS IN ENGLAND.—The abundant crops of Plums which have been experienced in England during the past season have, it is stated, been the cause of a discussion carried on in many newspapers as to the relative food value of this native fruit compared with the imported Banana. This discussion, states the *Agricultural News* (West Indies), has chiefly centred round the Victoria Plum and the Canary Banana. A well-known West of England paper has taken a prominent part in debating the question, and has advanced in its columns a mass of figures and arguments in support of the assertion that English Plums are 50 per cent. cheaper, on the basis of their nutritive properties, than Canary Bananas, and also far better adapted for English consumption, from a health point of view, than the imported fruit. Plum growers, it is urged, should adopt the methods which have been utilised with so much advantage by Banana producers and dealers, and, by the judicious dissemination of literature, impress upon consumers the nutritive value of the home-grown fruit. By this means, it is hoped, English Plums will largely displace Bananas on the home market. Without for a moment wishing to disparage the qualities of the delicious English Plums, it is obvious that there is no comparison between this fruit and the Banana as regards food value. The latter contains nearly ten times the amount of albuminous constituents possessed by the Plum; it also contains more than ten times the amount of sugar, and rather more mineral matter. The nourishing properties of the Banana have been long recognised in England, and the fruit has come to stay. Further, the uncertain nature of the English Plum crop, and the fact that this fruit is available in its fresh condition for only a short period of the year, give it no chance of displacing the Banana, which can be obtained in fresh supply from January to December.

THE PRICKLY PEAR IN AMERICA.—Although the spread of this plant has aroused considerable apprehension in South Africa and Australia, it forms one of the important economic food-plants in Mexico, where it is largely grown for the sake of its edible fruits. A recent number of the *Bulletin of Plant Industry* is devoted to a lengthy report on this Cactus, which goes by the name of Tuna in Mexico, and it seems to suggest that the plant may possibly rise in general esteem. One disadvantage associated with the fruits lies in their prickly character, and another in the disagreeable sensation, at least to most non-Mexican people, produced by the seeds. It is well known that BURBANK has cultivated forms which, so far as the vegetative organs are concerned, are spineless, and afford valuable food for cattle in hot, dry districts, but even these possess more or less spiny fruits. The same capacity for variation is also associated with the fruits, of which there are many distinct sorts recognised by the Mexicans. Some of these, like the Tuna naranjada, contain much less seed than other sorts, and the general impression derived from reading the report is that the Opuntia is decidedly worth taking up with the view of breeding new races of economic value. If these efforts should be seriously undertaken, and should meet with success, it may be possible to replace the unpopular sorts that at present are rampant in South Africa and Australia by desirable varieties. The principal disadvantage of the fruits as now grown seems to lie in their tendency to produce constipation; but the fact that, in this respect again, the various sorts differ much amongst themselves, is a hopeful sign for the future.

Publications Received. *The Art of Landscape Gardening*, by Humphry Repton. Edited by John Nolen, A.M. Published by Archibald Constable & Co., Ltd. Price, 12s. 6d.—*The Book of Garden Pests and Plant Diseases*, by R. Hooper Pearson. Published by John Lane. Price, 2s. 6d.—*A B C and A Y Z of Bee Culture*, new edition, by A. I. Root and E. R. Collingridge. Price, 1s. and 1s. 6d.

NOTES ON BRASSICA CROSSES.*

THE practical culture of plants for seed naturally affords many opportunities of studying the processes of nature, which the ordinary pursuits of agriculture and horticulture do not, and it was probably on this account that I was invited some years ago, with my friend, Mr. Harry Veitch, to represent the Royal Horticultural Society on a joint committee, with Mr. Bateson representing the Evolution Committee

FIG. 26.—BRUSSELS SPROUT WITH CABBAGE HEAD.

of the Royal Society, in order to note and record any natural phenomena which might illustrate the theory of evolution.

I was first led to commence this special series of experiments in Brassica crosses by the statement of a writer in one of the agricultural journals, to the effect that various plants of the Brassica tribe, including some of those most important to agriculturists, would not cross naturally, or, in other words, seed-crops of these plants might safely be grown in close proximity without any fear of inoculation. As a practical seed-grower, this statement could not fail to arrest my attention, because experience had always shown that, while certain Brassicas could safely be seeded close to one

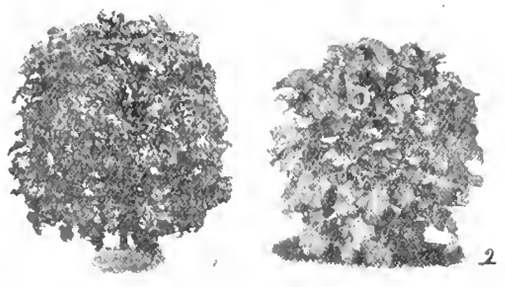

FIG. 27.—(1) A HARDY CURLED FORM OF 1,000-HEADED KALE. (2) THE PARENT FORM OF 1,000-HEADED KALE, FOR COMPARISON.

another, other could not be so grown for seed without injury. Possibly the fact that *some* members of the Brassica family will not intercross may have led the writer to conclude that this was true of all. However this may be, I decided to put the question to a practical test, and in the year 1900 set out several plantations for seed. The plants obtained by sowing the seed were duly examined, and afterwards reported upon in various agricultural and horticultural papers in the spring of 1902.

The results were very much in accordance with my expectations, and, in some cases, confirmed the unfortunate result which occasionally follows when a farmer inadvertently allows two crops to seed near one another.

I did not anticipate that new types of much practical importance to agriculturists or to gardeners would result from these experiments, because we have already an almost endless variety of economic plants of the Brassica family, most, if not all, of which have reached their present state of perfection through a long period of careful selection from a single type, each seeded year by year in perfect isolation. At the same time, there were possibilities of new combinations, and it is interesting to note that some have been well fixed and are likely to become very popular vegetables or plants of economic value.

The following were seeded side by side and allowed to intercross naturally:—

Green Kale, Variegated Kale, Thousand-headed Kale, Savoy, Brussels Sprouts, Drumhead Cabbage, Garden Cabbage, Red Cabbage, and Couve Tronchuda.

The hybrid plants obtained from seeding all these types together were most nondescript in character. The majority were discarded as being of no practical value, but the following are likely to be useful in the future, and some are being perpetuated —

A Brussels Sprout with Cabbage head (fig. 26).

A plant like Thousand-headed Kale, but with curled leaves (fig. 27).

A plant like Thousand-headed Kale, but with large, tender leaf stalks similar to those of Couve Tronchuda.

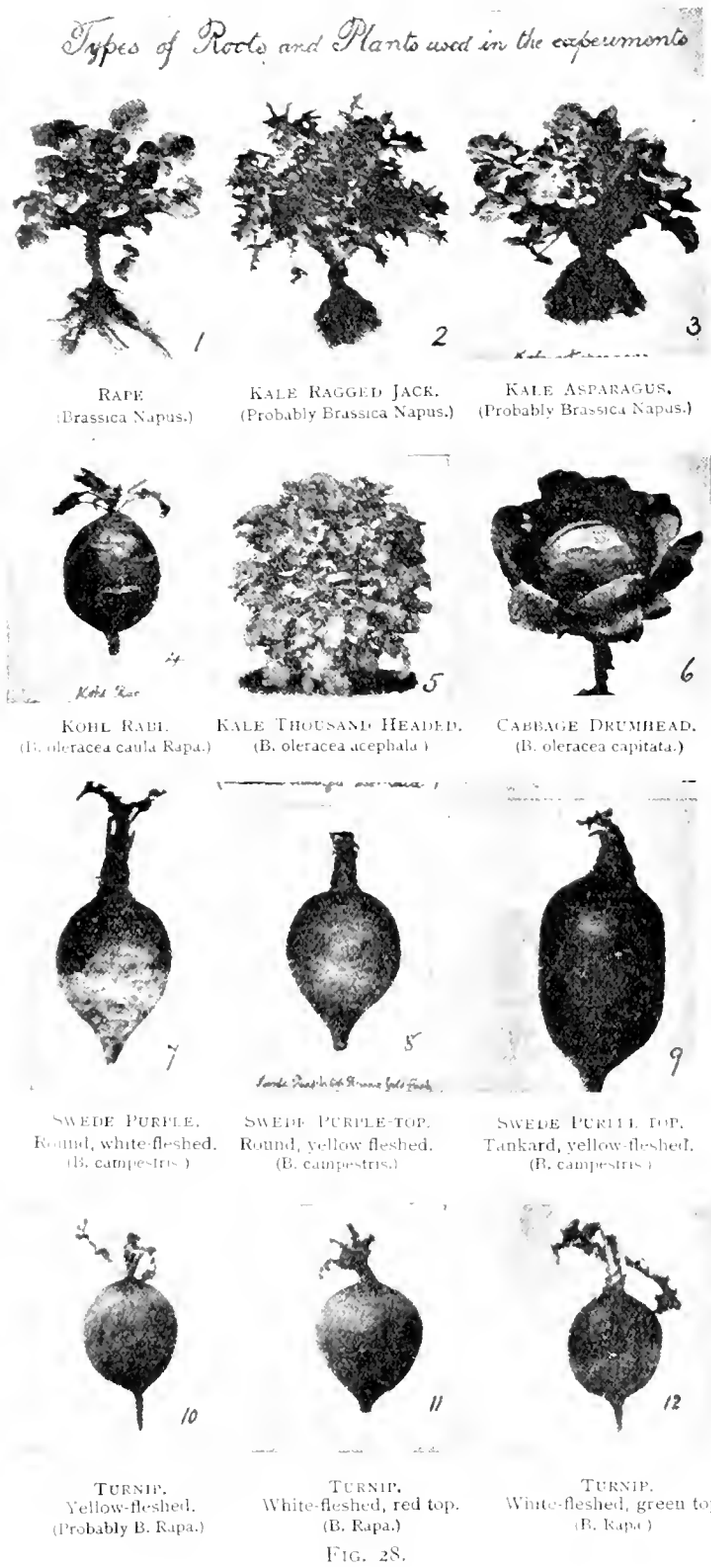

FIG. 28.

* Extracts from a paper read before the Linnean Society, January 16, 1908.

A hearting or heading form of Couve Tronchuda.

Having seen the results from seeding various forms of the Brassica oleracea side by side, I decided to continue the experiment by including other types of Brassicas, such as Rape, Swede, and Turnip (B. Napus, B. campestris, and B. Rapa respectively). These, with Kales, Cabbages, and Kohl Rabi, were seeded side by side in 1902, and, as in the case of the original experiments in 1900, I obtained a most extraordinary collection of hybrids, but there was no trace of any of the Cabbage class being affected by Rape, Swede, or Turnip, nor were any useful novelties obtained. I showed the results of these crosses to my friend, Professor Percival, Director of the Agricultural Dept., Reading College, and we determined to see whether crosses could not be obtained between Brassica oleracea and some types of Brassica Napus, Brassica campestris, and Brassica Rapa, by artificially fertilising the flowers *under such controlled conditions as would make it almost impossible that any chance fertilisation of the flowers should vitiate the experiment.*

There are, as many persons are aware, two distinct types of Swede, besides scores of more or less different varieties. These two distinct types are the yellow-fleshed Swede and the white-fleshed Swede. There are also two distinct types of Turnips, the yellow-fleshed Turnip and the white-fleshed Turnip. There has been a vulgar tradition that the yellow-fleshed Turnip is a hybrid form between the yellow-fleshed Swede and the white-fleshed Turnip, and so generally accepted has the tradition been in some quarters that yellow-fleshed Turnips have been commonly known as "hybrid" Turnips. But opposed to this tradition is the fact that there is no authentic record of any yellow-fleshed Turnip of commerce having been produced in this way, nor has any chance seeding of a yellow-fleshed Swede side by side with a white-fleshed Turnip given rise to a hybrid form at all corresponding to the yellow Turnip.

If the yellow-fleshed Turnip does not owe its origin to a cross between a yellow-fleshed Swede and a white-fleshed Turnip, from whence have we obtained the yellow-fleshed Turnip? Again, are Swedes, whether yellow-fleshed or white-fleshed, so closely related to Turnips, whether yellow-fleshed or white-fleshed, that we may conclude they have a common origin, or do they differ so specifically that we must admit a separate origin? It is, of course, well known that,

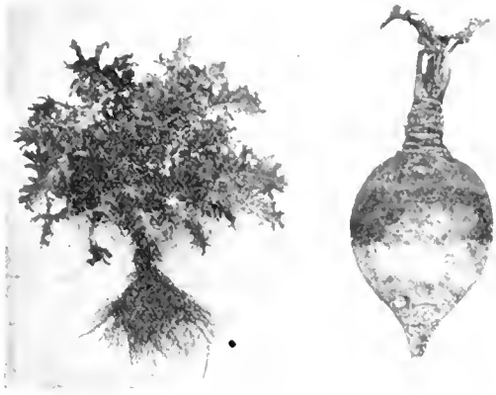

FIG. 29.—PARENT PLANTS RAGGED JACK KALE × WHITE SWEDE.

though in England Swedes are known as Swedes, and Turnips as Turnips, yet in Scotland and in Ireland farmers generally use the word "Turnip" to describe both Swedes proper and Turnips of all kinds. We, therefore, decided to take the leading types of Brassicas most commonly used on the farm or in the garden, and individually cross them with each other, taking every due precaution as to the emasculation of the flowers to be pollinated.

I may at the outset state that these first crossings, made in 1904, gave us, when any combination occurred, just the results in F1, which experience had led me to expect, and, conversely, when no combination occurred, this was also in strict agreement with previous experience. But when Professor Percival, Mr. Bateson, myself, and others met to examine the plants of F1 in the autumn of 1905, we saw at once that, by "selfing" these plants, we should have an unique opportunity of testing the Mendelian theories, which led Mr. Bateson to feel confident that in F2 we should find the "progeny" splitting up and giving us back again the parental types in definite proportions.

The plants of F1 were not hand-pollinated, but well isolated and covered in with tiffany or muslin. The types taken for the experiment were: — Rape, Ragged Jack Kale, Asparagus Kale, Kohl Rabi, Thousand-headed Kale, Drumhead Cabbage, white-fleshed Swede, yellow-fleshed Swede, yellow-fleshed Turnip, and white-fleshed Turnip (fig. 28). The number of crosses attempted was about 86, although if all the possible combinations had been tried the total would have been 210. Many of these attempted crosses, as we naturally anticipated, gave no seed at all, perhaps indicating that cross-fertilisation was impossible. Another group gave seeds which were poor or immature and would not germinate. Still another group gave seeds which grew into plants and roots, and these, when planted out for seed, were either killed by the weather or were sterile and produced no seed. The general character of these plants resulting from the crosses was, of course, that of mongrel or bastard types, and in only a very few cases could the experiments be continued to the second generation, probably owing to sterility. The point, however, which I wish to specially emphasise is that, where the experiment was continued to the second generation, we found in almost every case the hybrid form split up, and gave us in F2 plants, a certain number of which resembled the parental types, whilst others were intermediate types.

FIG. 30.—HYBRID (F1) RESULTING FROM CROSSING RAGGED JACK KALE WITH WHITE SWEDE.

Taking first the cases in which no seeds were produced from the original crosses. Rape did not cross with Kohl Rabi, Thousand-headed Kale, or Drumhead Cabbage.

Ragged Jack and Asparagus Kale did not cross with Kohl Rabi, Thousand-headed Kale, Drumhead Cabbage, or with white Turnip.

Thousand-headed Kale and Drumhead Cabbage crossed with none but Kohl Rabi.

Neither white-fleshed Swede, yellow-fleshed Swede, yellow Turnip, nor white Turnip would cross with the Cabbage class.

The next group consisted of plants of F1, which, when put out for seed in 1906, proved sterile, or were destroyed by the weather. They were: — Asparagus Kale on yellow-fleshed Swede; white Turnip on Asparagus Kale; Ragged Jack Kale on yellow-fleshed Swede; yellow-fleshed Swede on Ragged Jack Kale; Rape on yellow-fleshed Swede; Rape on white-fleshed Swede; white-fleshed Turnip on Rape; yellow Turnip on Rape; yellow Turnip on Ragged Jack Kale; white Turnip on white Swede; Rape on yellow Turnip; yellow Turnip on yellow Swede; yellow Turnip on Ragged Jack Kale; yellow Turnip on white Swede; yellow Turnip on white Turnip; white Turnip on white Swede; white Turnip on yellow Turnip; white Turnip on yellow Swede.

The last section is that resulting from crosses which, having produced hybrid forms in F1, have also produced plants or roots in F2, splitting up, as I have already indicated, into forms resembling the types first cross-fertilised, and other intermediate forms. They are as follow:

Kohl Rabi on Thousand-headed Kale: 207 plants grown, 154 bulbing, 53 non-bulbing; proportion of bulbing plants about 3 to 1.

Thousand-headed Kale on Kohl Rabi: 201 plants grown, 135 bulbing, 66 non-bulbing; proportion of bulbing plants about 2 to 1.

Kohl Rabi on Drumhead Cabbage: 215 plants grown, 45 bulbing, 170 non-bulbing; proportion of bulbing plants about 1 to 4.

Drumhead Cabbage on Kohl Rabi: 195 plants grown, 46 bulbing, 149 non-bulbing; proportion of bulbing plants about 4 to 13.

Thousand-headed Kale on Drumhead Cabbage: 204 plants grown, 176 much like a dwarfer type of Thousand-head, 26 Cabbage-like, and 2 resembling rather the Brussels Sprouts.

Ragged Jack Kale on white Swede (figs. 29, 30, 31): 198 plants grown, 160 bulbing, 38 non-bulbing; proportion of bulbing plants 4 to 1. Foliage, Swede-like 142, Ragged Jack-like 38, intermediate 18.

White Swede on Ragged Jack Kale: 191 plants grown, 136 bulbing, 58 non-bulbing; proportion of bulbing plants about 5 to 2. Foliage, Swede-like 156, Ragged Jack-like 33, intermediate 5.

Purple-top yellow round Swede on Asparagus Kale: 208 plants grown, 178 bulbing, 30 non-bulbing; proportion of bulbing plants about 6 to 1. Foliage, Swede-like 126, Asparagus Kale-like 82.

GENERAL CONCLUSIONS.

From the foregoing it will be seen that Brassica oleracea (Cabbage type) will not cross outside its own class; but that Brassica Napus, Brassica campestris, and Brassica Rapa (Rapes, Swedes, and Turnip) crossed with each other and produced hybrids, although many of these hybrid plants failed to produce seed, and could not therefore be perpetuated.

FIG. 31.—OFFSPRING OBTAINED FROM SELF-FERTILISING THE HYBRID SHOWN IN FIG. 30.

There is no doubt that the origin of these latter types is very obscure, and much confusion exists in their classification.

It seems also a fair deduction to make that, as it was impossible to perpetuate the hybrid forms between white and yellow Swede, white and yellow Turnips, white Turnip and Swede, yellow Turnip and Swede, or vice versâ (for the reasons above mentioned), it is probable they do not owe their existence to a cross with a wild form. *Arthur W. Sutton.*

RAILWAY RATES.

MOVEMENT BY THE GROWERS.

THE public in general, and nurserymen and market-gardeners in particular, owe a debt of gratitude to the *Daily Telegraph* for having enabled growers to bring to public notice the hardships which they suffer under the present railway regulations. Such a policy cannot but be productive of good to both parties, inasmuch as railways rely upon the trader for a large proportion of their profit, and a reasonable complaint left unremedied is apt to militate against that expansion of trade which it should clearly be to the interest of the railways to promote. It is, of course, equally true that without adequate provision for transit of goods commerce must suffer proportionately.

The correspondence in the *Daily Telegraph* opened on the 14th inst. with an interview with Mr. George Monro, of Covent Garden, on the subject of railway hardships as they affect the grower. This was soon followed by letters from such well-known growers as Mr. Cuthbertson (Dobbie and Co.), of Mark's Tey, Mr. Charles A. Pearson, of Nottingham (writing officially as honorary secretary of the Horticultural Trades' Association of Great Britain and Ireland), Mr. Jackman, of Woking, Mr. Wm. G. Lobjoit, of Hounslow (writing officially as vice-president of the Market-Gardeners', Nurserymen and Farmers' Association), in addition to Messrs. Edward H. Lewis and Son, of Covent Garden, and "R. E. M." Readers may be interested to hear that the latter initials modestly hide the identity of Mr. R. E. Moore, the able counsel who has recently revised the short Act of Parliament drafted on behalf of the Joint Railway and Parliamentary Committee as a sample (for Mr. Lloyd George's perusal) of the practical remedies required to mitigate the growers' grievances. By the time these lines appear in print probably other letters from the trade will have been published, and it is certainly encouraging to those who have for so long laboured to obtain ventilation of this subject in the daily Press to find that their efforts have at last met with success. For the reasons which are explained later, growers now have a chance which may not again occur during the present generation, and it is to be hoped that, in their own interests, they will seize without delay the opportunity thus offered. As Mr. Charles A. Pearson points out in his letter above referred to, the only hope of securing amendment is to convince "the man in the street" of the reality of the grievances, so that those in authority may be induced to take a right view of the matter. But to achieve this object it is necessary to bring forward concrete *instances* of the hardships which exist. Every grower meets with such instances in the course of his business, and if a short letter from each one were published in the *Daily Telegraph*, relating his special troubles in respect of high railway rates, refusal of reasonable compensation for damage, careless handling of goods, unreasonable delay, want of proper facilities, or unfair treatment generally, an overwhelming body of evidence would be forthcoming to support the case of the growers. Knowledge of railway law is quite unnecessary for this purpose. It is *facts* which are needed. The technical points of the matter, and the remedies advocated, are being dealt with by the members of the Joint Railway and Parliamentary Committee, which represents the numerous associations of traders who deal in perishable goods. The members of this committee, under the presidency of Mr. George Monro, have made a special study of the subject, but, to a large extent, they must obviously rely on the individual trader to supply them with the requisite amount of information.

Those who desire to have further assistance or information on the subject should communicate at once with Mr. H. W. Goodall (at his offices in the Tavistock Hotel, Covent Garden, London), the secretary to the committee.

It is evident that there is not a moment to be lost. Already the railways are combining in an attempt to force up rates, and are commencing their campaign. Let those who fancy this danger to be imaginary or in any way exaggerated read and digest the following announcement which appeared in the *Daily Telegraph* on Saturday last.

INCREASED RAILWAY RATES.

PROPOSED JOINT CONFERENCE.

"A special meeting of the members of the Railway Companies' Association was held in London yesterday, when consideration was given to a proposal to promote a conference with a view to raising and adjusting the existing railway rates.

"At the time of the railway settlement the question of the restrictions under which the companies at present suffered in this direction was brought forward, and the President of the Board of Trade then promised fully to investigate the subject.

"A conference, to be attended by representatives of the railway companies, merchants, traders, and other interested bodies, is favoured, as against a Royal Commission, which it was originally suggested should be appointed to inquire into the whole question and report.

"Mr. Lloyd George is giving his support to the holding of a conference, as a result of which some definite and joint action will, it is expected, be decided upon."

The matter is thus put very gently and diplomatically for the Railway Companies' Association, but the paragraph openly confesses that it is desired to force up railway rates. And what more does it imply? At the worst, it may tempt some to give credence to the rumour that the railway companies are endeavouring to induce the Government to enter into a bargain whereby, in consideration of the railway companies raising the wages of their servants (a comparatively small section of the labouring classes in comparison with the working population of the country), instead of providing the necessary funds by increased internal economy and a sounder commercial policy, the railways are to be allowed to force up rates. If the prices of fruit, vegetables, and other foods are to be thus increased, it is well to bear in mind that, although part of the cost may fall on the consumer, the whole of the increase certainly will not do so having regard to the competing prices of foreign growers who import their produce at specially-reduced railway charges far below those paid by home growers. Furthermore, in so far as a portion of the increased rates falls on the consumer, undoubtedly "our food will cost us more," and, without any corresponding benefit, the pinch will thus be felt by the gardener and working classes in common with the rest of the public. This is a point upon which both Free Traders and Tariff Reformers will, presumably, be in agreement. It may be suggested that the above argument does not assist the nurseryman and seedsman. But surely the plea in their case is even stronger, because the young fruit trees and seeds supplied by them are to the market-gardener what "raw material" is to the manufacturer.

At the best, the newspaper extract quoted above shows that a conference between the representatives of the various railway companies and the traders is to be held under the auspices of the Board of Trade, for the purpose of discussing not only the existing obsolete classification of goods (which bears so hardly upon the grower), but even the question as to whether railway rates should be raised, lowered, or remain unaltered, the various trades being considered piecemeal.

Each trade will doubtless protest that it must be spared, and that if increased income for the railways is essential, it is some other trade which must suffer. And which trades are most likely to gain benefit from this conference, or, at all events, to emerge least unharmed from the ordeal? Obviously those who take care to make known their special trade grievances and press for amelioration. Who could complain if the interests of growers should be overlooked or misunderstood by the President of the Board of Trade if the growers themselves remain silent and inert during the struggle? This was the attitude of the growers (principally owing to want of proper organisation) in the year 1888, when in effect the present classes for goods were fixed, and the trade has suffered in consequence ever since.

It is rumoured (though one is not yet in a position to make any authoritative announcement on the subject) that the proposed conference will consist of only a few members (many trades being left out) in addition to three independent persons nominated by the Board of Trade. If such is to be the case, it is earnestly to be hoped that at least one of the trade representatives will be specially qualified to speak on behalf of the fruit, flower, and vegetable trades, they being amongst the chief sufferers. Failing this, it is of vital importance that full information should be supplied by other means both to the trade representatives and to Mr. Lloyd George himself. Vague statements will be useless; practical instances, with dates and figures, will be absolutely necessary.

Nurserymen and market-gardeners must now be prepared to work out their own salvation, and every individual grower can lend valuable aid. First, by writing to-day to Mr. Goodall, at the Tavistock Hotel, giving instances of trade grievances under present railway regulations. Secondly, by vigorously strengthening the hands of those trade organisations which have taken the matter up; and, thirdly, by at once directing the attention of Members of Parliament to the subject. *H. Morgan Veitch.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE YELLOW FRUITED MIRABELLE PLUM (see pp. 28 and 44).—There is a good-sized tree of this Plum growing in the orchard here, and we get good crops of fruit from it in most seasons. In the past season it bore the heaviest crop I have seen in the past nine years. It is planted near the red-fruited variety, and together they have a very pretty effect when in fruit. There are two other trees of the red variety; one is a very large tree, and had it not been well supported by a dozen large struts, every branch would have been broken down by the weight of fruit. Both varieties make a good preserve, and are useful in the kitchen in many ways. Our trees are well sheltered by rows of Walnut trees; being so early to flower these Plums are liable to be cut by spring frosts and the cold winds that we get in this district. We are so near the chalk that the soil is much drier and warmer than in many localities. If trees were planted in less favoured situations they would probably fail to crop. *S. Burgess, Northdown Gardens, Margate, Kent.*

——— This variety has been grown here since 1886, when the late Duke of Rutland brought some trees home from Cronberg, in Germany: they have grown well, and are now 16 feet high, and the same in diameter. I would not advise anyone to plant this Plum extensively in the Midland or Northern districts; it bears freely, but requires a warm season to ripen its fruit. Last year many of them failed to reach their full size here. In warm seasons, when they ripen better, the fruits are much appreciated for the making of tarts and preserves, owing to their excellent flavour, when cooked, which is very similar to that of Apricots. I consider the variety worthy of a place against a wall for this reason, although the fruits are very small and have scarcely any flavour before they are cooked. The late Duke told me the variety was very plentiful in some parts of Germany. *W. H. Divers, Belvoir Castle Gardens, Grantham.*

PEAS.—Probably too many varieties of Peas are cultivated in gardens. Anyone requiring seed Peas, and especially the amateur, must be rather bewildered when perusing the long list presented to his gaze in most of the seed catalogues now published. The chief point is to grow varieties suited to the soil and position; for instance, an exposed garden without protective walls in a bleak locality is a bad situation for tall-growing varieties. As Mr. Bartlett (page 410, Vol. XLII.) pointed out, Pears are in many instances sown far too thickly, and a hint should be taken from his remarks for application to the Sweet Peas. They require deep cultivation to be satisfactory during a dry, hot summer, with something in the shape of good rotten manure for the roots to grow in low down, out of the immediate reach of the scorching rays of the sun. During the past summer I was much impressed with the Peas grown by Mr. Edmunds at Whitchurch, Hants. The varieties were William Hurst, Gradus, and

Duchess of Albany. The two latter varieties were cultivated in rows some distance apart, with a breadth of Potatos between the rows. The variety William Hurst produced a grand crop, and as a dwarf variety requiring no stakes it is scarcely excelled. Another dwarf growing variety cultivated by Mr. Edmunds had larger pods, but was neither so full in the pod nor as early as William Hurst. It is very beneficial to Peas to sow them in a shallow trench, that when artificial watering has to be resorted to they may receive a good soaking and reap the benefit of its application, after which they should receive a mulching of short manure to hinder evaporation. Years ago we raised our early Peas in small pots for planting out First Crop or Ringleader—but with that system I do not now agree. We sow seeds outdoors in a sheltered position, and protect and encourage them to grow when they appear through the ground and subsequently. *George Potts, Woodcoteside, Epsom.*

PREVENTION OF CORRUPTION ACT, 1906.—It is proverbial that onlookers see most of the game, and as I am in the position of neither giving nor receiving secret commission, I should like to contribute a few remarks, since, with your usual impartiality, you are publishing letters on both sides of this question. First, I wish to say I am convinced that the general public recognises the gardener to be what he undoubtedly is, viz., a hardworking, honest, simple fellow—attributes which, be the reason what it may, are shared by most of those who pass their lives in daily companionship with Mother Earth. If the average gardener were told that he would sell his honesty for a small commission on orders he would be sincerely indignant at such an imputation. At the same time, one is bound to recognise that the giving of commission *secretly* is a practice which may *unconsciously* influence the judgment of the receiver more than he himself suspects, and, in any case, may, by the mere temptation of the thing, tend to increase the number of black sheep which are to be found in every fold. Secondly, it is correct that this new Act aims impartially at secret commissions in every trade. It affects equally the coachman, the gardener, the chauffeur, and the business manager; indeed, all who are entrusted with the duty of buying goods for their employers, including such a person, for instance, as the managing director of one very large trading concern (of whom I heard recently) who draws a secret commission of several hundreds a year from certain coal companies. Thirdly, it is useless, from the purely practical point of view, to discuss whether the intentions of the gardener who accepts secret commissions are honest or not. It simply does not matter. The really vital question is what view the judges will take in case of prosecution, and as Sir E. Fry was for many years a judge, his letter at least shows what amount of mercy the judges will extend towards any unfortunate offender who comes before them. Lastly, I do hope that the gardener, for his own sake, will not put his head into a noose from which there can be no withdrawal. I suppose that those nurserymen or seedsmen who decide to run the risk will not pay the secret commission themselves, but will entrust that dangerous duty to some unfortunate representative, and when things begin to leak out, as they always do in this world, what will happen? Let the gardener study human nature (or at least remember what one reads almost every week in the daily papers) and draw his own conclusions. The representative's first thought will naturally be to save himself, and the usual way to do that is to "turn King's evidence" and give information against the other guilty person in return for a free pardon for one's-self. The gardener, in his simplicity and loyalty will not think of doing anything of this sort, and so he will inevitably be made the scapegoat, and be left to bear the odium of prosecution, while the tradesman's representative goes free. The trap is obvious. *Onlooker.*

——— Having had over 50 years' experience as a gardener, I read with much interest Sir E. Fry's letter on p. 439, Vol. xlii., and those that have been written since in these columns on the same subject. On reading the first-named letter, I came to the conclusion that the writer, from long experience of wrongdoers, was naturally influenced in his view of the actions of gardeners in this matter. In saying this, I do not for one moment defend the principle of offering or taking what are termed discounts on business done by the employee for his employer. It is no secret that employers generally have long known there were such gifts, and have made their arrangements with their gardeners in accordance with that knowledge, taking care to rate these gifts at a much higher scale than in practice they ever reached. I know as a fact that the leading indoor servants and gamekeepers in gentlemen's places have on the average received far larger sums as "gifts" from their employers' guests than gardeners have from any outside source. All the same, these said employees were paid their salaries or wages as agreed upon when entering their several services. However, it is the future we have to face not the past. What I should like to see done is the whole thing abolished. Gardeners will never take the position their general intelligence and responsibility entitles them to as citizens until this is effected. The motto "I serve" need be no more derogatory in their case than in that of a judge of a High Court or any other position in life. To those who have reasonable employers, I would say, take a favourable opportunity of bringing the subject before them, and ask for a more fitting salary than has hitherto been paid, on the understanding that no gifts in any shape will be accepted. To employers I would say: put into practice the words many of them profess to believe in, viz., "Lead us not into temptation," by paying their gardeners a reasonable wage according to the skill and responsibility required of them. To gardeners generally I would add: try hard to become members of or subscribers to one or all of the well-known and well-managed societies, begun and carried out for their benefit, viz., United Horticultural Benefit Society, Gardeners' Royal Benevolent Institution, Royal Gardeners' Orphan Fund, and British Gardeners' Association. Allow me to quote an extract from a well-known gardener in the south, received the day before I saw Sir E. Fry's letter. He said: "There is an awful stir and bother amongst the trade and gardeners hereabouts, circulars and letters are flying about respecting discount, some saying they are sorry and some the opposite. Oh, the rottenness of the whole thing!" *H. J. Clayton, Wharfe Bank, Ulleskelf, York.*

——— W. remarks on p. 44 that gardeners are not taking Sir Edward Fry's letter on this subject in the best spirit. Allow me to inform W. that we who have been traduced in the letter in question are much the best judges as to how the letter should be regarded Our employers are given quite a wrong impression about our "honesty and morality" One thing which has surprised me in this correspondence is the curious fact that someone informs us nearly every week that the Act applies to others besides gardeners and seedsmen. Let me inform all such that we understand this perfectly—even gardeners read newspapers, but it will be quite soon enough for us to defend engineers, &c., when they have been attacked *Looker-on.*

——— Some of the facts stated in Sir Edward Fry's letter on this subject, which appeared in your columns a few weeks ago, have been adversely criticised by correspondents, some of whom occupy head gardeners' positions and no doubt are men of integrity, who make the best interests of their employers their first consideration But surely we are not expected by their arguments to be convinced that there are no black sheep in the gardening ranks, or that there are no unscrupulous members in the seed and nursery trade. I may say here that, taking gardeners and the seed and nursery trade together, compared with any other class of traders and their customers, they will compare favourably so far as men of integrity and straight dealing are concerned. But having had an experience of 12 years or more as head gardener and 26 years as nurseryman, I regard the Act as extremely necessary Some of your correspondents have mentioned that gardeners' remuneration is small; but better be poor than dishonest These remarks are not intended in any sense whatever to make an indictment against the trade or their customers, but rather to point out the fact that in the interests of the honest trader and customer, and as a preventive of the unscrupulous dealings of the dishonest, the Act was a necessity. *Nurseryman.* [This correspondence must now cease —ED.]

THE PROPOSED VEGETABLE EXHIBITION.—Considering the national importance of the Potato and its value as a food product to the civilised world, I am not quite sure if *Onlooker*, on p. 43, was quite justified when he stated that few except those interested will regret the disappearance of the Potato Society. He asks any of its late supporters of what value was it in furthering Potato culture among the masses? Certainly, *Onlooker* is justified in asking such a question. As one of those supporters, I may say distinctly that the Society did do useful work in many ways other than in the promoting of an annual show, as *Onlooker* can easily see if he will take the trouble to read up the reports in relation to the Society. No doubt five or six varieties would be ample in *Onlooker's* locality, but I doubt very much if those same varieties, which in his opinion are the best, would be as popular in other parts of the country, and, again, are his five or six popular sorts of to-day likely to be so in a very few years' time? Few things deteriorate in the vegetable world sooner than varieties of Potatos. Hence the necessity of a stimulus for the encouragement and production of new sorts. I do not, of course, pretend that all the varieties staged at an exhibition are of value from a commercial point of view, but they are all interesting, and possibly many of those having little commercial value are useful for crossing purposes. Then, as to the wrong naming or using one variety for several names. I do not say this has never been done, but as one of the judges at the late Potato Show, in which there was a good competition, my colleagues and self gave this matter our most careful consideration, and I am perfectly prepared to say that the large and important collections were not only distinct, but true to name. Is it not a fact that in nearly every special society, I care not whether it be fruit, flowers, or vegetables, there are varieties placed before the public which are of little value from a commercial point of view, but are, nevertheless, beautiful and interesting? It is merely prophecy for *Onlooker* to say that should a vegetable society be promoted, as suggested by *A. D.*, it would meet with the same fate as the Potato Society. I am not so certain as to this. On the contrary, I am of opinion that there is ample room for such a society if properly organised, one that could offer good prizes and hold its exhibition at the right time of year. *Onlooker* says that vegetables are given a prominent place at nearly all our shows, but that the visitors are little interested in them. This is not my experience. If *Onlooker* is a judge at our shows, and probably he is, let him make an example of those who stage specimens wrongly named and not in accordance with the schedule. If he knows that this practice is carried on to the extent he describes, surely he would thus be doing the general public a great service *E. Beckett.*

——— *Onlooker's* grounds for objecting to the proposed vegetable exhibition are hardly logical, as pressed to a conclusion they would equally weigh against having any shows at all. If vegetables are well provided for at provincial shows, it is idle to assume that they are so in London, the place of all others where it is needed to show the vast population what good vegetables are We have scores of plant and cut flower shows, but only one show devoted to that most important food product—fruit, and not one to vegetables. Everything for the ornamental and trivial, nothing for the essential and economic! But if it be useless or needless to encourage vegetable culture by shows, is it not equally useless to encourage plants, flowers, Roses, Carnations, Dahlias, Auriculas, Chrysanthemums, Sweet Peas, and other flowers with the aid of exhibitions? This description of argument or objection is unreasonable. As human food one good Cauliflower is worth fifty ordinary flowers, but they are not ornamental, hence they are to be counted as vulgar. *A. D.*

FLOWERING OF BAMBOOS.—In the grounds of which I have charge there are some plants of Bamboos of sorts. They have, I believe, been planted some 15 years or so, in strong, yellow loam at the back of a herbaceous border, and have done well. At the present time two or three of them are about 15 feet in height, and

have been much admired by visitors for their healthy and bright appearance. Last summer one of the best of them was a mass of flowers, but it is now losing its foliage, leaving only bare canes. I am told that they always die after flowering, and am anxious to know if this is so. *S. H. J.* [Some species die, but you have not stated which species has suffered in your garden. See an article by Mr. W. J. Benn in *Gardeners' Chronicle*, September 5, 1903, p. 169.

ONONIS ARVENSIS.—Mr. C. H. Middleton observes (*Gardeners' Chronicle*, January 18) Ononis arvensis (syn. spinosa) "succeeds best in the full sun, . . . and seldom thrives in over-moist, low ground and damp, shady places." My experience, as a result of growing both slips and seeds, under a hand glass in a soil and air kept perpetually wet, was, that in two years the plants developed no spines at all, and passed into a form closely resembling O. repens. *G Henslow, Leamington.*

SOCIETIES.

THE HORTICULTURAL CLUB.

"RECENT ADVANCES IN PLANT BREEDING."

JANUARY 14.—After the usual monthly dinner of this club held on the above date, Dr. J. B. Farmer, F.R.S., taking the chair, Mr. E. A. Bunyard addressed the meeting on the above subject, with special reference to Mendel's work, pointing out the immense advantage which the publication of the Mendelian experiments and the law of heredity which they indicated had given to selective culture of every kind, the old-fashioned guesswork with all its uncertainty and consequent loss of time and labour being now largely replaced by the knowledge that, given a conjunction of certain characters by crossing or hybridising, certain definite results were practically sure to appear in their progeny. Mr. Bunyard, in his experiments, had followed Mendel's example by selecting the Pea tribe as material, and found the results fairly confirmatory; he had, however, conceived the idea that the so-called dominant and recessive characters were not necessarily of a distinct nature. Taking for instance wrinkled and round Peas, or white, pink or blue flowers, he was of opinion that the difference was merely one of development, the wrinkled Peas being an advanced form of the round, while as regards colour it was frequently to be noted that the unopened flower buds might be of a recessive tint, and the dominant tint developing gradually as the flowers matured, passing from white through pink to bluish tint as they faded. Mr. Bunyard illustrated his remarks in a very clear manner by means of black and white cardboard discs, the black representing dominant and the white, recessive characters, each of which was present in mixed offspring either in a latent or patent form, and subsequently made their appearance in F2 or the next generation in strict conformity with the law of chance which underlies the Mendelian law. Thus if 200 wrinkled Peas, for instance, be thoroughly mixed with 100 round ones in a bowl, and taken out in pairs by a blindfolded person, these pairs would come out in definite ratios of round and round, wrinkled, and wrinkled and wrinkled, precisely in the same proportions as they would reappear by the Mendelian theory and experiments. This indeed is the logical result to be expected from the segregation of the two different character potencies existing both in the pollen grains and in the ovules of the plants concerned. In the subsequent discussion, in which Dr. Farmer, Messrs. Dunbishire, Bilney, Cuthbertson, and Dinery took part, the value of Mr. Bunyard's observations was fully recognised, and many interesting points in connection with the subject brought forward, Dr. Farmer pointing out the probable extreme complexity of the units which form what are termed characters, and Mr. Cuthbertson adding some interesting remarks about his own experiments, citing the singular fact that wrinkled Peas appeared to be correlated with lilac or purple flowers. Mr Dinery considered that much of the literature relating to the Mendelian principles ignored to too great an extent the possible disturbing influence of the spontaneous adoption of new characters due to sudden "sporting," since any tendency in this direction would be apt to upset results entirely.

Mr. Bilney referred to hybrid Orchids as evidencing in the first generation intermediate characters on very diverse lines, which on Mendelian principles should not be the case, but Mr. Bunyard considered that such cases lay outside the scope of the Mendelian experiments which dealt as far as possible with known pure forms. Dr. Farmer, in conclusion, pointed out the great value of such meetings in bringing together the scientific and the practical man, each being thus able to profit by the knowledge of the other to the mutual benefit of both.

LONDON DAHLIA UNION.

JANUARY 15.—The annual meeting of this society was held in the Horticultural Club Rooms on the above date, Mr. John Green presiding. The secretary having read the report and balance-sheet for the year ending December 31st, 1907, it was unanimously approved and adopted.

EXTRACT FROM THE REPORT.

Though only constituted as a Society in 1904 your Committee are gratified to report that the result of the year's working has been of a most satisfactory nature.

The Annual Exhibition was again held in the Gardens of the Royal Botanic Society at Regent's Park. It was generally acknowledged by all who visited the show to be the finest yet held under the auspices of the Union.

It is satisfactory to note that at the end of the year's working the Union has a balance of assets over liabilities amounting to £11 6s. 8d., and thus after carrying on a bolder propaganda for bringing the work of the Union before the notice of the Dahlia loving world.

Your Committee are at present unable to state definitely the place and date of the Exhibition for 1908. They are at present in negotiation with the various authorities in regard to same and will decide the matter as early as possible.

Mr. John Green was re-elected president for the ensuing year, and the retiring members of the committee, Messrs. Caselton, Cuthbertson, Gordon, and Mortimer were also re-elected.

The following officers were re-elected: Mr. W. Stephens (treasurer), Mr. E. F. Hawes (secretary), and Mr. R. Ballantine (auditor).

It was decided to offer two Gold "Dean" Memorial Medals for Pompon Dahlias in 1908, one in the trade section and the other for amateurs.

On the motion of the treasurer, Mr. W. Stephens, seconded by Mr. J. T. West, a honorarium of £5 5s. was voted to the secretary, Mr E. F. Hawes, for his services in connection with the union during the past year.

The president, Mr. John Green, informed the meeting that he had arranged to carry out a large trial of Dahlias in all classes at Dereham, during the present year, and gave the members an invitation to appoint a deputation to inspect and report upon these trials. This was cordially accepted, and the selection left to the committee.

It was also resolved to hold the annual meeting in January instead of December as formerly, and that in future all meetings be held on Monday afternoons at 3 p.m.

SOCIÉTÉ FRANCAISE D'HORTICULTURE DE LONDRES.

ANNUAL DINNER.

JANUARY 18.—A representative gathering of members and friends took place on the above date at the Cafe Royal, Regent Street, to celebrate the nineteenth anniversary of the foundation of this useful and flourishing institution. Mr. Harry J. Veitch occupied the chair, and among the numerous company present we noticed Messrs. Edward Sherwood, George Schneider, M. Lagear, M. Delanone, M. Huguenet (editor of *La Chronique*), Messrs. George Gordon, R. Hooper Pearson, G. J. Ingram, J. McKerchar, W. Howe, T. Bevan, J. H. Witty, J. Weathers, F. Such, D. Ingamells, B. Wynne, J. Gaskill, and others.

The speech of the evening was that of "La Société Française d'Horticulture de Londres," and the chairman, in the most cordial manner, expressed his pleasure at being invited to preside over the meeting. He had many pleasant recollections of France, and his relations with Frenchmen had always been of the most agreeable nature. For many years he had watched the progress of the society, and he was pleased to find that it now numbered 700 members. It had therefore, assumed an importance beyond question. He was proud to think that the young Frenchmen who came to this country thought they could learn something to their advantage, and whatever they did learn he hoped would be of profit. The rules were admirable and gave every satisfaction. He found that although his firm was included among the life members, yet he himself was not, and he would take it as an honour if they would accept him in that category. Mr. Veitch said that during the past 50 years progress in horticulture had been extraordinary. He then gave some interesting details concerning the improvement of Crotons, Dracænas, Orchids, Caladiums, Begonias, &c., rendering homage to the efforts of French growers such as MM. Maron, Bleu, Lemoine, and Schneider, the latter of whom was the first to raise hybrid Ferns. In many things, said the chairman, we have obtained much from France, and we owe a debt of gratitude to her for our knowledge in various respects. The young men of to-day will have to step into the places of their elders, and it will behove them to use their opportunities to the best advantage. Competition is keen, and the chairman of last year reminded them that American Apples are rapidly invading the markets of Europe. To keep to the front they would have to study horticulture thoroughly and to work hard. He hoped they would bear that in mind, or they would not succeed. He did not believe in all work, but it must be work first, and when that is done they could then enjoy pleasure. He was glad to express thanks for much kindness received in France. Fifty years ago he was there with Messrs. Vilmorin, who were kindness itself, and the same might be said of all the others whose nurseries he visited; especially did he remember Thibaut and Kitleet, Vetmer, Chantin, Margottin, and Truffaut. He was glad to testify that round Orleans, too, he was, although a mere youth, most cordially received, and he had never forgotten it. Personally he would always be pleased to help them or their friends. He had pleasure in proposing continued and increasing success to the society, coupled with the name of their president, Mr. George Schneider.

Mr. Schneider replied, thanking Mr. Veitch for the kind words he had used towards France. Mr. Veitch's kindness to the young foreigners in his employment was proverbial. The visit of the society to his residence at East Burnham would not be easily forgotten, nor the hospitality that their chairman had so generously offered them on that occasion. Owing to his kindness they had largely been enabled to found and maintain the society, hence he had a double claim on their consideration as chairman that evening. The success of the society was also in a measure due to those English friends and supporters who find employment for their young men, who, as M. Ph. de Vilmorin reminded them two years ago, are not rivals nor competitors, but pupils who come to learn our language and methods, and return home there to help in maintaining the good relations that have always existed between the horticulturists of the two countries. "Success to English Horticulture" was then proposed by Mr. Schneider.

The reply came from Mr J. McKerchar, who explained that he was neither English nor French. As some of the speeches were in French, Mr. McKerchar hinted that he could have replied in a language that probably no one present could have understood. If this were Gaelic, our reporter is grateful for his forbearance. He concluded by proposing the toast of "Past Chairmen."

Mr. Harman Payne, one of the oldest English members of the society, replied. He regretted they had recently lost one of their number by death, Mr Arnold Moss. Another who had promised to be there, M. Philippe de Vilmorin, was detained in Paris owing to the serious illness of his mother. They were pleased, however, to see several others present, notably Mr. Bevan and M. Lageat. All the past presidents were glad to hear of the continued progress of the society, and to count themselves among the friends of their devoted president, Mr Schneider, whose recent decoration by the French Government was a proof of the appreciation of his services to the society and to horticulture generally. In his work he had been helped by his brother

officers, one of whom, M. Ripard, had kindly undertaken the floral decoration of the tables, for which their thanks were due. On behalf of the officers, M. Ripard replied.

The toast of "The Horticultural Press," proposed by the last speaker, was responded to by Mr. George Gordon, and M. Lageat having proposed "The Chairman," Mr. Veitch, in acknowledging this toast, proposed "The French Press." The editor of *La Chronique*, M. Huguenet, alluded to the forthcoming Franco-British Exhibition and the gradual drawing more closely together of the two nations.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

JANUARY 23.—The annual meeting of this Institution for the Election of Pensioners is being held on Thursday afternoon as these pages are sent to press.

RESULT OF ELECTION.

There were 52 candidates, and the nineteen whose names are given below were successful:—

	Number of Votes.
James Mack	3,671
William Cookson	3,455
William Swanborough ...	3,307
George H. Green	3,073
James Chesher	2,972
William Edwards	2,797
Robert McAdam...	2,788
Mary Manderson	2,633
Euphemia Clinging	2,543
John Stanton	2,535
Nehemiah Blandford	2,498
George Little	2,496
Thomas J. Foote	2,481
Ann J. Solman	2,452
William Pooley	2,426
Charles Kinns	2,360
Robert Maher	2,357
Alexander Clark	2,338
William Moore	2,370

In addition, the following candidates were elected by the general meeting on the recommendation of the Executive Committee:

Susan Hale. William Jones.

Owing to the liberality of Mr. Arthur W. Sutton and Mr. George Monro, the candidates, Thomas Jones and Laura Stockwell, were granted one year's pension each.

THE SURVEYOR'S INSTITUTION.—The next ordinary general meeting will be held on Monday, January 27, at 8 o'clock, when a paper, entitled "Some Urban Land Problems," will be read by Mr. A. W. CRAMPTON (Fellow). The annual dinner of the Institution will be held at the Whitehall Rooms, Hotel Metropole, on Wednesday, February 26, at 7 o'clock precisely.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending January 22.

Another sudden change in temperature. The first three days of the week were exceptionally warm for the middle of January—usually the coldest period of the year, but since then a return to cold weather has taken place. On the warmest day the temperature in the thermometer screen rose to 53°, or about 12° higher than is seasonable, whereas on the coldest night the exposed thermometer registered 14° of frost. The ground is still cold, the temperature at 2 feet deep being 1°, and at 1 foot deep 2°, colder than is seasonable. There has been no rain or snow worth mentioning for nearly a fortnight, consequently no measurable quantity of rainwater is now coming through the percolation gauges. The sun shone on an average for 1 hour 47 minutes a day, which is about the average duration for this part of January. On four days no sunshine at all was recorded, but, on the other hand, on one day the sun was shining brightly for nearly six hours. On the first three days the wind was rather high, but since then calms and light airs have alone prevailed. The mean amount of moisture in the air at 3 o'clock in the afternoon exceeded a seasonable quantity for that hour by 5 per cent. On two days the air remained saturated with moisture throughout the whole day, and on one morning there was a thick fog. The Winter Aconite came first into flower on the 20th, which is its average date for the previous 21 years, but three weeks earlier than last year. *E. M., Bekkamstad, January 22, 1908.*

MARKETS.

COVENT GARDEN, January 22.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

REMARKS. Large consignments of Apples have arrived from Canada and Nova Scotia this week, consequently prices for most varieties are considerably lower. There is a decided improvement in the demand for English Grapes, and prices are generally dearer. Oranges are scarcer, especially of the finer grades from Denia and California. Bananas that have not been frosted are selling well. The trade for Cut flowers continues to be good. Tomatos from Teneriffe are now showing signs of "waste," with no result that "sound" packages are dearer. *Covent Garden, January 22, 1908.*

Potatos.

Kents: Up-to-Date, 100s. to 110s.; British Queen, 100s. to 105s.; Scottish Triumph, 100s. to 105s. per ton. **Lincolns:** Up-to-Date, 100s. to 115s., Up-to-Date (Blackland), 90s. to 95s.; British Queen, 95s. to 105s.; Sir Jno. Llewelyn, 90s. to 100s.; Royal Kidney, 85s. to 95s.; Evergood, 85s. to 95s.; Minerop, 110s. to 115s. per ton. **Dunbar:** Up-to-Date, 120s.; Maincrop, 130s. per ton. **German:** Up-to-Date, 4s. 6d. to 4s. 9d.; Magnum Bonum, 4s. 6d.; Imperator, 3s. 9d. to 4s. per bag. **Dutch:** Up-to-Date, 4s. 3d. to 4s. 6d.; Magnum Bonum, 4s. 3d.; Imperators 3s. 9d. to 4s. per bag. Trade is quiet, with much heavier arrivals. In consequence prices lower. *F. J. Nicoborn, Covent Garden and St. Pancras, January 22, 1908.*

COVENT GARDEN FLOWER MARKET.

The mild weather on Monday tempted some growers to send to the market Cinerarias and other tender plants, but 10 degrees of frost were recorded on Tuesday morning, and this checked the trade for such plants. Indian Azaleas are now a prominent feature, and are very good as received from several growers. Genistas are fairly well flowered. Erica hyemalis holds out well, but is not quite so good as it was a few weeks ago. E. gracilis and the tall pyramidal plants of E. melanthera are well flowered. Lilium lancifolium rubrum in pots is very good. L. longiflorum is scarce. Daffodils Golden Spur and Telamonius plenus (Double Van Sion) are now plentiful. Spiræa japonica and S. Astilboides floribunda from retarded crowns are well flowered. Begonia Gloire de Lorraine is not quite so plentiful just now. Cyclamen are being sent by several growers, but the quality is variable. Marguerites are not quite so abundant. Dutch Hyacinths in white, pink, and pale blue shades are plentiful, all are now grown with three bulbs in each pot. Roman Hyacinths are very good. Tulips in boxes, in all colours are excellent this season. Ferns are well supplied in all sizes. A. Sieboldii and the variety Moseri are plentiful in well matured plants, but some with soft new leaves are seen, these do not withstand the cold. Many imported plants of Dracæna australis are present.

CUT FLOWERS.

Daffodils are now coming from various sources. The English-grown flowers of Golden Spur, Henry Irving, and Double Van Sions are very good. Prices are maintained fairly well. Tulips being over-abundant, the prices have fallen. Couronne d'Or is very fine from several growers. This Tulip sells at better prices than almost any other variety. Tournesols are very good. Most of the single varieties now seen have fairly long stems, but others have short ones, and these latter are offered at low prices. Liliums vary but little: flowers of the best quality are not over plentiful. Prices for Carnations are lower. Chrysanthemums are holding out well, and are now making good prices. Roses are rather more plentiful. Catharine Mermet and Bridesmaid are the best pink varieties at the present. Callas have been selling at prices varying from 4s. to 7s. per dozen. Imported flowers have fallen off a little. Good paper-white Narcissus have increased in price to 3s. per dozen bunches, and Soleil d'Or, to 4s. or 6s. Mimosa (the true Acacia dealbata) is now very fine. *A. H., Covent Garden Market, Wednesday, January 22, 1908.*

TRADE NOTICE.

MR. H. JESKINS, for the past 8 years Gardener and Steward to F. RAINES, Esq., Southmoor, Acaster Malbis, York, has been appointed Nursery Manager to Messrs. MICHIE & Co., Alnwick.

ENQUIRY.

SPOTTED ASPIDISTRA.—I have seen an Aspidistra with ordinary green leaves, except that they are spotted with creamy-white spots not much larger than a pin's head. Some leaves are variegated in the ordinary way, but the majority are spotted, otherwise the plants, of which there are four, are perfectly similar to the type. The plants have been under the cultivator's observation for seven years. Is this variety rare? *T. C.*

Answers to Correspondents.

APPLE. *W. P.* The injury has every appearance of being the result of frost.

CODIÆUMS (CROTONS) LOSING THEIR LEAVES: *A. L.* Without knowing the exact cultural conditions, it is difficult to advise you in this matter. It is certain, however, that the plants are suffering from a check, and this may have been brought about by a variety of causes, such as too little atmospheric warmth, an overdose of manure, sulphurous fumes from the stokehole, dryness at the roots, &c. A healthy Croton requires much water, and if extra firing has to be done to keep up the necessary degree of heat the plants should be examined daily. As you cannot replace the leaves, the plants should be cut back and the roots kept rather drier until new growth appears, after which time, if given good cultivation, they will soon form decorative plants. Crotons require a minimum atmospheric temperature of 60° all through the winter.

CELOSIA. *J. G. F.* So far as we can judge from your letter it would be difficult for the fumes from the blocks to enter the house, but this matter you must determine for yourself. If they could escape into the house, and the blocks have been recently been creosoted, you may depend upon it the plants would suffer. It would be wise to employ blocks that were creosoted some months ago.

GRAFTING OF PLUM TREES: *A Twenty Years' Reader.* If the weather is not frosty you may head your Plum trees back at once, for if left until the sap commences to rise they would bleed in consequence. If you saw off the tops cut the part over afterwards with a sharp knife. No time should be lost in cutting the scions; it is a much better plan to do this early than to leave them until they are required, when probably the buds would have started growth; the consequent check then given them might entail their loss. In selecting grafts secure good, firm shoots, and lay them in the ground about 9 inches deep in the manner you would plant a cutting, treading the soil firmly about them to exclude air. The best method of grafting your trees would be that known as "crown" or "rind" grafting, and illustrations of this method have often been given in *Gardeners' Chronicle*. The operation should be commenced when the sap is found to be rising, and such branches as were previously shortened back to within 18 inches to 2 feet of the main stem, if measuring 6 inches or more in diameter may have three grafts placed on each. Commence by making a longitudinal cut with the point of the knife down the bark about 3 inches to 4 inches long; this length gives the branches more power to withstand wind, &c., than a shorter graft. Next take the graft, which should be about 7 inches long, and cut it in an oblique manner and the same length as the longitudinal cut in the bark. By gently easing up the bark on the stock with the knife the graft may be pushed down into position, and should then be tightly bound with raffia or soft twine, and covered over either with clay or grafting wax, so as to effectually prevent the entrance of air. It is advisable to place moss over the clay, to prevent it from becoming so dry as to crack and fall. The best kind of clay is that which has been ground up at a brick yard. With each barrow load of clay mix one bucketful of fresh cow manure. There is a book, translated from the French of De Breuil, which treats fully on the process of grafting, and may be had from our publishing department, price 3s. 8½d., post free.

HONEYCOMB. *T. G. H.* There is nothing abnormal about the colour of the sample comb. The scent is unusual, but may be caused by the peculiar aroma of the nectar gathered. It would have been better had a sample of the honey been sent in the comb. Pieces of comb are often built in spaces similar in shape to those received. We should think you are labouring under a mistake about the amount of wax a hive ought to contain, for there is not more than a pound to be obtained from 10 frames of comb. You ought not to have opened the hive at all since the beginning of October; by so doing you have allowed heat to escape, and the bees have probably died from exposure to cold. They are naturally in a condition similar to that you describe. If the bees were not fed sufficiently to nourish them through the winter, that is, with syrup, they should have been given candy, and made quite snug and left alone. No honey should have been taken from the hive. There does not appear to be any disease, but, to be on the safe side, wash the hive well with a disinfectant and expose it to the atmosphere before using it again.

IRISES: *C. Day.* The position you describe would answer very well for Iris Kæmpferi, this species succeeding best when treated as marsh or semi-aquatic plants. Slight shade should be afforded the flowers by trees or bushes, because the large outer segments of the flowers are not capable of withstanding the hot sun for a long period. A variety with deep blue flowers is Blue Bird, and if you require a combination of blue and yellow in one flower, Charmer may be selected. Gold Bound is the variety nearest approaching a good yellow; but all the varieties are so beautiful, that in order to see them at their best a collection should be cultivated. In such a position as you describe, a very pretty Bog garden could easily be formed, and it would constitute an attractive feature of the garden. Many plants will winter in your locality (Truro) that would perish in less favoured districts.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. ***Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*** **PLANTS:** *Horton.* 1, Oncidium carthaginense; 2, Zygopetalum intermedium.—*Fernside.* Cymbidium giganteum, and a very good variety of this species. Its flowers also having been produced in a cool house are darker than when the plant is grown warmer.—*J. K.* We cannot undertake to name varieties of Violets.—*R. H., Hampstead.* 1 and 2, Varieties of Hedera Helix; 3, Gnaphalium sylvaticum; 4, Carex sp. (insufficient material for identification); 5, Luzula sylvatica.—*F. S.* Ruellia Portellæ.—*T. A.* 1, Odontoglossum Andersonianum; 2, Odontoglossum gloriosum; 3, Oncidium cheirophorum; 4, Tetramicra bicolor; 5, Octomeria diaphana.—*F. D., Northampton.* 1, Reinwardtia trigyna, commonly known in gardens as Linum trigynum; 2, Scolopendrium vulgare; 3, Nephrodium molle; 4, Pteris cretica albo-lineata; 5, Blechnum occidentale; 6, Cyrtomium falcatum.—*G. C., Exeter.* Salvia leucantha.

PALM SEEDS: *F. Colman.* It is not possible to name the seeds received with any degree of certainty. We do not think they possess much commercial value, and two kinds out of the four received are worthless, being already dead.

RHODODENDRONS (AZALEAS) LOSING THEIR LEAVES: *R. M.* The fact that your imported Azaleas continue to lose their leaves since being potted points to the plants having suffered a severe check. A probable reason would be that the plants, after being lifted, were unduly exposed at some time, with the result that the fine roots became very dry; this in itself would be sufficient to cause the injury. If this condition was unnoticed at the time of potting, the roots of the plants may suit that the fine roots became very dry; pear sufficiently damp. Writers of the weekly Calendar on "Plants Under Glass" have frequently drawn attention to this important detail. On the other hand, over-watering would also cause the leaves to fall. Azaleas, like all hard-wooded plants, require extra care in the matter of watering, extremes in either case being detrimental to the health of the plants.

SOBRALIA LEAVES DECAYED: *G. J. H.* If the leaves sent are from the old stems, they are merely passing off in the usual way. But if they were taken from the newest growth, they may have been affected by a sudden and temporary fall in the heat of the house to too low a degree at some time. Insufficient pot-room or drought at the roots might produce a similar effect. Sobralias are among the easiest of Orchids to cultivate. They require abundance of water while making their tall reed-like stems. Removal to a vinery or other tolerably cool house for a period following the flowering stage is beneficial to the plants.

USES OF THE MOTOR IN HORTICULTURE.

NO great industry can live which is entirely dependent upon the pleasure-loving tendency of the nation. There must be some material benefit gained, either directly or indirectly, and upon this foundation only can the support of the public be retained. It is more usual for an amusement to evolve out of a provision for a necessity than for the necessity to become apparent when catering for an amusement.

Whatever might have been the objects aimed at by the pioneers of the bicycle and the motor industries, they certainly first catered for a fashionable pleasure, and now, in the case of the bicycle, it is almost entirely purchased on account of its utility, whilst the industrial motor is rapidly asserting itself as being an indispensable part of the equipment of every business.

When opening up a new country, attention must first be given to methods of transport. However fertile a country may be, however rich in minerals, cheap the labour, or well supplied with natural power for driving machinery—all these are without value unless the means of transport are good, and the want of these facilities has led to the abandonment of many rich tracts of land, rich in everything but means of transport. Robinson Crusoe is not the only instance of a man who, having built a boat, has been unable to launch it!

Transport facility is the fundamental basis of the prosperity of countries, counties, or districts. In England we have, it is true, unequalled systems of railways and roads and good canals, but still there is something lacking. The railways are excellent for passenger and nearly all classes of goods traffic. The roads form the medium by which the railway station is reached. The canals can only be regarded as a means of transporting, at a minimum cost, such heavy commodities for which accelerated delivery is not essential.

Something intermediate between the railway and horse transport by road, which would bring hitherto isolated districts again into the front ranks of industry, and into fair competition with their more favoured neighbours, has for many years been needed. There can be no doubt that the industrial motor at length solves this difficulty, and its general adoption will only be a matter of time.

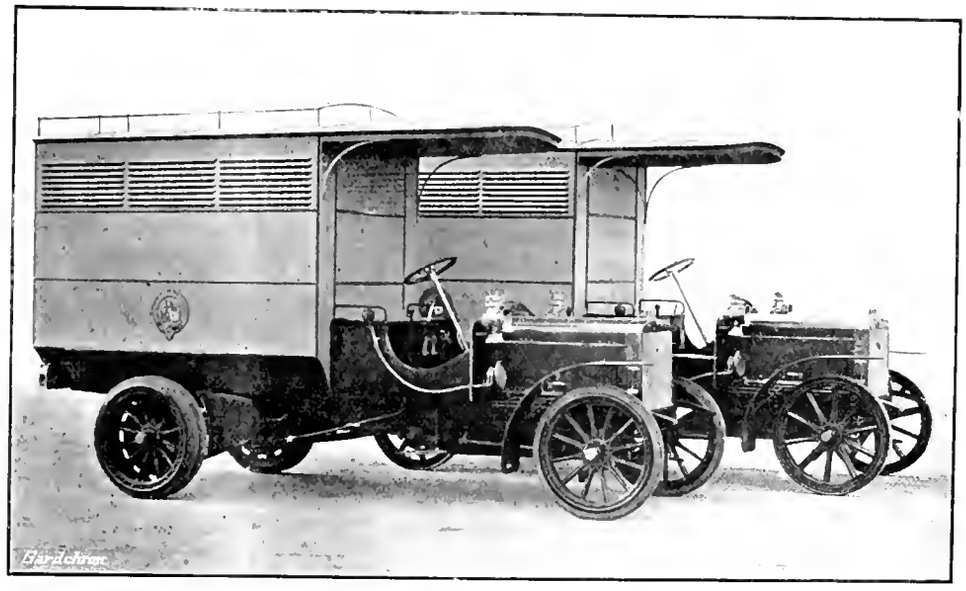

FIG. 32.—MOTOR DELIVERY VANS FOR NURSERYMEN; ONE WITH SOLID RUBBER, AND ONE WITH IRON TYRES.

It is not so much the improvement of the motor that is now required to gain its popularity, as a more general knowledge of its mechanism and management. That there will be improvements in the design of the industrial car is certain, but even to-day it is sufficiently reliable to make its use far more economical than horse traction, and to render its owner, in a great measure, independent of railway companies.

To nurserymen, florists, and market gardeners, it will no doubt prove itself to be of the very greatest value. These industries are essentially field industries, but up to the present it has been very necessary that the ground under cultivation should be in close proximity to a market town or railway station. For this reason the site is often chosen more because of its locality than for the natural advantages offered by the soil. Cultivation combined with expenditure will, of course, put the latter fault right. But the first cost of the land must also be large, and, if held under tenancy, the rent must be high, for any such land as this comes under the category of "accommodation" land. But the produce must be marketed quickly, therefore it is better to pay for the site than to lose more than its value in loss of sales. In addition to this, should the selected town or city be one of prosperity, as the population increases the owner must be continually questioning himself as to whether the land would not yield him a more lucrative income under buildings than under cultivation. That such a time does arrive is evident to everyone who is familiar with the suburbs of large cities. Around London this is very noticeable, though the demand for garden produce is greater there than it has ever been.

No one suffers more at the hands of railway companies than the market gardener; his goods are perishable and are easily damaged, therefore they must be handled quickly and with care. Special vans must be built to meet the requirements for flowers and delicate fruit. The railway rates are proportionately high; but the question is: Does the grower get the value for his money? It would seem that he does not, if we may judge from what happens in years when fruit and flowers are plentiful. In such years as these it is found that the sale of the fruit does not pay the expenses of gathering and placing it on the market. Yet even in the height of our fruit season hundreds of tons of foreign fruit and flowers are imported and sold. This anomaly must surely be due mainly to the cost and conditions of carriage.

These difficulties have been mentioned in order that the utility of the motor may be more readily understood. It means that the enterprising grower, having adopted the motor vehicle, need no longer be tied to certain districts because of the special facilities of the railway services offered. He need not pay high prices for land in such districts; but he may choose his ground anywhere within a 50-mile radius of the market he wishes to serve, or in a central position within reach of several markets.

He may select a vehicle suitable to the requirements of his business, and, to a great degree,

suitable to the price he can afford to pay. There is not, however, very much difference in the prices of the best makes having equal load capacity and of similar design.

For loads of over 3 tons there is nothing yet placed on the market that can compare with the 5-ton steam waggon, both for moderate first cost and economy in working expenses. A vehicle of this description may be purchased for £500, and another £75 will be all that is necessary for accessories, including the cost of a trailer. The latter may be dispensed with if the purchaser has a horse van he is able to spare in cases of emergency. The shafts may be taken off this and replaced by the trailer bar for attachment to the back of the steam waggon.

To a limited extent these vehicles are already used for bringing garden produce into Covent Garden Market, and there can be no doubt that, once the growers are fully alive to the great saving which is possible by this form of transport, they will become increasingly popular.

The main difficulty lies in finding a sufficient amount of traffic to keep the vehicle employed throughout the year; but even should it be necessary for it to remain idle for a certain portion of the year, there would be nothing with which to debit it but the interest on the capital invested—a trifling amount as compared to horse maintenance during slack times. The greater convenience and saving in time and cost will amply repay users for any limited periods of enforced idleness. *Hugh Miller, C.E., M.E.*

(To be continued.)

NEW OR NOTEWORTHY PLANTS.

COLUMNEA MAGNIFICA.

THE figure of this splendid species—by far the finest yet introduced—was drawn from a specimen communicated for the purpose by Mr. W. E. Gumbleton, of Belgrove, Queenstown, who has been very successful with it. Although discovered about sixty years ago in the province of Veraguas, Panama, by the well-known collector of Orchids and humming-birds, Julius von Warscewicz, who brought back dried specimens of it which were described by the Danish botanist Oersted* in 1858, C. magnifica was not known in cultivation till 1906, when it was introduced by Lemoine, who received it from Carlos Werckle, a collector in Costa Rica. We are indebted for the collector's name to Mr. Gumbleton, who, in answer to our enquiries, has kindly supplied the following information:

"Columnea magnifica grows freely in an intermediate house, and is now flowering freely in my conservatory, from which frost is just kept out by an ordinary circumambient flue. Its brilliant flowers remain in beauty of freshness for many weeks, which adds much to its value as a decorative plant. . . . It strikes readily from cuttings, which bloom in quite a small state and soon make nice plants. My tallest stem is 15 inches in height. I received it from Lemoine in February, 1907."

The closest ally of C. magnifica is C. rotundifolia, Salisbury, *Paradisus Londinensis*, t. 29. The latter plant was subsequently figured as "Columnea scandens" in the *Botanical Register*, Vol. x., t. 805, and *Botanical Magazine*, t. 1614,

FIG. 33.—COLUMNEA MAGNIFICA: FLOWERS FLAME-COLOURED.

and is still cultivated under that name in England. The true C. scandens, however, which is figured in *Botanical Magazine*, t. 5118, differs from C. rotundifolia, not only in the nature of its calyx and corolla, but also in its geographical distribution. Full synonymy of the two species may be found in Urban's excellent account of the West Indian Gesneraceæ,* and we shall therefore confine ourselves to a very brief comparison.

C. ROTUNDIFOLIA.—Pedicels and base of calyx covered with purplish hairs; calyx-lobes acuminate from a broadly triangular or ovate

* Centralamericas Gesneraceer ved A. S. Oersted, Kjobenhavn, 1858.

* J. Urban, Symbolæ Antillanæ, Vol. ii., p. 360 (1901).

base, deeply toothed. Native of St. Vincent, Grenada, and Trinidad.

C. SCANDENS.—Pedicels and calyx with dirty whitish hairs; calyx-lobes linear-lanceolate or subulate-lanceolate, entire or only slightly toothed. Native of Dominica and Martinique.

The disc of C. magnifica is represented, just as in C. rotundifolia and C. scandens, by a single posticous gland only, which differs, however, in being emarginate instead of entire.

In retaining the name Columnea magnifica for the species introduced by Lemoine, we have relied on its general agreement with the description given in Hanstein's *Monograph of the Gesneraceæ*,* which differs in several respects, however, from the original description by Oersted; there is just a possibility, therefore, that Oersted and Hanstein had different species before them, and it seems desirable, on that account, to enumerate the chief differences in the two descriptions:—

OERSTED.	HANSTEIN.
1. Leaves very shortly petioled.	1. Leaves shortly petioled.
2. Stem tomentose.	2. Stem hirtose-villose
3 Calyx tomentose.	3 Calyx hirtose-villose.
4. Lateral corolla-lobes hardly united to the hood (galea).	4. Lateral lobes less united to the hood than the two lobes of the hood are to one another.

Differences 2 and 3 might be simply due to a different application of technical terms; but 1 and 4 are more difficult to reconcile, for one could hardly call the leaves of the plant now in cultivation "very shortly petioled," or state that the lateral lobes of the corolla are "hardly united" to the upper! The lateral lobes are united, as a matter of fact, for more than half their length, and the leaves have a very respectable petiole, as petioles go in Gesneraceæ (see fig. 33).

The position then is as follows: if we are right in assuming that Hanstein described the same species as Oersted, then Oersted's description is very inaccurate; if, on the contrary, Oersted's description be a good one, then the plant which we now have in cultivation is a new species. The matter can only be settled by examination of the type specimens, which are not in this country.

In conclusion, we may give a short description of the species now in cultivation.

COLUMNEA MAGNIFICA, Hanstein, in *Linnæa*, xxxiv., 401 (Oersted ?).—Stem erect, attaining a height of 1 foot or more, hirsute-villous, as are also the petioles and pedicels. Petioles under half an inch long; blade of leaf oblong to oblanceolate, acute, obscurely serrulate, 1 to 2½ inches long, ¼ to ¾ inch broad, roughish with appressed hairs all over the upper surface, hairs mainly confined to the veins on the lower surface. Flowers axillary, solitary or two together, borne on the upper part of the stem. Pedicels ½ to ¾ inch long. Calyx densely villous at the base; lobes lanceolate, serrate, over ½ inch long. Corolla flame-coloured 2½ inches long; tube 1¼ inch long; lower lip consisting of a single lobe, reflexed when the flower is fully expanded, linear-lanceolate, ¼ to 1 inch long; upper lip consisting of the lateral lobes and the completely united posticous lobes (= hood); lateral lobes spreading, adnate to the hood for more than half their length; hood arched, entire. Gland of the disc solitary, posticous, emarginate. Ovary villous. Native of Costa Rica (and of Veraguas, Panama, according to Oersted).

It will be noticed that none of the flowers in the accompanying illustration are fully expanded; in the completely opened flower the anterior corolla-lobe points nearly straight downwards, and the lateral lobes are very spreading. The writer, when examining a specimen presented to the Kew Herbarium by Mr. Gumbleton, kept it in water for over a week without any signs of flagging, and was able in consequence to observe the fully developed flower.

* *Linnæa*, Vol. xxxiv., p. 401.

One view of the pollen grains is well shown at the right-hand bottom corner of the illustration, namely, as they appear when dusted dry on to a slide. Other views (which may be seen on examination in water) show them circular or trigonous. *T. A. Sprague.*

FORESTRY.

THE LARCH APHIS AND BLISTER.

SIR HERBERT MAXWELL misapprehends the word "suffice" in my former letter. I meant that the Dumfriesshire case sufficed as an example of the blister following aphis in a most suggestive way. Sir Herbert complains that "I did not give a single detail." I stated that from what I saw and was told the trees were free from disease up to a considerable age, to about 20 feet high, as I judged; then the aphis came and the disease followed the aphis quickly. That was a detail, indicating both "cause and effect," and if it could be confirmed in a sufficient number of cases, as I think it could be, it would suffice. "Soil and aspect" were there before and after the disease and may be eliminated, as may also Sir Herbert's "conditions" at p. 51 which the plantation had long survived.

Assuming that I have stated the facts correctly, can Sir Herbert explain the attack otherwise? The formation, I think, was whinstone, and distance between the trees about the usual thing after thinning.

As to constitutional vigour resisting the disease, what does Sir Herbert call "vigour" in the Larch? I offer no dogmatic opinions, but some of the worst diseased plantations I have ever seen were amongst the most vigorous also, the growth being 3 feet 6 inches to 3 feet 10 inches annually. I am almost convinced that a Larch that grows at a moderate pace and ripens its wood well, resists disease best, and it was the disease called "gumming," or blister, in certain stone fruits, like the Peach, that first caused me to think so. "Gumming" is caused by a fungus similar to the Larch fungus in its nature and action [?], and it is always worst on the most vigorous but ill-ripened trees. Well-matured wood is a preventive. Most gardeners know that.

The late John MacDonald, forester to the Duke of Athol, in his evidence before the Committee of 1887, firmly "held" to the belief that blister was caused by the aphis, and few had longer or better opportunities of knowing. He repeated that opinion to me at Dunkeld, and was emphatic about it, because the one followed the other (see Blue Book, 1887, p. 52). Sir Herbert Maxwell's opinion that the freedom of the Japanese Larch from disease is due to its vitality is not borne out by the facts so far. If it was a case of comparative vigour, the Japanese species might be expected to suffer in a less degree only, but it is immune as far as is yet known, and there are weak plants in all plantations of the Japanese species as well as among the common Larch.

The recorded cases of disease in the Japanese Larch need vouching for. I know the principal plantations in England and Scotland, but cannot procure a diseased example. The two most important cases ever published, and vouched for by two teachers of forestry in well-known universities, never existed, and the other so-called cases have not been vouched for. One may sometimes see slight gumming on Japanese Larches as on other trees, when injured by a shot or something of that kind, but the fungus cannot be found, search as you may. Gumming exudations may often be seen on the common Larch where there is no fungus, and the casual observer calls these disease. I should feel obliged by anyone sending me a little slice of bark showing the Larch fungus at the cup stage on the Japanese Larch, and they ought to be capable of being found at this season if they exist. The more one sees of the Larch disease the more unsettled their convictions become. I would like to know to what extent the disease is found to prevail on iron impregnated soils. In parts of Yorkshire, where iron-stone and coal prevail, the disease is seldom very destructive in my experience, and on the Wealden clay in Sussex, largely impregnated with iron, it is the same. The cleanest skinned Larch, at the disease stage, I have ever seen were in Sussex in pure Larch plantations grown for Hop poles 2½ and 3 feet apart, and they had been stripped of their lower branches with a knife making numerous wounds. The bark in these cases was remarkably smooth and clean. There seems to be no doubt that the disease is assisted by outside influences, but the real resisting power seems to be within the tree, wherever the power is derived from. *J. Simpson, Sheffield.*

FLORISTS' FLOWERS.

WINTER-FLOWERING CARNATIONS.

A NOTE on Tree Carnations appeared in a recent issue of the *American Florist*. The writer, Mr. C. W. Johnson, evidently a commercial grower, a specialist working on American lines, and therefore putting his plants on "benches" instead of potting them as we should do, after assuming that the early-planted and indoor-grown plants had now reached that stage when an occasional application of a fertiliser will greatly benefit them and stimulate their growth, goes on to say that the stems and calyces of the flowers are good guides in applying manures to Carnations. If the stems have begun to stiffen greatly, and to be brittle and break off at the nodes with the lightest touch, and the calyx of the flower to split, these are trustworthy signs of over-feeding, and the cultivator should be guided accordingly.

The condition of the plants should determine whether to make the application in liquid form, or to add it to the soil as a surface dressing. If the plants show many buds and shoots on the verge of forming buds, the plants will be greatly benefited if the manure be given in liquid form. The application of a fertiliser at this stage of growth increases the size of the blooms without causing them to diminish their substance or spoil their texture. The fertiliser should therefore be of moderate strength, and as often applied to the soil as this can be done without causing a soddening of the latter. When much fire-heat has to be employed to keep out frost, as is the case in the northern United States, the soil of which the beds consist should be examined down to the bottom, in order to find out its condition of the soil as regards its moisture. Liquid manure should not be applied to the plants when the soil about their roots is at all on the dry side, but clear water instead, allowing the plants time to absorb it before applying manure water, in order to prevent them absorbing a dangerous quantity of the latter. The substances best suited for making liquid manures for Carnations are cow, sheep, and chicken dung, the first two in the proportion of half a bushel to a barrel of water, and of the last named a quarter of a bushel will be a safe quantity. A small quantity of fresh soot and bone meal will increase the fertilising properties of the cow and sheep manures. If these manures are not applied by a pump and hose, but with the watering pot, it is an easy matter to add clear water in the pots if it be considered of too great a strength. Backward plants may be assisted by light top-dressings of powdered sheep's dung, bone meal or wood ashes scratched into the soil, care being taken not to afford so much as to cause soft growth.

Stock plants from which large quantities of cuttings are expected should be afforded nitrogen very sparingly, or the grass cuttings will emit roots with difficulty.

SPECIMEN PLANTS FOR VASES AND TUBS.

THE furnishing of terraces adjacent to the mansion and other positions of prominence in the garden during summer with tubs, vases, or similar receptacles containing half hardy or tender plants, while contributing largely to the interest and adornment of the grounds, generally entails upon those responsible for their management a considerable amount of work and forethought.

The custom in many gardens of retaining certain subjects permanently in tubs throughout the year is commendable; instances such as Agapanthus umbellatus and Hydrangea Hortensia will occur to everyone conversant with this branch of garden management. These, however, take up considerable storage space in winter, and a change of occupants is desirable. The labour entailed in furnishing vases being considerable, care should be taken to employ plants of pronounced character in leaf or beauty of flower. Among the former, Musa Ensete, the Abyssinian Banana, is without a rival as a foliage plant; the bright-red colour which suffuses the underside of the midrib is a conspicuous feature of this plant, while the graceful form and unbroken outline of the leaves combine to make a plant of noble habit.

Plants can be raised from seeds sown in pots singly during March, and placed on a brisk bottom heat. Germination will probably take place within three weeks, and the seedlings may be shifted into larger pots as soon as the first leaf has fully developed. Employ rich soil, and afford the plants liberal shifts, loam and well-decayed manure in equal parts being used in the final potting.

In this locality we are generally able to place our plants in their summer quarters in the second week in June, but the selection of a suitable date must be governed by local conditions, which vary in different parts of the country.

Plants 6 to 7 feet high are quite common in the first year and where practicable, the old plants may be retained for use the second year by simply cutting away all the leaves, except those undeveloped in the centre. The plants may then be packed closely together in any cool orchard-house which is frost-proof. It need scarcely be remarked that a position sheltered from winds is of primary importance to this plant.

Cycas revoluta, which is annually imported to this country from Japan, as dormant stems, produces a quaint effect as a tub plant; the leaf colouring is a trifle heavy, yet, when skilfully employed as a foil to flowering subjects, the result is often pleasing.

Stock plants of Wigandia Vigieri and Solanum robustum which were raised from seeds in the previous autumn, if introduced to heat in January and pushed on, make vigorous specimens early in the summer. A pretty effect results by employing this Wigandia in the centre of a vase, and forming the ground and edges with Campanula isophylla alba.

Solanum robustum is densely clothed on the stem with a russet felt-like substance, while the leaf surface is more or less clothed with yellow spines; the stems also develop spines, though they are less prominent than those on the leaves.

FIG. 34.—SPECIMEN PLANTS ON THE TERRACE WALL AT WALMSGATE.

Rich soil and frequent supplies of manure water when in full growth are the salient features in the cultivation of Wigandia and Solanum.

Two good foliage plants for shaded positions are Fatsia japonica (Aralia Sieboldii) and Woodwardia radicans, a North American Fern, whose leaves arch gracefully from the stem, and often reach to the ground.

Flowering subjects.—During the past two seasons I have employed a single-flowering Pelargonium for furnishing a low terrace wall. It is called "Soldier's Tunic," a name singularly descriptive of the colour of the flowers. Cuttings are rooted in small pots during autumn; in spring these are placed in an early vinery, and as soon as the roots are active they are shifted into 6-inch pots, using a rich potting soil. As soon as the plants are well rooted into these pots they are placed in pots 9 inches in diameter, and finally into the vases, which are about 18 inches across by 15 inches deep.

Early in the season the main shoots are trained out flat, subsequent growth filling out the centre; all flower-buds are removed until June, and from July till October the vases appear like huge balls of orange scarlet. The individual trusses are always very large from this treatment, and the diameter of each plant is about 5 feet.

There is scarcely any plant which affords so pleasing a shade of lavender as Plumbago capensis; it is, however, liable to cause disappointment, unless it is thoroughly well rooted at the time of planting; used in conjunction with some of the large pink-flowered Verbenas, it affords a pleasing effect. Verbena "The King" produces a larger individual "truss" of a deeper shade of pink than Verbena "Ellen Willmott"; but the latter variety is much the best plant for "filling up."

Streptosolen Jamesonii, a useful greenhouse subject, also makes a successful vase plant; the colour, a bright orange-yellow, is not frequently seen, so that it offers a welcome change. The flowers are produced freely upon two-year-old plants, though, to ensure the maximum freedom of flowering, it is advisable to restrict the roots. There is scarcely any plant to rival well-grown specimens of Heliotrope President Garfield or H. Lord Roberts when cultivated in small vases placed in such positions that it is possible to look down upon them.

Erythrina crista-galli is usually a conspicuous feature in some of the London parks during autumn. The colour of the flowers is a brilliant scarlet-crimson, which, combined with their singular form, rarely fails to excite interest and admiration. It requires a long season to grow and liberal treatment to secure fine specimens. A moist atmosphere is essential when grown under glass, otherwise the plants readily fall victims to red spider. *T. S., Walmsgate Gardens, Louth, Lincolnshire.*

THE PROPAGATOR.

As the days lengthen, a commencement may be made in striking cuttings, seed sowing, and grafting, in the propagating house or hot-water pits. Beds of tree leaves and stable litter under ordinary garden frames are very successful under good management, but involve unremitting attention to ventilation in order to get rid of excess moisture arising from the fermentation of the materials of which the hotbed consists. A steady bottom and top heat must be maintained by means of linings of warm materials, of which a large mass should always be kept in readiness. Such hotbed frames are of great use in raising early Cucumber plants, and later on for starting the earliest Melons. In such frames cuttings of Solanums, such as robustum, pyracantha, and others employed in the flower garden; Wigandia caracasana, from shoots arising from the root-stocks, which have been started in a warmth of 55°; Ficus elastica, and others. Similarly cuttings of Lobelia erinus varieties, and Verbena hastened into growth, may have the ends of the stems cut off and inserted in pots filled with a compost of sandy loam three-quarters and leaf-mould one-quarter, surfaced with silver sand. The stock plants will furnish plenty of other cuttings if kept near the light in a warm house.

It is yet early to begin the general propagation of bedding plants, a fortnight hence being a more suitable time, before the general rise of the sap in the plants. There are, however, others of which seeds may be sown, as Pyrethrum aureum, Tagetes, Lobelias, and ornamental species of the Gourd family; Verbena venosa, and tender annuals, for flowering at an early part of the season. I may mention for early sowing, Cockscombs, Celosias in variety, Rodanthes, Acroclinium, Primula sinensis, Gloxinias, and Amaranthus.

Stove and tender shrubs.—Gardenias, Ixoras, Allamandas, Jasminums, and Cydonia japonica may now be grafted on a mild bottom heat, as also Camellias and Daphnes; also Roses

generally, on stocks specially potted up in the previous autumn, and consisting of Manetti or Rosa canina. Cuttings of such succulents as Echeveria, Pachyphytum, and Sempervivum may be inserted in sandy soil in well-drained pans, the soil being surfaced with sharp sand. A shelf in an intermediate house, where there is plenty of light, is the best place for them. Leaf cuttings of the following may be inserted this month and the next, viz., Echeveria, Aloe, Rochea falcata, Cotyledon, Bryophyllum, Peperomia, the herbaceous Begonias Thwaitsii, xanthina, Rex, splendida, and argentea. In the case of these plants the leaf should be removed from the plant close to the shoot or stem, leaving but little of the midrib. When the leaf is inserted in the soil of the cutting pot, a callus develops at the base, and later the roots and one or several shoots form at this point. It is essential that the leaves chosen should have reached a certain degree of maturity, those obtainable at about the middle of the plants, in order that they may be capable of withstanding the moist medium in which they will be placed, as well as of forming a new individual. If the grower wishes for a considerable number of plants, he can cut through the midrib on the under side and place the leaf flat on the soil. *F.*

VEGETABLES.

THE GARDEN SWEDE AS A WINTER VEGETABLE.

In some parts of the country the soil is not suitable for the white Turnip. In Scotland and the northern counties the ordinary white-fleshed Turnip, so common in the south, is by no means a favourite for winter supplies, or even at other seasons of the year; the yellow, or as they are often called the red Turnips, are more appreciated, and in some instances these are superior, as the flesh is less watery and the flavour is all that could be desired. My present note concerns the value of the Swede as a winter vegetable. There are two or three distinct varieties of garden Swede, and these are much hardier than the Turnip; indeed, the Swede grown for use in mid-winter may be kept good until the spring, and such roots must not be classed with the common Swede. They differ in growth and texture; they are not coarse; they have a very small top-growth, and the flesh is sweet and wholesome. The culture is very similar to that of the Turnip, and much depends upon soil and locality as to when the seeds need to be sown. We make two sowings in southern counties, one for raising roots for use from October to January, and another for furnishing a supply three months later. In many gardens where large quantities would not be required, one sowing would suffice. The roots may be wintered well in a clamp, or in a well-drained soil; they may be left in the open and used as required. From sowings made in August or September, good roots may be obtained that will winter well if not of too large a size. As regards varieties last season, I had a very fine variety on trial which stood the severe weather in January perfectly well in the open in the south. This was Crimson Top Table Swede, a variety with orange-coloured flesh, and one that is remarkably hardy, making a splendid winter vegetable. There is also a small white garden Swede much the same as the yellow one in growth and hardiness, but it is a pure white; I do not think the flavour quite equal to that of Crimson Top. Where the yellow flesh is not appreciated the white variety may be grown, and there will be no lack of good roots all through the winter months, and at a period of the year when good garden Turnips are not to be obtained. Roots for consumption in winter should not be cultivated on recently manured land, as they would grow less solid and therefore be incapable of keeping well. *G. Wythes.*

FRUIT REGISTER.

PEARS IN JANUARY.

Winter Nelis is a Pear of medium size and one of the finest late Pears. The fruits should be left on the trees until they will readily leave the spurs, and the gathering should be carefully done, laying each fruit on wood wool, so that no bruising will take place. This variety requires a warm position to grow in, and the fruits need to be thinned.

Easter Beurré is much larger than Winter Nelis when well grown, and needs to be extra well grown to bring out its best qualities. The fruits are very appreciable in January. This Pear, if grown on light soil and against a wall, requires a lot of water, and the fruits should be thinned rather severely.

Glou Morceau is good at Christmas time and for a week or two afterwards, provided the fruits have been thoroughly matured before gathering. It is large. The trees should be planted against a south-west wall to bring the fruits to perfection, when they are buttery and very delicious.

Nouvelle Fulvie, at its best during January, has a refreshing flavour when the fruits are well developed. This variety bears fairly well, and should be thinned early.

N. Plus Meuris. The fruits of this variety are small to medium size, and in use from January to April, according to the condition it has attained. Pears of this class should be brought on artificially as occasion demands for consumption.

Olivier de Serres.—This is a very sweet fruit, and an excellent cooker, with a skin covered in russet-brown. The variety is a prolific bearer and hardy; it should be always included in a collection of late Pears. The fruits will keep in good condition until February and March, but may be used in January.

Joséphine de Malines. This is a very fine Pear when well matured, but unless it is thoroughly ripe it is not good. At its best it is rich and delicious. The fruits are in season in January and February, and can be hastened in January quite easily if placed in a warm atmosphere. The trees require a rather warm position.

Triomphe de Jodoigne is a large and handsome fruit in season at Christmas.

Bergamotte Esperen. This variety is a finely flavoured fruit when well developed and grown in a warm position; it needs to be severely thinned.

Le Lectier.—A fine large Pear, highly perfumed, and very juicy. It is a good bearer, and is quite the Doyenné of its season, which extends from January to March. The fruits need to be thinned with extra severity.

Marie Benoist. The fruits of this variety are large, but not always of the best flavour. It varies considerably, in some places being very good. It is a good late variety and always useful for cooking. The tree succeeds well as a cordon, pyramid, or a fan-trained tree. The fruits are in season from December to February.

Passe Colmar.—This fine late Pear has a very rich, pungent flavour, but on some soils is inclined to be gritty; I believe this condition is solely caused by dryness at the roots. This variety is good in March, and I have kept it in good condition until April.

Prince Eticard is a roundish fruit and a valuable late Pear, being of good flavour. The tree is a prolific bearer, and the fruits are in season in January.

Beurré de Naghin.—A modern variety, and illustrated in *Gardeners' Chronicle*, December 28, 1907. I have not found this Pear in season so early as at Christmas yet, but it will keep till March very well, and must be extra well ripened to be at its best. It cooks splendidly.

Chaumontel.—A large, richly-flavoured variety when well developed, otherwise not much good. It requires a warm position, when it is an admirable Pear, most agreeably perfumed. This Pear is grown very extensively in the Channel Islands, where it is superb.

Bellissime d'Hiver is a fine Pear for cooking purposes, and succeeds well as a pyramid on the Quince stock, being, moreover, very hardy.

Duchesse de Bordeaux is a fair size when well grown, has a russety appearance, and a rich Beurré flavour. It succeeds well when grown as cordons, and is in season from the end of January until March.

Beurré Rance is one of the best late Pears, and has a refreshing flavour. It is a variety that should be well grown, and needs to be lifted or root-pruned occasionally, and should be cultivated against a south-west wall.

Doyenné d'Alençon is a fine January Pear; one that requires a good wall, high-class treatment, and severe thinning of its fruit.

Catillac.—This Pear is about the best for stewing purposes, and may be kept easily until April; it does well whether trained as a cordon, pyramid, fan, or horizontal espalier. Naturally, the best fruits are those obtained from wall trees, although I have seen heavy fruits from large standard trees, and in a warm autumn, when they are allowed to hang to thoroughly ripen, they are excellent.

Hardy's Prince of Wales.—This is a very fine Pear of great merit and of a nice size for dessert purposes. It bears well on the Quince stock and on quite young trees.

Knight's Monarch.—I have kept this Pear in good condition until March, and it had still a good flavour. The trees sometimes drop their fruits, but for all that they should be thinned severely, because the fruits are produced in large clusters.

Duchesse de Mouchy is a good late cooking Pear and a fine keeper. *H. A. Cook, Leonardslee gardens, Horsham.*

APPLE COX'S ORANGE PIPPIN.

The best Apples to plant are often discussed at this season of the year, and Cox's Orange Pippin is always mentioned in the first three. Although fruit of this variety usually commands prices twice as high as other varieties, the trees are sometimes alleged to be rather shy. I would point out Cox's Orange Pippin should always be planted with other varieties of Apples near at hand, in order that the pollen of the blossom may be crossed and in this way the fruits set much more freely. A good plan is to plant Cox's Orange Pippin intermediately with another sort. In this way there is a good chance of the trees cropping freely. *Free Lance.*

FOREIGN CORRESPONDENCE.

HISTORY OF PHILODENDRON CORSINIANUM.

I read on p. 25 of the *Gardeners' Chronicle* for January 11 a reference to the description of × Philodendron Corsinianum in the *Botanical Magazine*. Briefly, the history of this plant is as follows. × Philodendron Corsinianum belongs to a very interesting series of hybrids raised more than 20 years ago in the public gardens of "Le Cascine," in Florence, by the foreman, Mr. Ferdinando Ragionieri (now head gardener to H.E. the Prince of Venosa, at Albano, near Rome), and the Director, Cav. A. Pucci. The beautiful Lælio-Cattleyas Arnoldiana and Ridolfiana, sent out by Messrs. Sander & Sons, some good Cypripediums, Alocasia pucciana, distributed by Mr. Godefroy Lebœuf, A. Luciani, distributed in Belgium, some Bromeliads, many fine Calaniums, &c., were among the hybrids raised there. × Philodendron Corsinianum is a cross between P. Lindenii ♂ and P. lucidum ♀. It was dedicated to H.E. the Prince Corsini, then Mayor of Florence. The entire stock of the plant was purchased by Messrs. Makoy, of Liege. *Dr. A. Ragionieri, Castello, near Florence, Italy.*

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Cypripediums.—Probably no other large genus of Orchids contains so few kinds that are difficult of cultivation. There is hardly a species or hybrid of Cypripedium but will thrive well if cultivated in a suitable degree of heat. Moreover, fogs are not so destructive to the flowers of Cypripediums as they are to many other Orchids which bloom at the same time. The species C. insigne, of which there are many fine varieties; C. Charlesworthii, C. Fairrieanum, C. Spicerianum, C. villosum, C. Boxallii, and their hybrids C. Leeanum, C. Euryades, C. nitens, C. Prospero, C. Niobe, C. Arthurianum, C. Actæus, C. Calypso, C. Lathamianum, C. Hitchinsiæ, and many others are all desirable kinds that flower during the winter season. This section is best accommodated in a cool, intermediate temperature at all times, as when grown in a hot, moist atmosphere, flowers of the best quality are rarely produced. It is not absolutely necessary to have a special house for the cultivation of these Orchids, as they may be grown with a fair amount of success in an ordinary greenhouse, where the heat in winter does not fall below 45°, provided great care be paid to watering and damping in winter, and that requisite shade is given in summer.

Potting the plants.—Whilst some plants of Cypripedium are still making a display, there are many that have ceased to flower. These should be examined to ascertain if re-potting is needed, and those plants that require fresh rooting material should be given attention forthwith. If large specimens are required, root-bound plants should be given a liberal shift, as the majority make roots freely. Copious supplies of water being needed when the pots are filled with roots, perfect drainage must be provided, and this should be covered with a layer of sphagnum-moss or loam fibre to keep it from becoming choked with the finer soil. When potting Cypripediums, the crown of the plant should be kept rather lower than the rim of the pot, and the compost made moderately firm about the roots. The compost should consist of good fibrous loam one-third, turfy peat one-third, and one-third leaf-soil and sphagnum-moss in equal parts, with a good sprinkling of coarse silver sand and small crocks, mixing the whole well together. If the mixture when used is in a fairly moist condition, no water will be required after the operation for some days; then a thorough soaking should be given.

Seedlings.—Where the raising of these plants from seed is practised, there will be small seedlings at this season in need of pricking off. If this operation is done forthwith, it will enable the little plants to get hold of the compost before the summer arrives. Seedlings standing singly in small pots, if well rooted, may be afforded a slight shift. The compost employed during the early stages should consist of equal parts peat, leaf-soil, and chopped sphagnum-moss. When the plants are moved into pots 3 inches in diameter, a small quantity of loam may be added to the compost, increasing the quantity to one-third when they are nearing the flowering size.

Sowing the seed.—Seed which has ripened and been gathered during the winter may now be sown. The surface of newly-potted plants make the best seed-beds, and these should be given a thorough soaking of water a day or so prior to sowing. Afterwards, afford water carefully till such time as the seed gets embedded in the compost, making use of a fine rose watering can to keep the surface moist. Occasionally the pots may be dipped in a vessel of water to half their depth, which will moisten the compost at the bottom of the pot.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

The rust of Chrysanthemums.—This pest should be dealt with in a very drastic manner, as nothing that I know of will kill it in the way of an insecticide or solution without destroying or damaging the plant also. With a little trouble at this time of year any infected collection can be cleaned. The best and simplest way to deal with it is to take one of Wolff's garden pencil protectors and after sharpening the small end of the protector, use this as a puncher on the infected part of the leaf. The man in charge of the collection of plants will soon get to know the rust in the leaf before it comes out into a powdery form, by holding the leaf up to the light and looking through, or using a magnifying glass until he gets used to the appearance of it on the underside of the leaf. When discovered take the leaf in one hand and the puncher in the other, and simply press over the spot of rust, cutting it clean out. Care should be taken to commit all the bits to the flames, this being the only method for destroying the pest. At this date the plants or cuttings are small, and there are not many leaves to look over. The rust should never be allowed to burst its spore cases and propagate itself. As near as I can tell, it takes about six weeks from the time a spot bursts and the spores are deposited on the under side of the leaf until it shows itself again and is ready for distribution. If this mode of destruction is strictly attended to, there will not be a spot on the plants by the time they are in 6-inch pots. The plants should be looked over twice a week at the start when rust appears, and at a certain stage it comes up in a day when in a close, humid atmosphere. I have practised this treatment ever since the rust came to this country, and have always kept clear, although each season some is introduced here on newly-purchased plants, these are always kept by themselves and examined for about two months until pronounced clean. Should rust be found on newly-purchased plants in a garden near to a large town, there is less need to trouble about it, as it will not propagate so readily there, the atmosphere being impregnated too much with sulphurous fumes to favour the growth of the rust when the plants are placed out-of-doors.

Violets in frames should be examined for any damped leaves or flowers, and these very carefully removed, for at this time of year the leaves are very crisp and may easily be broken, and, if so, are certain to damp off. Flowers are showing freely now, and plenty of fresh air should be admitted to the plants on every favourable occasion as long as the temperature is above 32°. If frost and rain be kept out of the frames, exposure to all the sunshine that is possible is all that is required.

Clivias.—The earliest will now be showing signs of flowering, and should be placed in a warmer atmosphere, and where they will obtain plenty of light; as the plants grow in leaf simultaneously with the flower, a liberal supply of nutriment should be afforded in a liquid form; and as soon as the flowers begin to expand, the plants should be removed to a cooler house. By using the same plants for forcing every year and in the same rotation, it becomes almost the plant's natural habit to start away readily into bloom in the spring.

THE HARDY FRUIT GARDEN.

By E. BOWMAN, Gardener to The Dowager Lady NEWTON-BUTLER, Warter Priory, Yorkshire.

Insect pests. After the pruning and training of the trees are completed, every fruit-grower whose ambition it is to have healthy trees and fine fruit will take the opportunity now offered him to destroy all insect pests, or, at any rate, to use such efforts as are possible to keep them in check, carefully raking up all prunings, and removing the surface soil from badly-affected trees and conveying them to the smoulder heap. American blight is the worst pest that attacks Apple trees, and it is one of the most difficult to eradicate. Where Apple trees are badly affected, only those who pay close attention to them during the season of growth and spray them during the winter can hope to have them in a clean and healthy state. Mussel scale is another most persistent pest, which not only attacks the bark and rind of the stems and shoots of the trees, but the fruit as well, if measures are not taken to destroy the insect. The caustic soda solution, so many times recommended in the Calendars of the *Gardeners' Chronicle* for animal and vegetable parasites, is still the only safe and effective remedy to use by those who make their own wash. There are, however, so many cheap preparations now obtainable which are of use in destroying insect pests that it is scarcely necessary to go to the trouble of making one's own. The cheapest and one of the best sprays for large or small orchards that I have used is V.1 Fluid for winter spraying and V.2 for summer spraying, both of which are safe and effective against all garden pests. The best manner of applying these and other sprays to large trees is by means of Vermorel's knapsack sprayer; and for small gardens a hand syringe with a spraying nozzle does equally well. Care should always be taken to choose a mild day for carrying out the work, to put on an old suit of clothes, and wear leather gloves.

Pear midge.—This is a most serious pest to deal with, and is very prevalent in the Midlands and South of England, more so, indeed, than in the North. Williams' Bon Chretien and Doyenné du Comice are varieties that seem to suffer more than any others. It is very difficult to suggest any remedy, but by collecting all Pears that fall to the ground, pulling all deformed fruits from the trees, and removing the surface soil at this season, conveying both to the smoulder fire, something may be done to fight the pest. In addition, fresh soil should be substituted for that taken away, and the addition of 1 lb. of kainit to the square yard, ½ lb. in the autumn and ½ lb. in the spring, repeating the operation the following season, will improve the results. The surface soil cannot be removed from areas of orchards under grass, but the swollen Pears can be picked up and burnt, and kainit applied with good effects.

Loganberry.—This is a useful addition to our list of hardy fruits, and should find a place in every garden. Although not quite a novelty, the fruit is not so well known as it deserves to be. The plant is of vigorous growth, therefore it should be planted at from 6 to 8 feet apart. Treated similarly to the Raspberry, the Loganberry fruits freely, and it does well in many gardens where the former is not a success. The plant may be grown on rough fences, walls having a north aspect, or on pillars as single specimens. After fruiting, the older canes should be cut away, and the stronger of the young ones laid-in thinly. The fruit ripens during July and August.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Cherries and Plums.—Established trees of these fruits growing in pots, plunged in a bed of coal ashes outdoors, should, if it be desired to advance the ripening season of the fruit, be now placed in a light and adequately ventilated glass-house. In arranging the trees ample space should be afforded so as to let plenty of light and air reach them. Cherries and Plums, especially during the early stages of growth, are very readily injured by high temperatures due to artificial means; and until the trees come into blossom the temperature should not exceed 45° Fahr., and the house should be ventilated by day and night, whenever the weather will permit of this being done, so as to ensure a gentle movement of the air of the house. The trees, just previously to the blossoms expanding, should be fumigated, and when the flowers have expanded, a moderate degree of artificial warmth must be afforded and maintained, together with a tolerably free ventilation, so that a damp, sluggish state of the air may be avoided and the setting of flowers accelerated. Excepting during flowering, the syringe may be made use of in the morning if the day promises to be fine. A moderately moist atmosphere may also be maintained. Cordons and other forms of trees should be similarly treated to the pot trees, and great care in every case should be taken in applying water during the early stages of growth.

The making of a vine border.—The winter is a suitable season for the formation of a border which is to be planted in the spring. Many are the ways recommended for doing this, and success is obtained by widely different methods. Some cultivators place the vine border wholly outside the vinery, others entirely inside, while others place it inside and outside. When properly made and managed, and the surrounding conditions are suitable, a border may be quite satisfactory whatever the form. A border may

be made about 4 feet in depth, and it may be provided with a properly constructed concrete bed, if the soil be clayey or otherwise of an unsuitable nature; and it should be adequately tile-drained with 1 foot of carefully arranged brick or stone rubble placed over the entire bottom of the border, so as to readily drain the soil and prevent the lodgment of water. Having done this, there will be space for 3 feet of compost, is not too deep if drainage is good. It is always desirable to make a border in sections of about 4 feet in breadth, adding to the front as the roots are found to require further space, until the full breadth is reached. Where provision is made for an external and internal border, it is better to plant the vines in the inside one, and let their roots permeate it throughout before making a border outside the vinery. Good turfy loam, if possible off limestone or chalky formations, should constitute the chief proportion of the compost used; and to this, after it has been roughly broken, there should be added, according to its texture, more or less crushed mortar rubble, wood ashes (from greenwood), and finely broken bones. Other fertilisers, the effects of which are of comparatively short duration, are sometimes employed; but these can be more economically and beneficially applied after the vines have become established and are in need of assistance to bring their fruit to perfection. The chief requirement at the first is abundance of healthy roots, ready to absorb nutriment when it is mostly wanted. The materials when put together should be in a fairly dry state, and be made firm during the progress of the work.

Vines for planting.—These should be kept in a late vinery, and water applied to them with caution, so as not to cause the bursting of the buds before they can be planted, directions for which will be given in due course.

PUBLIC PARKS AND GARDENS.

By JAMES WHITTON, Superintendent of the Parks and Open Spaces in the City of Glasgow.

A concrete example.—In regard to my remarks last week as to the necessity for looking ahead, let me emphasise this by a concrete example. Few of our large cities have escaped the evils created by the shortsightedness of the governing authorities of past generations in respect to their neglect in the reservation of open spaces, and the city which I have the honour to serve has suffered probably as much as any other. This city, however, in recognising the evils of overcrowding, has adopted and continues to pursue the policy of "looking ahead," and it may be of interest to many readers if I attempt to outline the progress made. Prior to the middle of last century the city had only one large open space, which to all intents and purposes was a common, though from its proximity to the river Clyde it was the favourite place for the bleaching of the household linen of the citizens, and came to be designated "The Green," which name it yet bears. It was also the favourite rendezvous of the people, and much of the civic history is interwoven with the old park. The great expansion of the city which began in the early part of last century with the tendency westwards—and seawards—with the consequent disappearance of the green fields and woods which adorned the suburbs, caused serious concern in the minds of thoughtful citizens as to the necessity of preserving some of the "beauty spots" from destruction. To think was to act, and the result was the purchase of a notable place, which was then out of the city boundary. With the wants of the western section of the city supplied, the civic authorities next turned their attention southwards, as the city was rapidly extending in that direction, and another place outside the municipal boundary was secured. As indicating the feeling which arose through the action of the awakened spirit in the corporation, when the matter was discussed in council, the vote was even and the decision to purchase was only carried by the casting vote of the Lord Provost. Everyone now agrees that if ever a chairman deserved honour for the exercise of wisdom and courage at a critical moment, when so great a principle was involved, it was on that occasion. The purchase in question was laid out as a park and managed by the corporation for over thirty years before it was included within the city area, and has been referred to by many other municipalities, when engaged in discussing similar schemes, as an outstanding example of looking ahead to meet future requirements in the development of an expanding city. A few years later, another space was secured for the north-eastern district, and so important had this factor become in city life that when the last great extension of the municipal area was under consideration by the authorities, most of the suburban burghs affected made it one of the conditions of amalgamation that their respective districts were to be provided with a park within a given time after annexation. Thus with the increase of the city within the past generation, the parks have increased fourfold and the smaller places to a greater extent. Some of the areas were secured at very reasonable prices, the owners appreciating the policy of the council in regard to the welfare of the health and vigour of the rising population, as well as to the improvement of the amenities of the city. Several had to be paid for at very high prices, while others were given by public-spirited citizens. The last park presented, though six miles from the centre of the city, is a place of much natural beauty, and so well served by the municipal tramways that it has become a favourite resort, and on holidays and Sundays when the weather is fine the number of visitors who enter the gates is frequently estimated to exceed twenty thousand. To those interested in parks, it is very gratifying to note that the appreciation of these places by the public is causing some of our generous-minded countrymen to make their gifts for the benefit of those less fortunate in life than themselves, take this form.

THE KITCHEN GARDEN.

By L. BUCKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Digging and trenching.—This important work should be pushed forward as quickly as possible so that the soil brought up from the bottom may receive all the benefit possible from the winds and frost which may occur between now and the time for seed-sowing and planting. In very wet weather, especially on heavy land, it is not advisable to attempt this work when the ground is in a soddened condition, but full advantage should be taken of all dry weather.

Trenches for crops.—Good trenches for such vegetables as Peas, Runner Beans, Leeks, and Celery should now be taken out. Throw out the soil on either side, wheel in and fill up the trench with manure, and leave it exposed to the atmospheric influences.

Pea and Bean sticks.—A good stock of these should now be got together and stored in their respective sizes, and during wet days they may be got under cover and trimmed and sharpened ready for use.

Onions.—Those raised from seeds sown in boxes at the beginning of the year will need pricking out into other boxes, placing the plants at distances of 3 inches all ways. Use a compost consisting of three parts fibrous loam, one part manure from an old Mushroom bed, one part well-decayed leaf-soil, adding a dash of bonemeal and sufficient road grit to ensure it being quite porous. It should be used in a moderately dry condition and be made very firm. Place the boxes in an atmospheric temperature of from 50° to 55°, and expose the young plants to the full light. Frequent light syringings with tepid water will be beneficial to them.

Leeks should be treated similarly to the Onions except that no bone-meal should be added to the compost, and the plants must be inserted much deeper in the soil than Onions. Afford them the same degree of heat.

Parsley is in demand the whole year through, both for garnishing and flavouring various dishes. Consequently seeds should be sown both early and late in the season. The most successful manner of producing a good supply all through the summer is to sow seeds in a box at this season, raise them in a gentle heat, and plant out the seedlings on well-prepared ground early in April at a distance of 12 inches apart all ways. A well-grown bed of Parsley of a good variety is a most refreshing and pleasing addition to a kitchen garden. Late sowings which were pricked off in cold frames should have the lights entirely removed when the atmospheric temperature out of doors reaches 40°. Remove any decaying leaves from the plants, and dust the plants over with soot. Stir the surface soil.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Propagating house.—It is well at this season to have, in addition to hot-water pipes, a good hotbed for the propagation of such plants as Lobelia, Heliotropium, Verbena, Ageratum, Iresine, Fuchsia, &c. Sow seeds of Begonias, Salvias, &c., in pots or pans, and cover the pans with pieces of glass until the seedlings appear. For raising plants suitable for subtropical bedding, sow seeds of Daturas, Giant Hemp, Eucalyptus, Chamæpeuce, Centaurea candidissima, Grevillea robusta, Acacia lophantha, and Hollyhocks.

Calceolarias.—Give attention to the shrubby kinds used for bedding, which are generally wintered in cold frames, such as Golden Gem, General Havelock, Victoria, Burbidgii, and amplexicaulis. Stop the plants at about the fourth leaf, with the exception of those intended for forming standards, *C. amplexicaulis* being the best for this purpose. Our plants of this species intended for that purpose are now in 4-inch pots, and are about 2 feet in height. When they attain 4 feet we shall stop the plants, so as to induce them to form heads, and afterwards repeatedly stop them as growth continues, until the plants are placed out of doors. This species, when grown in this manner, with its clusters of soft lemon-yellow flowers, is much appreciated when bold groups or masses are formed; the plants prefer a good loamy soil. Standards of Iresine, of which *I. Lindenii* and *I. Herbstii* may be considered the best, should be cultivated on single stems to the desired height, and treated in the same manner as advised for Calceolarias. We cultivate white and yellow Marguerites upon the same principle.

The planting of shrubs.—Autumn may be the most favoured time for planting, but when the ground has been well prepared and exposed to frost, planting may with equal success be carried out in the month of February. Of suitable plants as single specimens, or as groups to afford pleasing effects at all seasons, there are noticeable at the present season *Cryptomeria japonica*, whose foliage is browny-crimson in tint; Golden Privet, a good companion plant, when the variety is true; Common Lavender, with its hoary grey foliage and at all times acceptable fragrance; Arbutus Unedo, the so-called Strawberry tree, which was unfavourably affected by the weather last season, few fruits having set, but the smooth, shining green leaves are always attractive; Phillyrea is an evergreen of much beauty; Buxus sempervirens variegata pendula, as a single specimen, is at the present a very conspicuous shrub; Laurustinus was flowering at Christmas, and will be so at Easter; Cytisus Andreana, the wood and twigs of which are of a beautiful green tint, with flowers of yellow and crimson that come in the early summer months; and, lastly, Spanish Broom, with its round, slender, green, twiggy branches, whose flowers last from June to September. A good effect is produced when the winter-flowering Jasminum nudiflorum is planted in the shrubberies, and the growths are fastened to Larch stakes, &c. Buddleia variabilis Veitchii is a conspicuous plant during the winter, by reason of the grey felted stems and leaves, and from June to September on account of its pyramidal terminal clusters of blooms, some of which measure 2 feet in length. The flowers are fragrant and of a lilac colour. Sea Buckthorn (Hippophae rhamnoides), so showy with its bright orange berries in the winter, and the silvery-grey foliage in the summer, will grow in almost any soil, and is a most picturesque shrub in the shrubbery or on the lawn.

Dahlias.—Firefly, Victoria, and others of the Cardinalis type, when planted with good taste, are amongst the most ornamental of flower garden plants. Our plants were lifted in the autumn and stored in boxes with leaf-soil and sand around the roots and put away in a dry, unheated greenhouse. They are now being removed bodily to slightly warmer quarters to be divided into pieces when the fresh roots become visible. These will be placed in small 48's in a compost consisting of leafmould, sand, and loam, in an atmospheric temperature of about 55°. When well established they will be removed to cold frames. Seeds of Dahlias may now be sown in heat.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Appointments for February.

THURSDAY, FEBRUARY 6—Linnean Soc. meet.

TUESDAY, FEBRUARY 11—
Roy. Hort. Soc. Comm. meet. and Annual Meet. of Fellows. Annual Dinner of Hort. Club. British Gardeners' Assoc. Ex. Council meet.

FRIDAY, FEBRUARY 14—
Roy. Gardeners' Orphan Fund Annual Meet. and Elect. of Candidates.

THURSDAY, FEBRUARY 20 Linnean Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich=38°4.

ACTUAL TEMPERATURES:—
LONDON: *Wednesday, January 29* (6 P.M.): Max. 43°; Min. 37°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London. *Thursday, January 30* (10 A.M.): Bar. 30·1; Temp. 41°; *Weather*—Fair.

PROVINCES.—*Wednesday, January 29* (6 P.M.): Max. 40° Guildford; Min. 35° North-East coast of Scotland.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—
Sale of Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY AND FRIDAY—
Herbaceous Plants, Liliums, Begonias, Gladiolus, Ferns, &c., at 12; Rose Trees at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—
Border plants and perennials, Lilies, Begonias, and other bulbs at 12; Roses and Fruit Trees at 1.30; Azaleas, Rhododendrons, Palms, &c., at 5, 1,021 cases Liliums from Japan at 1; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—
A collection of rare and curious Orchids; Orchids in flower and bud; at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

The Gardeners' Benevolent.

The brief report of the annual meeting of the Gardeners' Royal Benevolent Institution that we were able to insert in our last issue affords a correct indication of the present condition of the premier gardening charity. The information is gratifying in the sense that it shows what a great amount of excellent work is being done by generous-minded supporters towards relieving the absolute necessities of aged gardeners and their widows, in many cases saving them from the indignities of parish relief or even the workhouse. In view of what has been accomplished in this matter and the disinterested efforts that are being made by the Executive Committee and officers, it would be ungrateful not to record the general result with appreciation. The Committee is composed of gentlemen whose names command the highest respect amongst horticulturists, and when they decided that the funds of the Institution warranted them in advising the election of eighteen additional pensioners, they undoubtedly recommended the highest number possible under the circumstances. Owing to a recent death, one more was added at the last moment, making the number nineteen, and after the election, and in exercising the power invested in the Committee by Rule III., Clause 10, two of the unsuccessful candidates, who had sought election on five occasions, were added to the roll, making the number twenty-one. Still further additions were made possible by the liberality of Mr. Arthur W. Sutton and Mr. George Monro, each of whom promised to provide a year's pension for one candidate. The candidate receiving Mr. Sutton's gift was a gardener who is totally incapacitated by disease at the age of forty-three, and for Mr. Monro's gift a destitute widow was found, aged 82 years, whose husband had been a gardener all his life, but had never held a position that enabled him to make any provision for old age or for his widow. Thus there were twenty-three new pensioners placed on the funds.

So far so good, but when we consider the proportion of those elected with the total number of deserving applicants, we feel obliged to appeal to our readers for additional support. Twenty-nine sought election and failed, including one, at least, whose case has been before the subscribers five times. Is not this fact in itself ample justification for the importunity of the Committee in their endeavours to obtain new subscribers, and should it not be the means of awakening those who have not previously associated themselves actively with this movement, to bestir themselves and assist in the beneficent work for which the Institution exists? The only satisfaction in the circumstances is the knowledge that the candidates who suffered disappointment at the recent election will receive from the Institution some help at least during the year that will elapse before they can again seek election.

It may be pointed out that a gardener or his widow is not eligible for election who has not attained the age of sixty years, unless the candidate is totally incapacitated by accident or incurable disease. Every care is taken by the Committee to investigate each case presented to them, and only such are recommended for election to the subscribers as conform perfectly to the rules, and are actually in need of relief. It cannot, therefore, be held that the list of candidates is swelled by the addition of cases that might be allowed to wait without causing the candidates to suffer serious privation. The sole reason for rejecting any of them is that the income from all sources is insufficient to meet the increased amount of financial liability that their election would place upon the Institution. Considering for a moment the principal sources of income, these may be said to be three, and include contributions from members of the horticultural trade, from gardeners, and from the general public, the general public in this sense being represented by proprietors of gardening establishments. The horticultural trade has nobly responded to the claims of the Institution in the past, and we feel sure that, as a body, it will continue to do so; it is evident that more money is now required than heretofore, and if any representatives of the trade can afford to increase their donations and subscriptions, or if the suggestion made by Mr. Arthur Sutton at the general meeting that all the firms may possibly see their way to increase the support they have already given the Institution, Mr. Harry J. Veitch and his Committee will be the more encouraged in the carrying out of their arduous work.

The amount contributed by professional gardeners might be increased if all gardeners could be sufficiently convinced of the value of the help the Institution affords and the pressing need that exists for larger funds. It is not meant that those who now contribute should give an increased amount, but rather that those who are not at present on the books at all should commence to subscribe one guinea a year. This contribution represents rather less than three farthings a day, and many gardeners could possibly afford this if they made up their minds that the necessities of the case demand it. But an appeal can also be made to gardeners on business grounds. If they should ever need the help of the Benevolent Institution themselves, they will receive one hundred preference votes at the election for every guinea previously subscribed to the funds, and those who subscribe for twelve or more years will be practically certain that their case will be successful. We feel, therefore, that, notwithstanding the inadequate remuneration gardeners in general receive for the skilled services they render their employer, an appeal may conscientiously be made to them to help as far as their means will allow.

The general public at present contribute a large share of the income, and their donations are obtained in great measure in connection with the annual festival dinner. The proprietors of gardens might be induced to help still further if their gardeners would, in a larger number of instances, lay the claims of the Institution before them. But in this connection it is probably true that the gardener who would succeed in enrolling his employer among the annual subscribers must first become a subscriber himself, because help is always more readily afforded those who show that they are themselves doing what lies in their power to provide for future needs.

Another source of income is that of legacies, the Institution having gained more than £3,500 in this manner. Those who have the opportunity of advising others in the matter of making provision for the future disposal of their estates should try and induce them to include the Gardeners' Royal Benevolent Institution in the list of legatees. A few supporters of the Institution make it a practice to throw open their grounds to the public at certain seasons of the year, and the small sums paid for admittance on such occasions are handed over to the charity; some use their influence in obtaining collections at horticultural exhibitions, or in the organising of concerts for the same purpose, and it is more than probable that others could afford help in one way or another, and thus contribute to increase the total income.

In addition to the general fund, which is mainly employed for the provision of pensions of £20 per year for a male or £16 a year for a female, there are the Victorian Era and Samaritan funds, which claim the attention of the charitable. The Victorian Era Fund is used for the granting of temporary aid to those unsuccessful candidates who are awaiting election and who were at some period subscribers to the Institution, whilst the Samaritan Fund is available for giving help to those who alike await election but who were never subscribers. Both funds are valuable, but the claims of the Samaritan Fund are irresistible. It is the only fund that enables the Committee to make a grant of money in cases of acute distress where

temporary assistance is most called for. We have read letters from the friends of the recipients of such help, and feel that if it were possible to print them they would move even the most indifferent to a sense of their responsibilities in regard to the exercise of benevolence.

In view of the many good friends the Institution has lost during the past year through death, it is a source of satisfaction to find that young men continue to come forward to fill the vacancies thus caused. Mr. Martin H. F. Sutton, who presided at the friendly supper at the conclusion of the annual meeting, showed by his presence and speech that in future years he will be amongst those who will do their utmost to help in mitigating the sufferings of those who are unable to meet their own necessities.

It may be stated here that the next annual Festival Dinner will take place on June 24 at the Hôtel Métropole, when Lord Aldenham will preside. We hope all will unite to make the event as successful as possible, and those who are willing to act as stewards on that occasion should send an intimation to this effect to Mr. George J. Ingram, the secretary.

OUR SUPPLEMENTARY ILLUSTRATION.—Of the numerous and remarkable members of the genus Hæmanthus, H. Katherinæ, Baker, the subject of the accompanying illustration, stands out far in advance of all the rest not only in regard to the beauty of its flowers and foliage, but also the ease with which it may be cultivated in an ordinary greenhouse. It was first described in the pages of this journal in 1877, p. 656, by Mr. BAKER, who named it in compliment to Mrs. KATHERINE SAUNDERSON, wife of the gentleman who first sent dried specimens, which he had collected in Natal, to be determined at Kew. Living plants were introduced shortly after by Mr. KEIT, of the Natal Botanical Gardens, and a figure appeared some years later in the *Bot. Mag.*, t. 6778. Unlike most of the members of the genus, this species is practically evergreen, as the new set of leaves, which appear contemporaneously with the flowers during spring and early summer, commence to push up before the fall of those of the previous year, bursting through near the base of the old leaves and reaching a height, when vigorous, of from 2 to 2½ feet. The leaves are from four to eight in number, elliptic-lanceolate, 12 to 18 inches long, 3 to 6 inches broad, light green in colour, their sheathing bases forming an erect stem-like structure surmounted by the spreading leaves. The flowers are borne in densely-flowered globose umbels—that of the plant figured being 10 inches in diameter—on stout, erect peduncles, which usually rise a little above the foliage. The perianth is bright scarlet, spreading, 1½ to 2 inches in diameter; segments lanceolate, slightly reflexed with age. Filaments erect, bright scarlet, 1½ to 2 inches long; anthers, pale yellow; stigma equal or slightly exceeding the stamens. The long stamens give the whole inflorescence a most beautiful feathery effect, beneath which is the dense mass of the spreading scarlet flowers. H. Katherinæ is closely allied to, and often confused with, the tropical African H. multiflorus, also the West Tropical African H. cinnabarinus, both of which species are deciduous, require tropical conditions, and may be readily distinguished from the first-named by the fact that in H. Katherinæ the inflorescences are borne on separate and distinct peduncles, lateral to the leaves, while in both of the tropical species the inflorescences spring direct from the centre of the leaves.

R.H.S. GUILD.—In regard to the proposal to form a Guild of R.H.S. students, as mentioned in our last issue, we are asked to state that a meeting for this purpose will be held in the lecture room at the Vincent Square Hall on February 11, at the conclusion of the annual general meeting of the Royal Horticultural Society.

NATIONAL CHRYSANTHEMUM SOCIETY.—The annual general meeting of the members of this society will be held at Essex Hall, Essex Street, Strand, on Monday next, February 3, at seven o'clock in the evening. The president, Mr CHARLES E. SHEA, will preside. In addition to the ordinary business the meeting will be asked to consider, and if approved to adopt, the following resolution, viz: "That in rule 16 the words 'No member of any committee shall be eligible for nomination as a judge at any of the society's exhibitions' be deleted, and that the word 'Honorary' be inserted at the beginning of the rule." The new rule will then read as follows: "Honorary judges at the various exhibitions shall be appointed by the executive committee. The votes shall be taken by means of voting papers."

HORTICULTURAL CLUB. The annual dinner of the club will be held on Tuesday, February 11, at 6 p.m., at the Hotel Windsor. Ladies are specially invited to attend this function. The annual meeting will take place at 5 p.m.

THE KEW BULLETIN (1908, No. 1) contains an interesting account of the fruit fly, which has proved a troublesome pest in the Orange plantations of Australia and elsewhere. It is the same insect, Ceratitis capitata, which is known in Malta. Various remedies are discussed, and experiments are described which are being tried in various Orange-growing districts in the hopes of discovering a remedy. A Brazilian beetle is known to prey on the pest, but too much hope must not be based on this. We know that the ladybird at home fails to keep the aphis in check, and at present spraying seems to provide the best means of fighting it. The matter may unfortunately assume an interest for growers in this country, as the fly is stated to be rapidly increasing in the neighbourhood of Paris, where Apricots and Peaches are suffering seriously from its attacks.

THE RAINFALL IN 1907.—A number of correspondents have sent us information of the amount of the rainfall in their districts during the past year. We can only refer to the subject briefly, owing to the pressure upon our space. Mr. J. SHORT, writing from Freeland Lodge Gardens, near Woodstock, records a total rainfall of 28·09 inches, which fell upon 151 days. Mr. G. BENTLEY, Shugborough Gardens, Stafford, records 30.17 inches; Mr. J. B. LOWE, D'Abernon Chase Gardens, Leatherhead, gives a total for the year of 25.53 inches against 24·90, which fell in 1906. Our correspondent states that the heaviest fall occurred on August 17, and this amounted to 1 inch. October was the wettest month of the year in this district, and September the driest. Mr. H. PARR, Trent Park Gardens, New Barnet, states that the amount registered there was 24½ inches. Mr. J. B. ALLAN, Osberton Gardens, Worksop, informs us that the warmest day in 1907 was May 12, when the thermometer registered 83 in the shade; the coldest being January 24, when there was 21 of frost. The total rainfall was 21·18 inches, being 1.16 inches less than in 1906. Mr. W. A. COOK, Leonardslee Gardens, Horsham, registered the large amount of 25·94 during the year. Mr. THOMAS WYTON, Abbeystead Gardens, near Lancaster, the larger amount of 55.39½; Mr. FRED. LEACH, The Avenue Gardens, Bromppard Spike, Exeter, 31·62 inches; Mr. H. YOUNG, Shirenewton Gardens, Chepstow, Monmouthshire, 42.98 as against 39.34 inches in 1906. October was the wettest month, furnishing 7.85 inches. These gardens are situated 536 feet above the sea level. Mr. H. WILSON, Cold Orton Hall Gardens, Ashby-de-la-Zouch, registered a total of 29.53 inches at his observatory at 540 feet above sea level.

THE GARDEN CLUB OF THE FRANCO-BRITISH EXHIBITION.—The Garden Club now being formed in connection with the Franco-British Exhibition is under the direction of a strong committee, presided over by the Earl of JERSEY, and including, among others, Viscount SELBY, Lord ALVERSTONE, Lord BLYTH, Lord DESBOROUGH and Lord STRATHCONA. It will possess one of the most magnificent and commodious club houses ever constructed for a summer club in any part of the world, as may be gathered from the fact that the building has a frontage of 300 feet, and a depth of over 130 feet. Ladies are qualified for membership, and a special reception room and drawing-room, together with a suite of boudoirs, will be set apart for them in the club house, where the men will also be provided with a smoke room and several dressings rooms. The façade of the great dining hall is composed entirely of large glazed panels, and its doors and windows open directly upon gardens, in the centre of which is an ornamental sunken band-stand. There is likewise a spacious banqueting hall, nearly 100 feet long, and somewhat smaller rooms in which private dinner parties may be given by members, while on the lower floor and on the terrace above are numerous partly-closed spaces, which will be found suitable for small dinners and luncheons, in addition to a score of private dining rooms. The catering of the club has been placed in the hands of Messrs. LYONS & Co., whose charges will be on the same moderate scale as at the Trocadero Restaurant. The executive is to be congratulated on having made such a favourable arrangement, as it has been the custom in all previous exhibitions to add at least 25 per cent. to the cost of everything in the way of refreshments consumed in the grounds. It may be mentioned here that the prices at the restaurants and buffets throughout the exhibition will be the same as those which usually obtain outside it. The subscription to the club, which includes entrance to the exhibition, is three guineas for gentlemen, and two guineas for ladies, but for those living over 25 miles from Shepherd's Bush the subscriptions are respectively two guineas and one guinea and a half.

SOCIETE FRANCAISE D'HORTICULTURE DE LONDRES. Referring to our report of the annual dinner of the above society in last week's issue, we notice in *La Chronique* (the only French paper published in London) a full report of the proceedings and an excellent portrait of HARRY J. VEITCH, Esq., F.L.S., V.M.H., who presided on that occasion.

BIBLIOGRAPHY OF THE CHRYSANTHEMUM.—To those of our readers who are interested in the Chrysanthemum from a literary standpoint, we may draw their attention to the very comprehensive bibliography of the flower compiled by Mr. HARMAN PAYNE, which appears in the December number of the journal of the National Horticultural Society of France. The article, which, we understand, will be issued in separate form, was prepared by request of the Chrysanthemum Committee of that society, and includes all the known pamphlets and treatises on the flower that have been published in Germany, England, Australia, Austria, Belgium, France, the United States, Holland, Italy, New Zealand, and Portugal.

LANTANA PERFUME. The common Lantana, which was introduced into Ceylon during the earlier part of the last century, has proved a very aggressive weed, taking possession of waste or unoccupied land wherever the climate is hot and damp enough for it to thrive. It forms impenetrable thickets, and is very objectionable to the traveller on account of the necessity of cutting a road through it, and the thorny character of the plant as a whole. A correspondent to the *Tropical Agriculturist* states that a planter in the Wynaad (western slopes of the Neilgherries in S. India) has succeeded in extracting a valuable perfume from the flowers. It is rather difficult to credit this, as most persons find the odour of the plant and flowers exceedingly disagreeable. Unless, therefore, the writer was mistaken in his identification of the plant, probably the essential oil undergoes some change in constitution during the process of extraction.

THE ACREAGE AND LIVE STOCK RETURNS OF THE BOARD OF AGRICULTURE AND FISHERIES is the important source of the statistical information on the relative proportions between the different kinds of agricultural products that obtain from year to year. Some of these statistics are of especial interest to some of us at the present time. It appears that the number of small holdings (i.e., from 1 to 5 acres) already forms nearly a fifth (21.46) of the whole number of holdings in Great Britain, and that, taking England alone, the proportion is very nearly the same. Of course, the proportion of *acreage* of small holdings is very much less. The total acreage under crops and permanent grass has changed but little during the last 20 years, if we make allowance for periodical fluctuations, but there has been a marked turnover from arable land to grass, which has been going on fairly steadily during the last 20 years. Thus there were nearly 3,000,000 acres less land under the plough in 1907 than in 1878. Doubtless this is partly due to the depreciation in the price of corn, and to the rise in labour. Grass land is cheaper to manage than is arable land, but its value to the community is also lower, and the rural population which it will support and employ is considerably smaller. It remains to be seen how far legislation is capable of influencing the economic conditions that have led to the existing state of things, but in connection with small holders, it may be noticed, that, as shown by the returns, the acreage under small fruit has steadily increased from 36,724 acres in 1888 to 82,175 acres in 1907.

ORCHID NOTES AND GLEANINGS.

CYPRIPEDIUM MINOS, YOUNG'S VARIETY

OUR illustration (fig. 35) represents a flower of this beautiful hybrid between Cypripedium Spicerianum and C. Arthurianum (Fairrieanum × insigne), reproduced from a photograph, of the specimen for which Messrs. J. & A. A. McBean, Cooksbridge, Sussex, obtained a First-Class Certificate at the Royal Horticultural Society on January 14 this year. The variety was raised a good many years ago by the late Reginald Young, of Liverpool, and has been shown on several occasions, but failed to get the highest award, although many experts deemed it worthy. Messrs. McBean showed the plant at its best, and at last succeeded in obtaining a First-Class Certificate. The dorsal sepal is white, tinged and veined with purplish-rose from a small green base. The petals and lip are of a shade of honey-yellow with red-brown.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

WHAT IS AN HERBACEOUS PLANT?—Although it may not be altogether an easy matter to decide whether a certain plant is "herbaceous" or not, surely there can be no doubt as to the meaning of the word "herbaceous" itself? Perhaps the simplest and plainest definition of "herbaceous" is *non-woody*. Consequently trees, shrubs, and under-shrubs cannot be "herbaceous." Last year I had occasion to object to the following remarks in the official report of the R.H.S. examiners in connection with the school teachers' examination, viz.: "Several candidates stumbled over the term 'herbaceous,' using Carnations, Pansies, and other evergreen plants as illustrations." I asked the secretary of the R.H.S. whether an "evergreen" plant henceforth was to be barred from being "herbaceous." The question was evaded, and I was referred to some indefinite but well-known stock definitions as to the word "herbaceous." My special attention was also drawn to the R.H.S. "Rules for Judging," Sec. 179, in which it is stated that "herbaceous are (*sic*) plants with stems which die down yearly, but having root stocks remaining alive through several winters." I was also referred to Sec. 180, which defines "Carnations, Pinks, Arabis, Thrift, &c., and also "tufted evergreens which do not die down in winter," as "suffruticose"—that is, "plants of a more or less shrubby growth." It is obvious from these quotations that the R.H.S. "Rules for Judging" require amending. At present, because an herbaceous plant happens to be *evergreen*, the R.H.S. "Rules for Judging" make it into a "plant of a more or less shrubby growth." Fancy such evergreen plants as Meadow Grass, Pansies, Violas, Thrift, Arabis, Aubrietias, Houseleeks, Daisies, Cerastium, Stachys lanata, Spiræa filipendula—not to mention many others—being "suffruticose." The thing is ridiculous. It also appears from the "Rules for Judging" that the mere adjective, "herbaceous," implies that a plant must be "hardy" as well as "perennial." So that annuals and biennials—which are, of necessity, "herbaceous"—are excluded from the group to which they naturally belong. As every qualified gardener knows, an herbaceous plant (*i.e.*, a *non-woody* plant) may be either "hardy," "half-hardy" or "tender"; it may also be "deciduous" or "evergreen"; and again it may be "annual," "biennial," or "perennial" in its nature. Each group may be subdivided in other ways, if necessary. Thus "hardy herbaceous perennials" may include (i.) such bulbous plants as Liliums, Tulips, Daffodils, Hyacinths, &c.; (ii.) tuberous-rooted plants like Dahlias, Anemones, Ranunculi, Artichokes, &c.; and (iii.) those with fibrous roots. So far as the discussion in your pages has gone, surely because a woody plant like the Fuchsia, for instance, gets killed down by the frost, it does not become herbaceous. It is naturally a woody plant when properly developed, and will add new wood each year to its frame under normal conditions. It is a mere accident that the plant cannot stand our winters in all parts, and has to start afresh each year. The same may be said of many other woody plants. In the great winter of 1879 and 1880 I think many exotic trees and shrubs were killed down to the ground by the frost, but new growths were afterwards developed from the uninjured perennial root-stock. I fear if we were to leave the word "herbaceous" out of schedules, as Mr Jenkins suggests, it would be possible to include any tree or shrub—big or little—as a "hardy perennial" at least, if not a "hardy border perennial," and then the judges would have a lively time of it. *J. Weathers.*

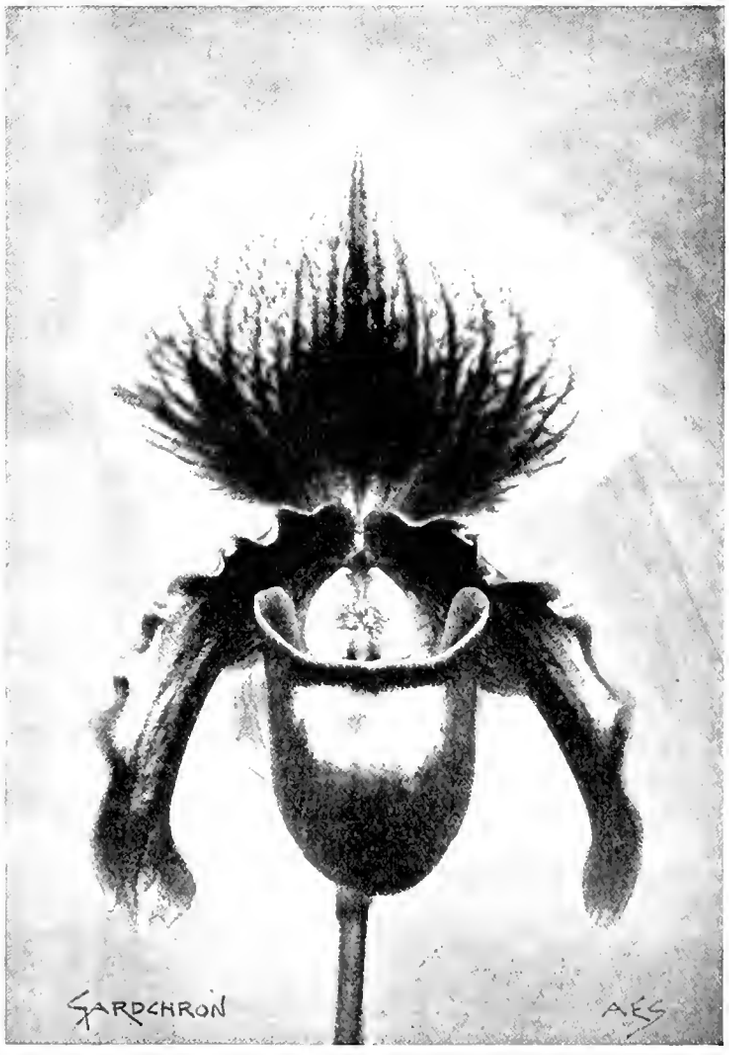

FIG. 35.—CYPRIPEDIUM MINOS, YOUNG'S VARIETY.

HERBACEOUS PERENNIALS.—It is to be hoped that compilers of schedules for flower shows will ponder seriously before altering their schedules as suggested. The schedule-maker knows best what he wants and has a perfect right to get what he asks for and nothing else. In asking for herbaceous perennials, or hardy herbaceous perennials, it is clear that Romneya Coulteri, Phygelius capensis, Fuchsia Riccartonii, Canterbury Bells, and Sweet Peas are not what is wanted, viz., herbaceous perennials; therefore they must be excluded from this class. The mere accident of a plant not being everywhere hardy does not alter its character. You mention that Pansies would be excluded, and rightly so. They would, no doubt, appear in their proper place. *R. L.*

NUMBER OF SPECIMENS IN EXHIBITS OF VEGETABLES.—On p. 43 *H.K.* brought to notice a much-needed reminder to schedule-framers and committees of flower shows. Not only many of the lesser societies, but a goodly proportion of the leading provincial societies (including the Shropshire Horticultural), fail to place any limit to the number of specimens necessary for individual dishes in collections of vegetables. A few societies limit the exhibitor to the same number as they state for single dishes. This arrangement with some varieties makes a fair display, but take the case of Cauliflowers, three specimens being usually called for in single dish classes. This number would look sadly deficient at the back of either a six or a nine variety class, and the same might be said of several other vegetables if staged under a similar restriction. To state a case: the first and second prize winners in the champion class at Shrewsbury last August staged ten and six Cauliflowers in their respective collections of nine distinct kinds of vegetables. Now, supposing these two collections had been equal in excellence, and points given to that effect, would the fact of the one staging ten Cauliflowers, and the other only six, have carried any weight with the judges, seeing that the arrangement of both collections left nothing to be desired? Neat and effective staging is sometimes taken into consideration in a close contest, and properly so, as the appearance and difference between a well-finished collection and a slovenly one, even if the vegetables are of equal merit, is only too apparent to everyone interested in the growing and showing of good vegetables. *B., South Devon.*

RAILWAY RATES.—The article by Mr. H. Morgan Veitch, published in the last issue of the *Gardeners' Chronicle*, is to the point, but it is not overdrawn. It is quite time the Government and the railway companies realised that market-gardeners and nurserymen have built up one of the most important of our national industries, and one that would immeasurably benefit all concerned, from grower to consumer, if it was given reasonable encouragement instead of being penalised by another industry, viz., the railways. They are useful—so are we—and we should be more beneficial still to the public if we received fair treatment. Is it not a farce that one industry should dictate terms to another without an opportunity of getting any benefit by competition? The state of the matter is shortly this. A farmer has land and grows Wheat, which the railway will carry a certain distance for 8s. per ton, and will find warehouses and men to handle it several times, and must protect it from wet, or it is spoiled. If that same farmer goes to greater expense and grows fruit, the railways compel him to pay them three times as much carriage, whilst they give the produce less attention, and are put to no expense for warehouses. If he spends still more, building glass to protect his crops, and becomes a customer to the railway companies practically all the year through, he must pay still more. Why there need be such a complicated classification passes any sane man's comprehension, as it costs no more to haul a truck load of fruit or Tomatos than a truck of coal. Now, let us look at the benefit of the trade to the railway companies. If Wheat is grown they get about two tons to the acre, if Potatos, at least six to eight tons, and so on, in increasing amounts, until I leave your readers to work out the tonnage grown under glass, and the immense trade in other ways brought to the railways in coal, manure, building materials, &c., besides extra passenger traffic. When Sir Charles Owen explained to the L. & S.W.R. shareholders that the lower dividend for 1905 was caused by the bad crops of fruit in the Channel Islands, and also of Potatos in France, he gave the game away, as firstly, he acknowledged that our "insignificant" trade could affect the railway companies' dividends; secondly, there were good crops in the Channel Islands, but, owing to the oppression of the L. & S.W. Railway and G.W. Railway companies, after they had combined, the growers pluckily joined together and formed "The Guernsey Mutual Transport Company," which took £20,800 in 18 months, every penny of which came out of the railway companies' pockets; thirdly, Potatos were a larger crop than usual in France, but, owing to the bad delivery, the salesmen chartered their own steamers, and got a much better service. Crops were good for the grower and for the salesman in both cases, but bad for the railway companies, owing to their own mismanagement. This shows what can be done in some cases, but there are many others in which there is no possibility of doing without the railway companies, and the last chance of retaining some competition between the different companies is being done away with by the system of combining, which is becoming more and more prevalent every year. We contend that, for their own benefit, they should encourage a trade and not stifle it, and their shareholders should protest against their revenues being diminished by such unbusinesslike methods. What will be left in country districts for their goods trains if they succeed in handicapping their market-gardening carrying trade out of existence? It is stated that the fact of raising the rates on Potatos from Lincolnshire to London, which they were allowed to do by the Railway and Canal Commissioners, has resulted in about £30,000 less freight through hundreds of acres going out of cultivation as far as that produce is concerned, another instance of their blind folly. The Prince of Wales said that Englishmen must "wake up," and that applies more particularly to those on the horticultural side of agriculture, if not to agriculture generally. I am pleased to state that a good proportion of the nurserymen have subscribed to the Joint Railway and Parliamentary Committee, representing other perishable foods as well as fruit, and I hope that all will do so, as it is clearly a case where union would be strength. It is only by showing a united front that we can succeed in getting better treatment. I apologise for taking up so much of your valuable space. *Geo. Morse, President of the Joint Railway and Parliamentary Committee.*

BRANCHES OF THE B.G.A. The executive council desire to inform gardeners that they are prepared to support efforts to form branches in any part of the United Kingdom. They will on application arrange to send a delegate to address the meeting, provide handbills for distribution, and pay the initial expenses for hiring a room. In the case of the establishment of a branch, with a properly constituted committee and secretary, the council are prepared to assist the branch with the necessary stationery and literature. The executive council also suggests that at least four meetings be held during the year, and, if possible, papers of general gardening should be read, in addition to the general business of the branch. The secretary of each branch is also invited to send up reports embracing any items of gardening interest in addition to the reports of business done. A branch of the B.G.A. may be formed wherever a mutual improvement society (composed of professional gardeners) exists. *J. Weathers, Secretary.*

THE FLORISTS' ART.—Those people who bewail the want of taste in floral arrangements should be able to lay down principles for the benefit of the ignorant. I believe that until any individual has acquired a distinct impression in his mind of the attributes of beauty in form and colour; or, in other words, has an educated eye to perceive what is appropriate, he cannot make the most of the material at his command. This so-called good taste is to a certain extent inborn, but it can be acquired, not as *F. M.* (see page 439) would have us believe by imitation of other people's work, but by cultivating the feeling for all that is beautiful in nature and art. Decorative work (I do not mean bouquet or wreath-making, or any such artificial methods of the professional florist) is practised daily in all country houses of any pretensions. *A. H.* writes ignorantly when he says that gardeners have, as a rule, little practice in this work. I have seen quite as good decorations, on special occasions, in houses and churches (carried out with but limited materials) as any professional florist could supply. Arrangements that give pleasure and satisfaction to one's employer and his guests cannot fairly be termed failures. Whatever some people may say, "taste" has been analysed and explained and it has fixed rules and principles that cannot be ignored in the world of nature and art. It seems to be forgotten by those who advocate flower-show arrangements as models, that such places lack the artistic background and accessories found in the rooms of a private house, and these are of as much importance as the plants and flowers themselves. *F. Street, Ardwell, Wigtownshire.*

———Some of the groups to be seen at the shows give excellent colour effects which might be useful in a conservatory or winter garden, although too elaborate for some of the cramped positions which private gardeners are often called upon to decorate. I have sometimes had a fireplace pointed out to me, the hearth not more than 2 feet wide, with instructions to make a nice group of plants, with some good Palms at the back; but the plants must not project over the raised stonework in front, or the dancers would knock them over. There was not much room for rustic bridges, pretty Bamboo stands, imitation lakes, cork, &c. Moss and suitable plants, and foliage to hide the pots, had to be used instead. I quite agree with *A. H.* (page 30) regarding the danger incurred by exhibitors in breaking away from the old-established designs, the would-be pioneer running a serious risk of being rewarded, not with the laurel wreath, but with the wooden spoon. I also agree with him about the shower (?) bouquets, many of them being like some November showers—rather heavy. *F. M.* (p. 439) seems to think very little of our efforts at table decoration, but has he considered the difference between a table at many of the exhibitions, with plenty of room to make an effective design, and that of many dining-rooms, loaded with all manner of things before the gardener starts his work? I have looked at many of the former in the hope of getting some new ideas for home decoration. These tables generally had a more or less elaborate centre-piece, and the design carried from it to each corner, instead of the tall lamp, surmounted by a sunshade, and surrounded by the usual two silver mugs and four ornamental spoons, while the space from the centre to each corner of tables I have had to decorate was generally occupied by a regulation design of water bottles, menu cards, salts, peppers, &c., the remainder, except about 10 inches all round for places, often being well covered by squat dessert dishes, sweets, preserved ginger jars, &c. Let us have some tables of this sort at the shows, and then we shall doubtless witness something instructive, which would be doubly so if we could see the same table dressed night after night with different designs, in the way that many of us have to do in private establishments. I should not think that any gardener who had the slightest knowledge of table decoration would use any other than suitable foliage and flowers for artificial light. The one thing in which I am inclined to think that some gardeners fail, in comparison with florists, is in the making of floral tributes for interments, those gardeners who have not had the opportunity of seeing and handling some of the finest florists examples generally making them too dense and flat. The letters on this subject have reminded me of an incident which occurred not many years ago. I had the flowers to arrange in a moderate-sized drawing-room; there were just 36 vases in this room (much against my wish), ranging from small glasses with one Rose bloom, to large jugs with such flowers as Pæonies, the latter perched on stands about 6 feet high. A visitor, after a critical survey of this exhibition, remarked that flowers were all very well in their way, but this room reminded him of nothing so much as a "florists shop." *Oxfordshire.*

SOCIETIES.

ROYAL HORTICULTURAL.

JANUARY 28.—The society's hall was on this occasion better filled than on the last one; flowering subjects being exhibited in larger quantity, more especially Orchids, Cyclamens, and Primulas.

Floral Committee.

Present: W. Marshall, Esq., and Messrs. Chas. T. Druery, Henry B. May, Jas. Walker, Walter T. Ware, G. Reuthe, J. W. Barr, R. C. Notcutt, R. W. Wallace, C. Blick, F. Page Roberts, Jas. Hudson, R. Hooper Pearson, Arthur Turner, W. Cuthbertson, Herbert J. Cutbush, W. P. Thomson, T. W. Turner, E. H. Jenkins, W. J. James, and Edwd. Mawley.

Messrs. SUTTON & SONS, Reading, showed an extensive collection of Cyclamens, which included White Butterfly, Giant Salmon Pink Superb Fringed, in variety, crimson self, and white, with crimson edge; deeply and lightly fringed; and purple, any of which is a pleasing change in form and in colouring. There were also specimens of C. Papilio, the winged Cyclamen; C. Salmon Pink, of lesser size than Giant Salmon Pink. The plants were dwarf, compact, and well-flowered, with small, stocky leafage, not in the least degree drawn up by warmth. The exhibit was backed with small Grevilleas, and in front were Isolepis gracilis. (Silver Floral Medal.)

The GUILDFORD HARDY PLANT NURSERY, Millmead, Guildford, exhibited a collection of species of Veronica not in flower, but interesting, as showing habit, foliage, &c. The varieties shown were V. decumbens, V. anomala, V. pinguifolia, V. macroura, V. Newryensis, V. ligustrifolia, a seedling with white flowers, and evidently an early blooming variety; V. cupressoides, V. Kirkii, V. carnosula, V. Stuartii, V. decussata, V. epacridia, V. Hectori, V. buxifolia, and V. rakaiensis. Other exhibits consisted of Andromenda calyculata, several hardy European Ericas, Rhododendron myrtifolium, with leaves of a claret tint, &c.

Ferns were largely shown by Messrs. H. B. MAY & SONS, The Nurseries, Upper Edmonton, in the usual capital manner of this firm. Notable specimens were Nephrolepis exaltata superba, Platycerium alcicorne majus, P. Stemmaria, Davallia Veitchii, D. retusa, Pteris Childsii, Lomaria ciliata, Asplenium Veitchii, Nephrolepis todeoides, Platycerium Hillii, and Nephrolepis Whitmanii. This firm exhibited some handsome Dracænas, viz., D. marginata rosea, D. Monarch, D. His Majesty, and D. Edith May; Codiæum Baron F. Selliere, with a yellowish white midrib and edge, and C. B. Comte, a green leaf irregularly blotched with yellow. (Silver-Gilt Banksian Medal.)

Messrs. W. CUTBUSH & SONS, of Highgate and Barnet, showed forced plants of a hardy nature, inclusive of Pyrus Malus floribunda, Magnolia Lenne, M. conspicua, Prunus triloba, Rhododendron Jacksonii, blush-white small flower trusses, Orange bushes, small Conifers, such as Retinosporas, Cryptomeria elegans, and Thuiopsis borealis compacta. There were some Cork boughs filled with flowering plants of Iris reticulata, I. Danfordii, I. Sindjarensis of a cerulean-blue tint, I. Histrio, &c. A number of Tree Carnations were also shown as pot plants and cut blooms, viz., Lilian Pond, a white, fairly double flower of good substance; Mrs. Burnett, Saint Louis (a bright scarlet), My Maryland (white—a robust flower), and The President. (Silver Flora Medal.)

Messrs. JOHN PEED & SON, West Norwood, London, S.E., exhibited Cacti, succulents, Sempervivum species, Sedums, Saxifragas, hardy Primulas; the new stellate Primula named Streatham, a pyramidal habited P. sinensis, the blooms of which are very thin in substance, but they make a good show. There were shown plants of P. obconica grandiflora, with flowers of various tints.

Mr. H. BURNETT, Carnation specialist, Forest Road, Guernsey, exhibited a number of choice varieties of Carnations, long-stemmed, as the fashion of the day decrees they should be. Many of the less recent varieties were included in the exhibit, and some that were new, viz., Miranda, white, suffused with faint pink; Aurora, a fancy with crimson flakes on a pale-yellow ground; Marmion, scarlet edged with white; and a number of beautiful novelties, which we hope to inspect later. The variety Mrs. H. Burnett was finely shown, as also Pink Enchantress. (Silver Banksian Medal.)

The Misses HOPKINS, Mere Gardens, Shepperton, exhibited rock plants; also some tubers of Tropæolum tuberosum, grown at "Mere."

Messrs. H. CANNELL & SONS, Swanley, Kent, were the exhibitors of 60 plants of varieties of Primula sinensis, the flowers of which in many instances are 2 inches in diameter, with overlapping petals that are wavy and dentate. The colour ranged from white, through rose, crimson, and blush to purplish-crimson and deep crimson. (Silver Flora Medal.)

Mr. L. RUSSELL, Richmond Nurseries, Richmond, Surrey, showed Aucuba japonica vera, Eleagnus picta aurea, E. macrophyllus, Eurya latifolia, Ivies, Buddleia asiatica, the exhibits differing but little from those that were observed at the previous meeting. (Silver Banksian Medal.)

Messrs. HUGH LOW & CO., LTD., Royal Nurseries, Bush Hill Park, Enfield, showed excellent Cyclamen grandiflorum, Salmon King and C. giganteum in varieties, plants in flower of Euphorbia jacquiniæflora, and a large number of Carnations in stands and glasses. (Silver Banksian Medal.)

A small exhibit of hardy flowers and plants came from Messrs. BARR & SONS, King Street, Covent Garden.

Alpine plants, such as Saxifragas, Hellebores, Colchicums, Snowdrops of species, hardy Ericas, Sternbergias, Hepaticas, Cyclamen, &c., were shown by Mr. G. REUTHE, Hardy Plant Nursery, Keston.

Messrs. J. WATERER & SONS, LTD., American Nursery, Bagshot, showed a large number of varieties of Holly, representing the best of these. They were mostly in pyramidal form, a few round-headed ones only being inserted in the group. There were several yellow and red-berried plants loaded with fruits. The yellow variegated green Holly "Moonlight" is a very distinct, showy variety. (Silver Flora Medal.)

Mr. T. ERNEST WALTHAM, 97, Upper Tulse Hill, S.W., showed several coloured stereoscopic slides of Rhododendron flowers. The process is so far perfected that the venation and texture of a flower or leaf are reproduced faithfully. The flowers reproduced were crimson and white ones, and nothing seemed lacking in the effect produced. A scarlet Gladiolus spike was likewise shown.

A Bronze Banksian Medal was awarded Mrs. MILLER for floral studies in water colours. The following subjects were very pleasing: "A Water Garden," "Sweet Peas," "A Marlow Garden," "Golden Pomp," the season "Autumn," with masses of Helianthus, Tritomas, Gaillardia, and other flowers of that season; "Bastion Steps," overgrown with Rambler Rose; "Rhododendrons at Howth," a wilderness scene of Ferns and flowers; "A Garden is a Lovesome Thing," this latter representing a wide herbaceous border filled to its fullest capacity with flowers, blue the predominant note, as given by Larkspurs and Borage. "The Other Side of the Latch" was a pretty bit of perspective.

A Silver Flora Medal was awarded Miss FARRER, Shaa Road, Acton, London, W., for floral studies that showed considerable technical knowledge, truthful colouring, and accuracy of drawing. The exhibits consisted of 10 pictures of flowers.

A Bronze Banksian Medal was awarded Miss SUMNER JONES, "Sherborne," Wellesley Road, Chiswick, for water-colour drawings of garden flowers very true to nature.

AWARD OF MERIT.

Nephrolepis exaltata var. Amerpohlii.—This is another plumose variety of the popular Nephrolepis, of dwarfer habit than the others. It is very compact, and the fronds are said to become 4 inches in depth, so plumose is the development. Shown by Messrs. H. B. MAY & SONS.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshay, H. Little, W. Boxall, A. A. McBean, J. Wilson Potter, F. J. Hanbury, R. G. Thwaites, F. M. Ogilvie, W. Cobb, W. H. Young, A. Dye, W. P. Bound, H. G. Alexander, H. A. Tracy, W. H. White, H. Ballantine, W. Bolton, R. Brooman-White, N. C. Cookson, C. J. Lucas, H. T. Pitt, and H. Graire, of Amiens.

Major G. L. HOLFORD, C.I.E., C.V.O., showed four new hybrids, of which the best was Cypripedium Merlin (insigne × illustre), the petals and lip of which were yellow-veined and tinged with red-brown; the very large dorsal sepal pure white, with a yellowish base bearing some dark purple spots. The others were C. Bianca (Prospero × insigne Sanderæ), a good flower, showing much of Prospero; Lælio-Cattleya Goldfinch (L.-C. Warnhamiensis × C. aurea), of a reddish gold colour; and Cattleya Cyril (Harrisoniæ × Percivaliana).

Messrs. CHARLESWORTH & CO., Heaton, Bradford, staged a fine group, at the back of which were some pretty hybrid Odontoglossums, good varieties of O. crispum, Lælia anceps, and other graceful varieties. In the centre were a selection of the clear yellow Lælio-Cattleya Andromeda, with two L.-C. Prospero, yellow with ruby front to the lip, and two of the reddish orange L.-C. Golden Oreole. At intervals were selections of the handsome Cattleya Octave Doin, C. Enid, and other showy hybrids. (Silver Flora Medal.)

Messrs. J. & A. A. McBEAN, Cooksbridge, staged an extensive and well-arranged group of finely-grown Odontoglossum crispum, and white varieties of Lælia anceps, chiefly L. a. Schroderiana, and Sanderiana. An attractive feature in the group was made by mingling many specimens of the dark scarlet Epiphronitis Veitchii with the white flowers of the other plants in the group. (Silver Flora Medal.)

Messrs. JAS. CYPHER & SONS, Cheltenham, had an effective group of fine Cypripediums, which included the handsome C. George Moore, C. Mrs. Bostock, a very large flower with the petals and lip like C. villosum giganteum, and with a fine apple-green dorsal sepal, bearing black spots, the margin being white; a very good selection of C. Euryades, C. aureum, C. Leeanum, C. insigne, &c. Colour was given to the group by good examples of Cattleya Trianæ, that named Princess Ena being white, delicately tinged with rose. In the centre was a grand example of Cymbidium Winnianum, with 10 spikes, and some hybrid Calanthes, good Lælia anceps, &c., were included. (Silver Flora Medal.)

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, staged a very fine group, in which were several good forms of Cypripedium insigne, some plants of the original rose-tinted form of C. Helen H., and one of the new C. Helen H. variety Armstrongiæ, a very pretty cream-white flower with small violet spots; and other Cypripediums; also two varieties of the pretty Cymbidium Woodhamsianum (Lowianum × eburneo-Lowianum), and a selection of species including Bulbophyllum Godseffianum, and Odontoglossums, one O. Pescatorei, having a very distinct labellum bearing many small rose spots; various Masdevallias, &c. (Silver Flora Medal.)

F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), showed a select collection of fine specimens of Cypripediums, which included four very fine forms of C. Euryades, that known as Sir Trevor Lawrence's variety being a superb form with large white dorsal sepal marbled with purple at the back and spotted with purple and rose on the face. A fine C. Minos with seven flowers, a grand form of C. Mons. de Curte, three plants of the yellow C. insigne Sanderianum, and one of a new variety named Ochre King, with large flower of a greenish ochre yellow colour, were also included. (Silver Flora Medal.)

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, staged an attractive group, a remarkable feature in which was made by a large number of Cypripediums obtained by crossing fine forms of C. villosum and C. Euryades, the resultant plants varying in form and colour in the most extraordinary manner, some resembling the best forms of C. Euryades with fine white dorsal sepal spotted with purple and rose, and others having the dorsal sepal bright purplish rose with pure white margins, and many being intermediate between the two extremes named. The cross is named Countess of Carnarvon, and the best varieties are very handsome. Messrs. VEITCH also showed Brasso-Cattleya Orpheus, variety

rosea, some good specimens of the fragrant and pretty Trichopilia suavis, a plant of Neobenthamia gracilis with a head of pure white flowers, varieties of Odontoglossum Pescatorei, &c. (Silver Banksian Medal.)

Messrs. MOORE, LTD., Rawdon, near Leeds, staged a nice group, principally of fine Cypripediums, among which were the leading forms of C. aureum, including strong specimens of Monarch and virginale; an exceptionally fine form of C. Charlesianum, and a good plant of the allied and favourite C. Ville de Paris; C. Saturn and a very pretty and finely-coloured hybrid between C. Leeanum Albertianum and C. insigne Chantinii. Also in the group were several showy hybrid Odontoglossums, one having the inner halves of the segments almost entirely of a rose-purple colour. Among species the singular Bulbophyllum comosum, with two drooping heads of hairy white flowers, and the singular yellow and purple Maxillaria porphyrostele were noted. (Silver Banksian Medal.)

Messrs. HEATH & SONS, Cheltenham, had an interesting group of Cypripediums, Cattleya Percivaliana, &c. Among the Cypripediums were the handsome C. Mrs. Wm. Mostyn, Chardwar variety; the finely-shaped C. Aureole (Lathamianum giganteum × Boxallii) with flowers of thick texture, the emerald-green dorsal sepal bearing rows of blackish spots, the margin being white; C. Charlesworthii roseum, an insigne variety, with white dorsal sepal, the lower half delicately tinged with lilac-pink from a small green base; good C. Mons. de Curte, and many fine plants of C. Leeanum giganteum. (Silver Banksian Medal.)

Messrs. HUGH LOW & Co., Enfield, staged a neat group, in which were Cypripedium aureum, Surprise, Œdippe, virginale, Hyeanum, and others. C. Thompsonianum, C. Swinburnei magnificum, and other Cypripediums; four plants of the bright rose Lælia Gouldiana, Odontoglossum blandum, varieties of Oncidium ornithorhynchum, one being white tinged with lilac, Arpophyllum spicatum, Cymbidium Wigianianum, &c. (Silver Banksian Medal.)

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), showed the new and fine Cypripedium Rajah (Io grande × Swinburnei magnificum), a large flower of very thick substance and attractive colouring. The large ovate acuminate dorsal sepal is white on the upper half, greenish-white at the base, from which radiate small blackish lines. The middle area is bright rose, with darker lines. Petals large and broad, dark rose-red, with several large raised black spots furnished with hairs on the margin. Lip large, brownish rose.

Messrs. LINDEN & Co., Brussels, showed Odontoglossum crispum "Jean Linden," the magnificently-blotched home-raised variety, which was illustrated in the *Gardeners' Chronicle*, December 22, 1906, p. 418, but now greatly improved; the pretty O. Notteanum (Loochristiense × Wilckeanum); O. exultans variety formosum (crispum × excellens), a large yellow flower, handsomely blotched with red-brown; and three Cypripediums, the result of seeding from forms of C. insigne.

AWARDS.

AWARD OF MERIT.

Cypripedium Fairrieanum, Cookson's variety, from NORMAN C. COOKSON, Esq., Oakwood, Wylam (gr. Mr. H. J. Chapman). A superb variety, and the darkest which has yet appeared, almost the whole of the dorsal sepal being of a deep claret colour, only a little white showing through in small patches at the base. The reverse of the dorsal sepal is coloured like the face, and the rest of the flower is also very dark. Mr. COOKSON showed another equally dark form with an undeveloped bloom.

Cypripedium F. Sander, from FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins). A very remarkable Cypripedium, the origin of which is somewhat obscure. The leaves, which are narrow and pointed, have a very thin dark-green reticulation. The flower, which is of fine form, has a showy and flat dorsal sepal of pale emerald-green, densely blotched with large glossy chocolate-brown blotches, the upper part being white with purplish spots, as in some of the best forms of C. nitens. Petals and lip well-formed, honey yellow tinged and veined with chocolate-purple. Staminode large, yellow.

Cymbidium Gattonense (Lowianum × Tracyanum), from Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate. A very worthy production, with flowers as large as those of C. Tracyanum, but deeply coloured and marked as in the best C. giganteum. Sepals and petals greenish-gold colour, closely lined with purplish red. Lip broad, cream-white, marked with red, and having a hairy disc as in C. Tracyanum. The cross is interesting, as it disproves the supposition that the natural hybrid C. Ansonii is of this parentage.

Fruit and Vegetable Committee.

Present: George Bunyard, Esq. (chairman), and Messrs. W. Bates, Alex. Dean, W. Pope, R. Lye, Geo. Kelf, H. Parr, J. Davis, G. Reynolds, James Vert, Owen Thomas, C. G. A. Nix, W. Poupart, Jos. Cheal, and A. R. Allan.

Messrs. J. PEED & SON, nurserymen, Roupell Park, West Norwood, displayed a considerable number of Apples, showing signs of careful attention to their cultivation in their generally fine size and freedom from blemishes. There were very fine specimens of the varieties Bismarck, Withington Fillbasket, Lord Hindlip, Dumelow's Seedling, Blenheim Pippin, Lord Derby, and Alfriston. (Silver Knightian Medal.)

A splendid exhibit of Potatos, chiefly kidney-shaped varieties, was shown by Mrs. DENISON, Little Gaddesden (gr. Mr. A. G. Gentle). Their only fault lay in the general large size of the tubers. Other exhibits from the same garden were bulbs of Cocoanut, Ailsa Craig, and Record Onions. These were simply enormous. (Silver-Gilt Knightian Medal.)

LECTURE ON SELF-COLOURED PHOTOGRAPHY.

The lecture given at this meeting was one on "Self-Coloured Photography of Switzerland and Swiss Flora," given by Mr. T. Ernest Waltham, and illustrated some new and combined processes of his own invention for obtaining photographs in purely natural colours. The Chairman (Mr. A. W. Sutton, F.L.S.) expressed the hope that the lecturer would kindly give his hearers some idea of his mode of working, for their possible guidance, but this, in view of impending patents, was, Mr. Waltham explained, hardly practicable. The slides indicated by the title of the lecture were preceded by a number of others, and illustrated firstly a magnificent series of floral photographs embracing Cactus Dahlias, Cattleyas, Dendrobiums, representing fine types, in natural colours, and of amusingly exaggerated dimensions, but beautifully exemplifying the capacity of the art of reproducing apparently the thing itself instead of merely a monochrome picture in black and white. Some interesting views of Holland House and the Japanese garden there were followed by some of Wisley, where a grand specimen of Spiræa Aruncus in full bloom, Gunnera scabra of gigantic dimensions, and several general views embracing a neat one of the Water Lily pond, were so well brought out that the onlooker actually seemed to be present in the garden. The views in Switzerland were grand, commencing with winter scenes taken after heavy snowfalls, where snow-laden Conifers, picturesque old châlets, and bold rock-effects amid deep drifts seemed to transport the beholder to the heart of the Alps, some imposing views of glaciers adding to the illusion. Having thus given a general idea of the conditions under which Alpine plants thrive in their native habitats, a series of extremely interesting slides followed, showing a number of the species in their natural habitats, Epilobium rosmarinifolium, Dryas octopetala, Silene (Gypsophila) repens, the Martagon Lily, Holly Fern, and Green Spleenwort, yellow Aconite, Gentiana lutea, G. acaulis, and G. bavarica, Rosa alpina, Ranunculus aconitifolius, Lychnis flos-Jovis, and yellow Foxglove being exhibited in their true colours amid associated vegetation of many kinds, some singly and others in groups precisely as nature assorts them in the bold, rocky fastnesses they adorn. Then suddenly the beholders were transported back to home again by a view of a woodland clearing carpeted with golden Primroses, but the next slide afforded a moonlight view of the Lake of Geneva; the lecturer frankly explaining that photographic moonlight views were really "moonshine" in the satirical sense, as they were actually taken by sunlight and toned down.

A series of six stereoscopic views by the lecturer of some of Messrs. Waterer's Rhododendrons was shown in the Hall, and revealed apparently the very flowers themselves, the double pictures giving an impression of substance which the lecturer regretted could not be imparted to views upon the screen.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

[The result of the election was published in our last issue.]

JANUARY 23.—The sixty-eighth annual general meeting was held at Simpson's, Strand, on the above date, Mr. Harry J. Veitch, treasurer and chairman of committee, presiding.

Following the reading of the minutes of the last meeting, &c., the secretary, Mr. G. J. Ingram, read the ANNUAL REPORT OF THE EXECUTIVE COMMITTEE as follows:—

The committee in submitting their annual report, together with a statement of receipts and expenditure (as certified by the auditors) for the year 1907, again have the pleasure of congratulating the subscribers and donors to the institution on its continued success.

At no former period in the sixty-eight years of its existence has so much been done in the way of affording permanent and temporary assistance to the unfortunate members of the horticultural community—gardeners, market growers, nurserymen, &c., and the widows of such—as during the past year. Over £4,000 has been disbursed in permanent aid alone. That this happy condition has obtained is a matter for thankfulness, and the committee feel it is also an encouragement to the subscribers and others whose generous liberality has enabled them to carry on the work with so much benefit to those who, through illness and misfortune, have been obliged to seek assistance from the charity, and have not sought in vain.

At the beginning of 1907 there were 227 pensioners on the funds—123 men and 104 widows—receiving annuities of £20 and £16 per annum respectively for life. During the year twenty have died, one man has been removed to an infirmary under medical orders; another, a widow, to an asylum owing to her mental condition, and another has left England for America to reside with her son. Of the men who died, three left widows, whose circumstances being such as to render them eligible, have been placed on the funds without election to receive the widows' allowance of £16 a year each for life, under Rule iii. 13. The committee now recommend an election this day from an approved list of fifty-two candidates, to fill the vacancies created. Fully sensible of the urgent needs of many of those who are appealing for aid, the committee sincerely wish they were in a position to assist a larger number, but this they feel cannot safely be done without the assurance of an additional income to meet the extra liability which would necessarily be incurred.

The "Victorian Era Fund" and the "Good Samaritan Fund" still prove a source of much benefit and comfort. From the former fund nearly £200 has been distributed amongst the unsuccessful candidates at the last election who had formerly been subscribers, in terms proportionate to the length of time they had subscribed, and from the latter fund £176 has been given in small amounts as temporary relief to numerous applicants—whether subscribers or not—whose cases were of a most distressing and pathetic nature. The committee again beg to draw attention to the value and utility of these two funds—the one helps the candidate awaiting election, whilst the other bestows temporary help in cases of emergency. As the income only from these funds is available, special contributions earmarked for either of them will be warmly welcomed.

The annual festival dinner which took place at the Whitehall Rooms of the Hotel Metropole on June 20th last, under the presidency of the Hon. Walter Rothschild, M.P. (trustee), was most successful, and resulted in a substantial sum being raised towards carrying on the work. The committee desire to place on record their gratitude and indebtedness to the chairman for his earnest advocacy of the claims of the charity, and for his generous contribution to the funds. They also take this opportunity to express their sincere thanks to those gentlemen who acted as stewards or collectors, to the contributors of flowers, to the horticultural Press for their gratuitous and invaluable help, to Mr. James Hudson, V.M.H., for superintending the decorations; and to other friends throughout the country who in any way, directly or indirectly, contributed to the gratifying result attained. Grateful thanks are likewise tendered to the Right Hon. Mary Countess of Rosebery, for again allowing her beautiful gardens at Holland House to be opened to the public on the occasion of the great summer flower show of the Royal Horticultural Society, part of the proceeds obtained therefrom being handed to the institution; also to the Right Hon. Earl Beauchamp, Madresfield Court, and Sir Frank Crisp, Bart., Parkfield, for similar kindnesses for the same object.

To the "Geo. Monro" concert committee they offer their acknowledgment for £210 contributing to the funds. Sincere thanks are likewise accorded to N. N. Sherwood, Esq. (trustee), for his gift of £50 to the unsuccessful candidates at the last election; and to Arthur W. Sutton, Esq. (member of committee), for kindly supplying a similar amount for a year's allowance in support of an incurably paralysed candidate. Very gratefully do the committee also acknowledge the services rendered by the hon. treasurers and hon. secretaries of the several auxiliaries which continue to be a source of strength and support, not only in obtaining additional financial aid, but in maintaining, as well as creating interest in, the operations of the charity.

It is with great pleasure the committee have to announce that the Right Hon. Lord Aldenham will preside at the sixty-ninth anniversary festival dinner in aid of the funds on Wednesday, June 24th next, at the Whitehall Rooms, Hotel Metropole. They hope his lordship will be warmly supported by every lover of gardening and flowers, and that the festival will prove as successful in furtherance of the cause of benevolence as those in previous years. The names of gentlemen willing to act as stewards will be much appreciated.

The committee, unfortunately, have again with sorrowful and melancholy regret to refer to the large number of losses by death amongst the friends and supporters of the institution they have sustained during the past year. They would especially mention the Marquis of Bristol and Maxwell T. Masters, Esq., M.D., F.R.S., both of whom were vice-presidents for over forty years, and took a keen and lively interest in the institution, Dr. Masters being always ready to help forward the work. Among others who have passed away are Sir Alex. J. Arbuthnot, chairman of committee for a short time some years ago, Mr. James H. Veitch, also formerly a member of committee, and Lord Battersea, the Hon. Mark Rolle, Sir Michael Foster, Baroness Burdett Coutts, Mr. J. Hill White, one of the founders and hon. treasurer of the Worcester Auxiliary, and Mr. R. B. Cater, of the Bristol and Bath Auxiliary.

The loss of these long tried and generous-hearted friends will be severely felt, and their vacant places most difficult to fill. Still, the committee feel confident that those who remain in their midst will not relax their efforts, but will do all they possibly can to obtain fresh supporters to take the places of those who have been removed.

With much gratitude the committee acknowledge the practical aid and sympathetic help afforded them in their work, and they now very earnestly appeal to every well-wisher of this National (unsectarian) Horticultural Charity for further exertions and interest on its behalf, so that the beneficial work which has been carried on with such signal success for the poor and needy for so many years may continue to be maintained.—HARRY J. VEITCH, Treasurer and Chairman of Committee; GEORGE J. INGRAM, Secretary.

Mr. Harry J. Veitch, in moving the adoption of the report and balance-sheet, referred to the work the institution had done during the past year. The number of pensioners on the books was larger than at any previous time, and a sum of £4,334 was disbursed. Reference was also made to the losses sustained by the institution during the past year in the death of some of its principal supporters, mention being made of the late Dr. Masters, Mr. J. Hill White, and others. The report was adopted.

Following the adoption of the report, Mr. Harry J. Veitch was re-elected treasurer, Mr. G. J. Ingram, secretary, and the retiring members of the committee, auditors, and arbitrators were also re-elected.

The meeting afterwards proceeded to the election of pensioners, and the result was briefly recorded in our last issue.

There were no fewer than 48 voting papers returned unsigned, and were, consequently, forfeited. These papers represented 355 votes.

January 21, 1908

THE FRIENDLY SUPPER.

In the evening a company of about 60 persons assembled at the "Friendly Supper," the chairman for the evening being Mr. Martin H. F. Sutton. After the loyal toasts had been received with enthusiasm, the chairman proposed that of "Our Institution—its continued prosperity."

Mr. Sutton said that "the Gardeners' Royal Benevolent Institution is a national institution, and is worthy of the deepest affection on the part of all those who know anything of its objects and its methods. On the front page of our toast list we are reminded that it has now reached the sixty-ninth year of its existence, or, to put it in another way, that it is within two years of attaining to the age of "three score years and ten," which has been stated to be man's allotted span of life. True though that undoubtedly was in days gone by, that limit is constantly exceeded now, though whether greater intellectual powers are concomitant with greater longevity is probably an open question. However that may be, there is one great difference between the individual and the subject of this toast, in that, while the individual in his 69th year has usually seen his best days, this institution was never more vigorous and prosperous than at the present day. During those years it has distributed no less than £117,000 in relief, and only those who are in close touch with the work or are privileged to see some of the letters of gratitude received can form any true idea of how deeply that relief has been appreciated. Its work has brought comfort and happiness into the lives of hundreds who would otherwise in many cases have been entirely destitute, and I feel sure I am within the truth when I say that all those relieved have proved worthy of the assistance the institution was able to give them. In reviewing the past then, we should be deeply thankful for all that has been accomplished through the kind help of many friends, but we cannot on that account be content to rest on our oars. Comparatively large though the income of the institution is, it is by no means commensurate with the needs of the deserving cases that are constantly brought before the committee, and a far larger list of donors and subscribers is needed than at present exists. I honestly believe that no class of the community is more worthy of help in time of trouble than the gardener: I would go further, and venture to say that no skilled labour obtains a smaller wage than does that of the gardener. Many years of patient plodding work are necessary before a man is competent to take charge of a garden of any size, and even when such a position is secured it is difficult for the holder to save a sum that will in any way meet the needs of his declining years. The Gardeners' Royal Benevolent Institution is therefore a very real boon to him; it brings help just where it is required, and it is worthy of the unstinted support of all. In proposing this toast I have the great pleasure of coupling with it the name of one who has done as much if not more than any living man for this great work. I give you the toast of the Gardeners' Royal Benevolent Institution coupled with the name of Mr. Harry Veitch."

Mr. Harry J. Veitch, in responding, stated the amount of money that had been distributed during the year, and testified to the progress the institution was making. At the same time, the needs of the case were progressive also, and the committee were certainly anxious as to the future. Many liberal supporters of the institution had been removed by death during the year, and it was therefore essential that new subscribers should be obtained and the income of the institution increased. It was gratifying that even so many as 21 fresh pensioners had been elected that day, and they were very grateful to Mr. Arthur W. Sutton and Mr. George Munro

for making that number up to 23. He (Mr. Veitch) was also pleased to announce that Mr. Sherwood had signified his intention to give a sum of £25 for distribution amongst the most necessitous cases. Other toasts included "The Committee, Honorary Officers, and Country Friends," proposed by Mr. George Paul and responded to by Mr. W. A. Bilney and Mr. Peter C. M. Veitch. "Our Chairman," proposed by Mr. Edward Sherwood, and "The Secretary, Mr. G. J. Ingram," proposed by the chairman.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

JANUARY 9.—*Committee present:* Messrs. E. Ashworth, R. Ashworth, Ward, Warburton, Shill, Sander sen., Cypher, H. Smith, P. Smith, Ball, Parker, Cowan, Keeling, and P. Weathers (hon. sec.).

There was a capital display of plants, Cypripediums being prominent in consequence of the competition for Messrs. Sander and Sons' Challenge Cup.

G. SHORLAND BALL, Esq., Burton, Westmoreland (gr. Mr. Herd), staged a good group of Cypripediums, to which a Silver Medal was awarded. Cypripedium × Earl of Tankerville was the most notable of the plants in this group, and was awarded a First-Class Certificate, a similar award being made to C. insigne var. Berryanum. C. × Hitchensiæ var. vivicans, C. insigne var. Thomas Mills, C. × nitens var. "Queen of Yellows," C. × Grovesianum, C. × aureum var. Eric, and C. × Francis received Awards of Merit.

H. J. BROMILOW, Esq., Rainhill (gr. Mr. Morgan), had a magnificent collection of Cypripediums, which was well worthy of the Silver-Gilt Medal awarded to it. A large number of the plants contained in this group have previously been certificated by the Society, and it is, therefore, unnecessary to enumerate them here. Cypripedium × Venus, Rann Lea var., was awarded a First-Class Certificate, while C. insigne var. Monarch, and C. × Archimedes var. Excelsior received Awards of Merit.

S. GRATRIX, Esq., Whalley Range (gr. Mr. Shill), gained a First-Class Certificate for Cypripedium insigne var. A. J. Balfour, a fine form produced by hybridisation of two varieties of C. insigne. C. × Prince of Wales, from the same collection, received an Award of Merit.

A. WARBURTON, Esq., Haslingden (gr. Mr. Dalgleish), competing for Messrs. Sanders' Cup, gained a Silver Medal, and in the competition for Thompson's Cup was awarded a Silver-Gilt Medal. Cypripedium × Mrs. Moseley, likewise C. × Leeanum var. Avalanche, and C. × Buchanianum, Warburton's variety, received Awards of Merit.

Messrs. CHARLESWORTH & Co., Bradford, exhibited a new hybrid, viz., Odontioda × Craveniana, a choice plant produced by Cochlioda Nœtzliana × Odontoglossum maculatum. (Award of Merit.)

J. MACARTNEY, Esq., Bolton, gained a Bronze Medal for Cypripediums, and a Silver Medal for a miscellaneous collection of plants. Cypripedium × St. Vincent and C. insigne var. J. Macartney received Awards of Merit.

J. H. CRAVEN, Esq., Keighley (gr. Mr. Corney), was awarded a Silver Medal for Cypripediums; C. × Juno, Craven's var., and C. villosum var. Mrs. Cary Batten received First-Class Certificates.

Z. A. WARD, Esq., Northenden (gr. Mr. Weatherby), sent an interesting group of plants, which was awarded a Silver-Gilt Medal. The group consisted principally of well-grown Odontoglossums, species and hybrids, and made a cheerful change from the large display of Cypripediums. Odontoglossum × Lambeauianum var. Jasper received an Award of Merit.

E. ROGERSON, Esq., Didsbury (gr. Mr. Price), gained an Award of Merit for Cypripedium Godefroyæ, Oakdene variety, which was shown with a few other good plants.

Mr. J. ROBSON, Altrincham, exhibited Cypripedium × Hera var. Madeline. R. FARRER, Esq., Carnforth (gr. Mr. Proudlock), staged a few good Cypripediums, the best of which was a fine specimen of C. × Leeanum var. Clinkaberryanum. J. CYPHER & SONS, Cheltenham, had a nice display of miscellaneous Orchids; some choice forms of Lælia anceps were noticeable in addition to a number of well-grown Cypripediums. (Silver Medal.) Messrs. KEELING & SONS, Westgate Hill, Yorks., were awarded a Bronze Medal for a miscellaneous group. Messrs. HEATH & SONS, Cheltenham, were awarded a Silver Medal for a group of Cypripediums. Mr. W. SHACKLETON, Bradford, received a Bronze Medal for a group, in which were a few plants of botanical interest. R. ASHWORTH, Esq., Newchurch, was awarded a Silver Medal for a nice group of Odontoglossums, with a few other plants added. Messrs. H. LOWE & Co. staged a small collection of Cypripediums. (Vote of Thanks.) Messrs. MOORE & Co., Rawdon, Leeds, were awarded a Bronze Medal for a group of miscellaneous Orchids.

ROYAL METEOROLOGICAL.

JANUARY 15.—The annual meeting was held on the above date at the Institution of Civil Engineers, Great George Street, Westminster, Dr. H. R. Mill, president, in the chair.

After the report had been adopted, the president presented the Symons Memorial Gold Medal to Monsieur Léon Teisserence de Bort, of Paris, which had been awarded to him by the council "in consideration of the distinguished work which he has done in connection with meteorological science, especially the study of the upper air."

The president then delivered an address. Dr. Mill is the Director of the British Rainfall Organisation, and he spoke of his own work, and dealt with the subject of "Map Studies of Rainfall." He said that the special problem which he had before him was to determine the normal annual rainfall of the British Isles in relation to the general configuration of the land, and to ascertain how the rainfall of individual years and months, and even of the constituent showers was related to the normal. The most useful method of working towards this end is by the preparation and study of maps of rainfall. He then described the methods which he adopted in preparing annual, monthly, and daily maps of the distribution of rainfall, and also referred to cyclonic and thunderstorm rains. The rainfall showed an unmistakable relation to configuration.

Dr. Mill, in conclusion, said: It happens that rainfall is not only the most difficult of all the meteorological distributions to map accurately, it is also the one which is of the greatest importance, for by rain the rivers are fed, and the rivers both water and drain the land. Every year makes clearer the vast national importance of accurate knowledge of the rainfall of a county, for the problem of the rivers is becoming acute. The growing populations of the great towns are tapping the upper waters and diverting the water from its natural channels, and at the same time they are polluting the lower courses with the waste of the factories and the streets. Toll is taken all along the banks of industrial streams for raising steam and carrying on the multitudinous processes of manufacture. There is sometimes anxiety as to whether the waterways can be kept sufficiently supplied to float the water-borne traffic or to fight the silting action of the tides, and there is growing alarm as to the possibility of fish traversing the depleted and polluted streams to reach their spawning beds. Of recent years the value of the water power which may be generated in the lonely and lofty places amongst the western heights of Great Britain, where the rainfall is large and unfailing, has been recognised, and chemical works for the production in electric furnaces of what a few years ago were rare substances are becoming familiar features in Wales and the Highlands. In Ireland, too, the rainfall is an unrecognised source of wealth which as yet has not been drawn upon to any appreciable extent. The increasing strenuousness of the struggle for the possession of large water supplies is producing in England, and especially in Wales, a great amount of local jealousy and strife, for the boundaries of parishes and counties coincide but rarely with water-partings, and the argument has been brought forward again and again that the rainfall of one county should not be diverted for the use of the inhabitants of another. The feeling is intensified when the boundary to be crossed is that of a historical division of national importance like the boundary between England and Wales; but I think that the map-study of rainfall can do something to suggest the lines on which such disputes should be settled. Although the exceptional deluges of a thunderstorm or a great depression fall with equal and impartial heaviness on the hills of the west or the flat plains of the east, the common everyday rains are precipitated on the high lands and in the mountain valleys which cross the track of the prevailing wind in much greater abundance than on level and low stretches of country. Most of the rain is borne to our islands from the Atlantic, and when it comes torrentially, it is of the air, and no boundary checks it; the largest annual falls come down on and near the watersheds, because there the land produces its maximum influence as a rain compeller.

From the high ground the rivers seek the plains, carrying off the excess of rainfall into the less liberally-watered districts. The Dee, the Severn, the Wye, and the Usk restore to England part of the rains which the Welsh mountains have abstracted as the air passed over them. The high rainfall of the whole Pennine districts sometimes, by circuitous routes across the comparatively dry plains of the east, swells the volume of fresh water that pours into the Humber. The Thames itself receives the comparatively high rains of the Cotswolds, the Chilterns, and the Downs, and forwards the water slowly through less and less rainy districts, until it reaches the sea in the driest part of England. Thus, I think, at least as good an argument can be drawn from this consideration of physical geography in favour of supplying the great towns of the east from the large precipitation of the west, as can be drawn in the opposite sense from the artificial divisions of political geography. It seems to me that care for the water supply of the country, coming as it does from the air that knows no bounds across the land, is by no means a parochial but, in the fullest sense, a national matter, and should be dealt with in the interests of the nation as a whole; the units of sub-division when such are required being the natural units of river basins.

BRITISH GARDENERS' ASSOCIATION.

AT the last meeting of the Executive Council, Mr. C. Foster in the chair, ten new members were elected, bringing the total up to 1,138. A discussion took place as to converting the quarterly *Journal* of the Association into a monthly publication. It was eventually decided in favour of a "monthly" after the next quarterly issue, which would complete the year, and subject to full details as to cost to be submitted at the next meeting. A resolution in favour of legislation in Parliament for the establishment of old age pensions was carried, and Messrs. Lewis and Little were appointed a sub-committee to watch the procedure and report any progress made. A sub-committee was also appointed to prepare a practicable scheme for the examination of gardeners, the details to be ready by the annual meeting.

ENQUIRIES AND REPLIES.

ASPIDISTRA WITH SPOTTED LEAVES.—The Aspidistra *T. C.* enquired about on p. 64 is an old and fairly well-known kind, its name being Aspidistra lurida punctata. It cannot be regarded as rare, yet at the same time it is uncommon, the reason in all probability being that its style of variegation renders it less effective for decorative purposes than either the ordinary green or variegated-leaved forms. In a catalogue published in 1876 by Messrs. E. G. Henderson & Son, of St. John's Wood, this particular variety is quoted at 3s. 6d. each. H.

MICROLOMA LINEARE (CORAL CLIMBER OF SOUTH AFRICA).—I have just received from a well-known importer of South African plants three good healthy plants of the above-named beautiful and gracefully growing plant received by him from Port Elizabeth, where it is found growing wild at the base of low, scrubby bushes, round the branches of which it twines its slender, wire-like stems, as shown by Harvey on the 92nd plate of the first volume of his

Thesaurus Capensis. The flowers are produced in bunches of from five to seven, and are of a tubular form and a bright crimson carmine in colour; hence its native name of Coral Climber. It is also known under the synonym of Ceropegia tenuifolia, as described by Thunberg. A lady correspondent who has seen it growing wild in its native country writes to me about it in the following laudatory terms: "Yes, I known Microloma lineare well, and it is very pretty, with clusters of small crimson-scarlet flowers of a waxy texture which shine like jewels. The seed-pods also are interesting, being full of the silk usual amongst Asclepiads. There is another variety, M. sagittatum, but it is not so ornamental as M. lineare." I shall be glad to hear if this plant has yet blossomed in the United Kingdom, and whether any readers of the *Gardeners' Chronicle* have seen it in cultivation. It is by no means new, having been introduced about 1823. *W. E. Gumbleton.*

BISULPHIDE OF CARBON FOR VINE BORDER.—Will any reader who has used bisulphide of carbon for destroying insects in a vine border kindly state what is a safe quantity to use to the cubic yard, and if this insecticide is non-injurious to the roots of the vine if applied when they are in a dormant condition? *W. H. D.*

WANTED A NUT-MILL.—The Nut-mill enquired about by Mr Bartholomew on p 48 of the last issue can be obtained at Mr. T J Pilson's, dried fruit merchant, 88, Gray's Inn Road, near the Holborn Town Hall, and the price is, I think, 2s 6d each *Correspondent*

——— The Nut-mills can be obtained from the Eustace Miles Restaurant Co., Ltd., Chandos Street, Charing Cross, W.C. Prices 1s. 6d and 3s 6d., postage extra A small book of recipes for the making of dishes of Nuts, &c., will be supplied gratis, if a stamped addressed envelope is sent I strongly recommend Mr. A. C. Bartholomew to procure both *T. W Cook, Talaere Gardens, Prestatyn*

Answers to Correspondents

AN ASPARAGUS PLUMOSUS PLANT IN BAD CONDITION: *H. Churchman.* The plant is literally starved. You should shake it out of the tub or pot, cut away all dead and dying roots and top growths, dividing the mass into three or four portions and potting each separately, letting the new soil—chiefly good loam—trickle down among the roots, making it firm as you fill up. Give a good application of water and place the plant in a moderately warm house for three months.

BACTERIA: *Curious and K. B., Malvern.* The benefit to be expected from applying the bacteria for leguminous crops depends on the condition of the soil. It is throwing money away to use it on soils that are already rich. These already are fully inoculated. The poorer the soil the more likely is benefit to accrue. But the matter is still in the experimental stage. Why not try a small plot, and compare it with the produce in untreated parts of your garden?

BLEEDING OF MUSCAT VINE: *A. K.* You cannot stop the flow of sap by any artificial means, but it will cease of itself some time after leaf-growth begins. If very excessive, it may cause a weakening of the vine, but nothing serious is likely to occur.

CHRYSANTHEMUMS: *Jno. F* You have certainly given the plants plenty of manure Your trouble probably arises from the fact that the plants yet to bloom have had to complete their growth late in autumn, and the shoots are insufficiently matured to produce good flowers If this is the case all the manure in the world will not put matters right, but an excessive use of them would have an effect contrary to that which you wish. It is not uncommon for Chrysanthemums which flower at the end of January or later to yield very small blooms such as you have sent us

FORCED ROMAN HYACINTHS: *H. Churchman* Apply water till the yellowing of the leaves shows that the year's work of the bulb is done, then afford less and less by degrees, and afterwards dry the bulbs off. Another way is to plant the pottuls of bulbs in the shrubbery border or in the turf of the lawn and let them die off naturally, marking the spot with a stout peg. They will afford a few flowers in the spring each year, but Roman Hyacinths are only successful in favoured districts.

FRONDS: *Asplenium.* The specimen is infested with common "Scale" insects. Cut off the fronds and thus cause the plants to make a fresh start.

GARDENER'S NOTICE: *Devonshire, Interested.* It is customary for head gardeners living on the premises to receive one month's notice terminating the engagement.—*L. B. W.* The matter would depend upon the construction to be placed on the first intimation that was given you, whether it was a notice or not.—*F. J. M.* We do not know that either of you could successfully claim more than one week's notice. If the cases were taken to the courts they would probably be decided in accordance with what could be proved to be the custom.

GLORIOSA SUPERBA: *E. H., Liverpool.* The tubers that are softening do not appear to be attacked by bacteria, and we fail to detect the cause of the failure. These soft parts are soon covered with the common blue mould, which has always been regarded as a saprophyte. It is possible that sometimes it may become parasitic. We have inoculated sound portions of the tubers with the material of the soft parts, but only the common blue mould has resulted. Destroy all the diseased tubers to prevent its spreading to healthy plants.

LATE CHRYSANTHEMUMS: *J. E. R. N.* If you read the remarks published in the "Market" columns of this journal during the past two months, you will see the names of the best late-flowering Chrysanthemums that have been sent to Covent Garden Market. See also reply in "Answers to Correspondents" in the issue for December 14, p. 424.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

FRUITS: *J. Coombs.* The specimens are insufficiently good for determination.—*Subscriber* The specimen is insufficient; probably a Juniper.

PLANTS: *Ichabod* Epidendrum ciliare.—*Veritas* 1, Plemothallis obovata; 2, Oncidium sphacelatum; 3, Oncidium altissimum. 4, Pteris umbrosa.—*O. H* Reineckia carnea. *W. H. C.* 1, Begonia nitida alba; 2, Begonia subpeltata variety; 1, Codiæum (Croton) Johannis; 2, Codiæum variegatum.—*No Name.* You have omitted to send name and address, and have addressed the flower to the Publisher when you should have addressed it to the Editor The flower is Cypripedium Harrisianum, the light form often called C. Dauthieri.—*F. A.* Angræcum falcatum, a pretty little Japanese Orchid, easily grown in a cool house.

NEW ZEALAND FLAX SEEDS: *Acacia.* If the seeds have germinative power, they should sprout in a heat of 65°, such as you have afforded. Soaking them in warm water for 24 hours before sowing might be useful, and a bottom heat of 75° would likewise hasten their germination. Sow in rich, sandy loam ½ inch deep.

PALM LEAVES WITHERED: *O. H.* There is no doubt that the fumes of the gas in the dwelling-house causes the damage to the plants. It is possible also that the plants have suffered drought at the roots, and this condition would help to increase the mischief.

PEARS FOR NORTH AND EAST WALLS: *G. R.* In Kent and such favoured counties, the great majority of both early and late varieties of Pears succeed either against north or east walls. The fruit is not quite so large in these positions, but the flavour is equal to those grown on west or south walls, especially if left to hang till very late in the autumn. The following varieties are amongst the best for your purpose:—Pitmaston Duchess, Doyenné du Comice, Marie Louise, Beurré d'Amanlis, Beurre Dubuisson, Beurre Hardy, Clapp's Favourite, Conference, Marguerite Marillat, Triomphe de Vienne, Winter Nelis, and Josephine de Malines. Situated as you are in South Devon, you ought to have no difficulty in growing these varieties well, unless the position is one greatly exposed to violent winds. We have found from long experience that fruits upon north and east walls require frequent waterings, owing to the fact that most of the rainfall comes from the south or west during the summer months. This matter is of very great importance.

PELARGONIUM LEAVES: *A. A.* Puncture by aphis in the young stage of the leaf often develops in the manner shown on the specimens received. Remove all the damaged leaves and the plants will probably grow perfectly natural when there is more sunlight.

SITUATION IN AN ERFURT NURSERY: *C. H. H.* Living is not so cheap in Germany as was formerly the case, and we should doubt the statement that board and lodging can be obtained for 7s. per week, except in very low quarters; 10s. is nearer the mark, and you must be content to live like the native. Tea is almost unknown and very dear; pure coffee is dear. The beefsteak or chop of Old England are rarities, but there are compensations. Where other young persons exist you can also live: it is merely a question of getting used to the conditions. A wage of 14 mk. per week will keep you, provided you have no expensive tastes. You should find a residence of a few years in the centre of the seed raising and plant trade of Germany of great use to you as a gardener.

SNOWDROPS: *H. W.* Your bulbs are attacked by the Snowdrop white mould (Botrytis galanthina), see *Gardeners' Chronicle*, May 2, 1889, p. 275, which mould is the prelude and conidia of Sclerotinia Fuckeliana—at least such is supposed to be the case. There is no remedy but to destroy the diseased bulbs so as to prevent the disease from spreading.

SPIRÆA PLANTS: *A. H.* We think the inflorescences have suffered from strong manure water having been spilled over them. You do not state for what purpose the stamps were enclosed.

TRANSPLANTING A ROSE FROM ONE HOUSE TO ANOTHER: *H. Churchman.* Carry out the operation at any time onwards till the beginning of the month of March—not later, or the plant will have begun to grow at the top. Prepare a large hole, and fill this with fresh rich soil, but do not bring the manure into direct touch with the roots. Make the soil firm below and above the roots.

WEYMOUTH PINE "COCCUS" AND INSECT ON BEECH: *Subscriber.* Can you send specimens of each pest? There are several distinct species of insects which attack Beech trees and Conifers.

YEW TWIGS: *A. S. S.* The swollen buds on your Yew trees are due to the attack of a gall-gnat, Cecedomyia Taxi. If you pick off the leaves you will find a very small orange-coloured grub in the centre This is responsible for the malformation, which is very common in Yew trees

A SUSSEX WASTE.

WHEN Scotch planters speak of "waste lands," such as it has been often proposed to plant, they commonly have in mind bleak mountain slopes or poor land worth a merely nominal rent, or morasses of still less value, and when they first see the Sussex and Surrey wastes they get a surprise. In the first case, the land is poor, and has always been poor or "waste"; in the second, it is good land that has been allowed to become waste.

An old writer has declared that, when it was desired to reduce good land to the lowest value, the best plan was to make "common" land of it, and if ever there was a striking example it is to be seen in the twenty thousand acres, more or less, now constituting Ashdown Forest in Sussex, and belonging to anybody. According to local tradition, this common was granted or created in the time of one of the Charles's, but under what conditions I have not learned. Some of the natives are rather proud of their derelict forest, and a ride over the ground in a motorcar is now considered quite a treat for a stranger. Anyone longing for the "simple life" might have all his wishes gratified in some of the desolate spots among the whins. I once walked for miles to get a newspaper and failed. In one village of considerable size there was no newsvendor of any sort. The little post office had none to lend or sell, and the ramshackle little public-house of bricks and timber had none either, and the landlord said he did not think one could be got. St. Kilda is better off.

Sussex, according to agricultural returns, is credited with about 18,000 acres of mountain and heath lands, but Ashdown waste appears to be left out, for, although it is neither mountain nor heath, it is certainly "waste" in the sense in which foresters understand the term. Nevertheless, it is mostly first-class agricultural land, or land of fair quality, in a sunny climate, that under cultivation produces the finest crops of nearly all kinds. During the past and other years, we have seen, on cultivated patches of the forest soil, Wheat and Oats over 6 feet in height with well-filled ears.

Sussex is also credited with over 124,000 acres of woods, by far the greater portion of which is, however, coppice worth nothing or next to nothing, and in consequence it is perhaps one of the poorest timber counties in England. I make this estimate from the large proportion of coppice I have seen in many parts of Sussex, and not from the Ordnance map records, which are almost useless for such purposes.

I have often traversed tracts of the "forest" and been struck with the fact that here, within an hour from Victoria Station, or an hour and a half by motorcar, you are plunged into one of the wildest and most barren natural tracts in Britain, much of which is likely to be converted into a suburb of London before long. Crowborough is at present one of the chief building centres there, and already roads, streets, and sewers on an extensive scale are being laid out as fast as contractors can work, and villadom has already begun. Every day, but more especially at week-ends, the express trains from Victoria are crowded with passengers from London to Crowborough.

What strikes one most is the utter waste and neglect of what is called the "forest" or "common land." Nothing is done to improve it, and local proprietors dare not encroach to mend it. There are local laws, I have been told, which confer ownership on any lord of the manor who will plant the land with timber trees and keep the timber crop up for a certain number of years, but attempts to do this have been frustrated, in a dog-in-the-manger spirit, by the commoners who, I am assured, destroy the plantations as fast as they are formed. The "forest" is mostly covered with furze, bracken, briars, thistles, and weeds, except here and there where a patch of grass exists and where an odd cottager's cow or goats, or a few sheep, find scanty pasturage.

The soil, as has been stated, is either good or of fair quality and grows excellent crops and still better timber, and as a planting area I should think it could hardly be surpassed. The forest is a great resort of tourists and gipsies. The latter were an absolute nuisance not many years ago, and had to be dealt with by the authorities, and there are numbers in and about the forest yet of the real Romany type. In some instances they own the bit of land where their encampment is in order to escape police interference. From the road over the hill from Crowborough to Uckfield, a distance of 12 miles or thereabouts, one gets extensive views of furze, heather, and bracken, with here and there a tree—nothing more. In these days, when so much is said and written about the land for the people, one cannot help thinking that if the Sussex wastes are a sample, the less the people have to do with the land the better, for such a scene of utter neglect it would be difficult to imagine. What the land is like, and what might be accomplished by cultivation or planting, anyone can see by the existing plantations and crops, where there are any. There is one large private estate in the forest, not far from Crowborough, reserved to the owners by some far-back privilege; extensive tracts of this estate have been planted in more recent times with Larch, Spruce, and Douglas Fir, &c., and now form a fine feature in the landscape and show what the land and climate could do in the production of timber. Indeed, Sussex was once the finest timber county in England, and might be again. For their age, I have never seen finer Larch, Douglas Fir, Scotch Fir, and Oak, than in Sussex, but the Douglas will soon overtop all other species in height. Young trees, planted about 12 or 15 years ago on certain estates, are now beginning to overtop other kinds of trees five or six times their age. The Scotch Fir is another good subject. On the roadside between Crowborough and Uckfield there is a strip of Scotch Fir in which the trees, for height, growth, shape, and number on the ground, excel almost anything I have seen at home or abroad, but the strip is dense, the trees standing only a few feet apart.

Another evidence of the productiveness of the soil all over the forest is the condition of trees and garden crops round dwellings. In parts of the forest villas are being dotted down here and there among the furze like shanties in a backwoods settlement, and in such small clearings all kinds of crops seem to do well. The heavy Sussex clay is known to be a fertile soil, its only fault being that it is difficult to work in all weathers.

Less than a hundred years ago, I believe, some of the fairest and most fertile portions of the Lothians in Scotland were much in the same state as the Sussex commons are now, but there were no restrictions against the land being brought under high cultivation, and that has been done almost wholly by long-lease tenants, who reclaimed the land and walled the fields—at their own expense—with the stones ploughed up out of the ground.

"Common lands" may serve some purpose, but when they are out of all proportion to the population and its wants, and derelict into the bargain, they are not called for. Perhaps some of the readers of the *Gardeners' Chronicle* can tell more about Sussex than I can. It is a lovely country to look at from the outside, but primitive and far behind in many ways—far behind in its forestry and not much better in its agriculture. *J. Simpson.*

BEGONIA GLOIRE DE LORRAINE AT BRAMHAM PARK.

BEING in the neighbourhood of Bramham Park recently I took the opportunity of calling upon Mr. Cameron, the gardener. My main object was to see the batch of plants of Begonia Gloire de Lorraine, which I had heard were very good. The house devoted to them is a span-roofed structure, about 24 feet in length by 5 feet in width, with the usual centre and side stages. It was a wintry day, and the familiar sound of the ice-breakers at work a short distance away came through the air. Taking the Begonias as a whole, they certainly were the best batch of plants I have seen. They had been grown from small cuttings and leaves obtained from friends last spring. They were rooted in a small propagating case on one of the side stages in the adjoining stove, care being exercised in keeping the atmosphere as healthy and sweet as was possible. Little difference could be seen betwixt those raised from leaves or cuttings. As soon as they had formed roots they were potted into thumb pots in a light compost of one part well-rotted loam from the limestone formation, one part well-rotted Beech leaves, and one part fine peat with a sprinkling of fine charcoal, the whole being well mixed together. A similar compost was used in the later pottings, except that a rather larger proportion of loam was employed. During the summer the plants were cultivated on the side stages or on suspended shelves in the same house, the central bed in which is filled with a fine, healthy lot of Palms and Crotons in variety. As soon as the flower-buds appeared in the autumn a slight dressing of an artificial manure was occasionally sprinkled on the surface of the soil, which in no case exceeded 8 inches in diameter. Some of the largest plants measured over 3 feet 6 inches across. Suspended from the roof there were about 20 baskets, also filled with healthy plants, which presented masses of flowers. In an adjoining compartment I noticed a very healthy batch of Euphorbia jacquiniæflora. All lovers of old-time gardens will be pleased to hear that the present owners of Bramham, Mr. and the Hon. Mrs. Lane Fox, are gradually and very tastefully developing and adding to the well-known beauty of the grounds, which in their main features are probably unique in this country. They were originally laid out in the reign of Queen Anne. *Yorkshire Gardener.*

NEW OR NOTEWORTHY PLANTS.

*MAHONIA ARGUTA, HUTCHINSON.

SP. NOV.

IN the summer of 1907 Mr. F. W. Moore, the Curator of the Royal Botanic Gardens, Glasnevin, sent to Kew flowering specimens of a Mahonia which had been in cultivation at Glasnevin for over 28 years, but had not flowered previously, and was still undetermined. It now proves to be an undescribed species, closely allied to Mahonia paniculata, Oerst. The origin of the plant is unknown, but its nearest allies are natives of Central America, where they occur at altitudes of from 8,000 to 10,000 feet on the slopes of volcanic mountains in Guatemala and Costa Rica.

The species here described may be easily distinguished from M. paniculata by the narrower, entire, or one to three-toothed leaflets, the prominent reticulation, and the smaller petals. The leaves have five pairs of leaflets, and are shorter than the inflorescence; petioles sulcate, 7 to 8 inches long; leaflets lanceolate or oblong-lanceolate, almost sessile, or very shortly stalked, leathery, 2 to 3½ inches long, terminating in a spinous point, entire, or with one to three spiny teeth, shining on both sides; veins and veinlets conspicuous. Panicles crowded at the apex of the branches, almost erect, lax, 12 to 16 inches long; branches elongated, with three or four lemon-yellow flowers to each, compressed and rigid, up to 1½ inches long. Bracts of the branches and pedicels ovate-lanceolate, one or two lines long, acute. Sepals nine; three external small, elliptic, 1½ lines long, three-nerved; three intermediate and the three interior oblong-elliptic, 3 lines long, 1½ lines broad. Petals six, oblong, bifid at the apex, 2 lines long, 1½ lines broad. Stamens six; filaments 1 line long. Ovary oblong, 1 line long. Berry globose, about 3 lines in diameter.

Dr. F. Fedde, in an excellent monograph of Mahonia†, which he has restored to generic rank, makes the following comparisons between the two genera:—In Berberis, in its restricted sense, the leaves are always simple, and may be either evergreen or deciduous; whereas, in Mahonia they are always imparipinnate and evergreen. The simple leaf of Berberis, however, is articulated at the base in the same way as the terminal leaflet of Mahonia, so that it may be looked upon as a reduced imparipinnate leaf.

The inflorescence of Berberis is situated at the apex of a short-shoot, which arises in the axil of a leaf-thorn‡; whereas that of Mahonia arises from the axil of a scale of the winter bud which terminates a long shoot.

In Berberis the flower usually consists of six sepals in two whorls of three, six petals in two whorls, six stamens in two whorls, and a single pistil.

In B. Wallichiana, D.C., B. empetrifolia, Link, B. aristata, D.C., and B. quindiuensis, A.B.K., the number of calyx whorls varies from three to five.

In Mahonia the flower always consists of nine sepals in three whorls of three, and the petals, stamens, and pistil, as in Berberis.

In regard to their leaves and inflorescence, therefore, Berberis and Mahonia represent two different lines of development, and might, accordingly, be regarded as generically distinct.

Nuttall, when establishing the genus Mahonia§, stated that the petals did not possess the nectariferous glands which were constant in Berberis; but Fedde points out that the glands are present in all the species of Mahonia, although sometimes inconspicuous, and hence easily overlooked.

Again, the tooth-like appendages on the filaments, given as a generic character of Mahonia by Nuttall, are wanting in some of the species of that genus, and they are present in the section Odontostemones of Berberis.

It is evident from the above comparison that there is a fairly good case for segregation, although the only constant differences are the simple and compound leaves on the one hand, and, on the other, the relative positions of the inflorescences on the shoots. *J. Hutchinson, Kew.*

FIG. 36.—PHILADELPHUS GRANDIFLORUS LAXUS.

PHILADELPHUS GRANDIFLORUS VAR. LAXUS.

THE Philadelphus or Mock Oranges as a class are so well known in gardens that it seems almost impossible to suggest anything which is not already well known in regard to them. The object of the present note is, therefore, merely to call attention to a fine form of P. grandiflorus, known under the above name, which possesses characters which render it worthy of the notice of lovers of hardy shrubs. The flowers, which are 2 inches across, are more loosely disposed and are more numerous on the inflorescence, thus displaying their individual beauty much better than those of the type, while they are produced a week to ten days later. The plant is the largest of the genus, and will quickly form a specimen 10 to 12 feet high and as much across. Incidentally the illustration serves to show what a fine effect may be produced by this plant when grown as a single specimen on a lawn, but the flowers being pure white, require the setting of a background of trees in order to be seen to the best advantage. *C. P. Raffill.*

* Mahonia arguta, Hutchinson, sp. nov., affinis M. paniculatæ, Oerst. a qua foliolis angustioribus integris vel dentibus spinosis 1-3 munitis, reticulatione utrinque prominente, petalis minoribus recedit. Folia 5-juga, quam inflorescentia breviora, petiolis sulcatis 17-20 cm. longis; foliola lanceolata vel oblongo-lanceolata, subsessilia vel brevissime petiolulata, coriacea, 5-9 cm. longa, 1-2 cm. lata, spinoso-terminata, integra vel 1-3 spinoso-dentata, utrinque nitida, venis et venulis utrinque conspicuis. Paniculæ ad apicem ramorum congestæ, suberectæ, laxæ, 30-40 cm. longæ, ramulis elongatis 3-4-floris compressis rigidis usque ad 4 cm. longis. Bracteæ ramorum et pedicellorum ovato-lanceolatæ, 2-4 mm. longæ, acutæ. Sepala 3 externa parva, elliptica, 3 mm. longa, 1½ lata; 3 intermedia et 3 interna oblongo-elliptica, 6 mm. longa, 3 mm. lata. Petala 6, oblonga, apice bilobata, 4 mm. longa, 3 mm. lata. Stamina 6, filamentis 2 mm., antheris 1-5 mm. longis. Ovarium oblongum, 2 mm. longum. Bacca globosa, 6 mm. diametro.

† "Engl. Bot. Jahrb.," vol. xxxi. (1902), p. 36.

‡ Fedde states on the authority of Usteri that these short-shoots and leaf-thorns are absent in B. insignis and B. acuminata. An examination of the Kew material proves this to be incorrect; they are present in both, but sometimes wanting in B. insignis.

§ Nuttall, "Gen. N. Amer." (1818), p. 211.

NOTICES OF BOOKS.

* "THE BOOK OF GARDEN PESTS."

THIS, the latest of the books dealing with plant diseases and pests, is especially designed for the cultivator, and we think it admirably fulfils the purpose for which it was written. All people whose business lies with plants ought to be able to recognise and deal with the more commonly occurring pathological troubles that are the inevitable result of intensive cultivation. Every modern gardener, who is worth his salt, aspires to know something more than the mere manual work connected with his profession, and in these days the spread of education has made it a relatively easy matter for anyone who desires knowledge to be put in the way of getting it. Certainly a general acquaintance with the symptoms and immediate causes of disease should form part of the intellectual capital of every cultivator who means to be more than an unskilled labourer, and it is to the intelligent gardener that Mr. Pearson's book will appeal.

It is clearly written, without detailed discussion or technicalities which would be out of place in a small volume, and the subject-matter is well arranged. In a work of this kind, of course, a selection of the more commonly occurring diseases and pests had to be made, and we can congratulate the author on the way in which he has exercised his discretion in this matter. What the gardener wants when he finds a disease is the remedy; he is naturally more interested in the cure than the more purely scientific questions raised in considering the etiology of the evil. He will find a considerable list of remedies given in the early chapters, and their mode of application is fully described. We have noted one or two misprints in the proportions given for making up certain of these; on p. 11, in preparing Lysol, the proportion of this substance to water is given as 508 pints to 22 gallons; probably 5 to 8 pints was what was really intended, as this represents about the correct amount. In the directions for making up Bordeaux mixture, given on p. 24, the requisite amount of copper sulphate is correctly given as 6 lbs., but a few lines further down 84 lbs. is mentioned. But these typographical errors are so apparent that they should hardly prove misleading.

The general subject-matter of the book is arranged according to the classes of plants; thus there is a chapter on "Pests common to many plants," and this is followed by others in which the maladies of tuberous and bulbous plants, miscellaneous plants, fruit trees, vegetables, and so forth, are considered.

The book is well illustrated, and it can be warmly recommended as one which every gardener ought to possess. *J. B. F.*

"THE SWEET PEA ANNUAL, 1908.

THIS is the official organ of the National Sweet Pea Society, and it is a better issue even than that of last year. New features include a catalogue of all known Sweet Peas, a list of inferior varieties, and a series of questions with their answers, as given by experts throughout the country. Some of the answers are not only of slight value, but are not altogether trustworthy. The audits are fully given, but these must always fail to give satisfaction to the seeker after the best things, because in the nature of things the very best of the newer varieties cannot possibly be given justice. That, of course, is a drawback which one expects, but it surely would not be difficult to get a dozen or a score of experts who have opportunities of examining new varieties previous to their being offered to the public to vote on these and to give the result in the Annual. Mr. Hugh Aldersey provides a short and chatty but delightful notice of Sweet Pea enthusiasts. But if one may venture to offer a correction, both Mr. Burpee and he are at fault concerning the dwarf Alyssum maritimum, which originally came from America. Mr. Dicks contributes a short historical note, and Mr. Atlee Burpee, writing from Philadelphia, records his impressions, which are altogether favourable, of what he saw last summer in England and Ireland. Mr. Leak recommends "sheep" netting as supports, and Major Nedwell tells of how he grows Sweet Peas in New South Wales. Mr. Mackereth, of Ulverston, in forcible language recommends the popular vote as the best means of deciding the position of novelties. A warning to growers to beware of "streak" is given by Mr. W. P. Wright, and then Mr. Bathurst, Chudleigh, tells how he produces Gold Medal blooms. There follows a short exposition by Mr. George Gordon on "Principles," and the history of the Reading trials at which 373 "varieties" were subjected to a thorough testing last year, is supplied by Mr. Charles Foster; a short note from Mr. Fox, Wellington, New Zealand, describes Sweet Peas in the Antipodes. The Annual is edited by Mr. Chas. H. Curtis and Mr. Horace J. Wright, and is freely illustrated with portraits and pictures of Sweet Peas, &c. *B.*

TREES AND SHRUBS.

VARIETIES OF MAGNOLIA GRANDIFLORA.

DR. BEDELIAN remarked in *Gardeners' Chronicle* for December 7 last that all the specimens of M. grandiflora are not of the same habit, and he stated that he had discovered diversities in the direction of the leaves, the petals, and the colour of the veins. Of one variety which Dr. Bedelian describes, he failed to find particulars in several botanical works he consulted. I append the following translation from Professor Mouillefert's particulars of about a dozen varieties described in his *Traité des Arbres and Arbrisseaux*. Dr. Bedelian will perhaps find his specimen to belong to one of these:—

"The varieties in cultivation at present are relatively numerous, amongst which are—*M. angustifolia*, narrow leaved; *crispa*, leaves curled and waved; *gallissomensis*, this is the hardiest variety, and that which makes the finest specimen trees; *macrantha*, large flowers, very fine; *majardiensis*, very beautiful flowers; *nannetensis*, double, and very florriferous; *oxoniensis*, *Lodd. Bot. Cat.*, double flowers; *rotundifolia*, round leaves; *salicifolia*, willow leaved (not the species M. salicifolia); *stricta*, branches upright and close; *ferruginosa*, a rusty-leaved variety, little different from the type, except that the tomentum on the under side of the leaves and shoots has the rustiness more abundant." *J. Murison.*

CYTISUS ARDOINII.

ONE of the most exquisite of all the dwarf Cytisuses or Brooms is that called C. Ardoini, a native of the Maritime Alps, which has been in cultivation for about 40 years, and is viewed with ever-increasing favour by those who are acquainted with this beautiful little flower. As a wall-garden plant it is quite at home, and in the rock-garden it is equally beautiful when properly placed, but it must have a dryish and sunny situation if its beauty is to be fully displayed, and in such its growth is more compact, its flowers are more freely borne, and they seem of better colour than elsewhere. Nowhere do I recollect having seen it so fine as in a sunny wall-garden supporting a bank in the garden of Mr. Hope, of Belmont, near Edinburgh, where a plant was thriving and flowering in the most delightful way a summer or two ago. It revived afresh the admiration I have long felt for Ardoine's Broom, with its decumbent stems, hairy leaves, and bright yellow flowers. Its height is only some 4 or 5 inches, and a good plant, such as that at Belmont, is not easily forgotten. *S. Arnott.*

THE ROSARY.

CULTURAL NOTES.

THE east wind has persisted from the last week in December almost without intermission, and the weather in general has increased in severity. The soil is saturated with the heavy rainfall in most parts of the country, and the gardener is wise who takes the precaution to store plenty of litter, Fern fronds, tree leaves, &c., for use in covering his more tender Roses in the present month.

The mild weather in January that prevailed in some parts of this country caused premature growth of Roses planted in sheltered positions, the buds being now almost ready to burst. All autumn and early winter-planted Roses should have their shoots fastened securely against the wind, and the soil made firm about the roots, should this have been rendered loose by frost. I may here make remarks upon the advantages and disadvantages of budded plants on Briar, Manetti stocks and own-root Roses. Many of the less robust varieties thrive better when worked upon thrifty stocks. The Tea-scented on the de la Grifferie stock, and the Hybrid Perpetual on the Briar and Manetti Own-root Roses, when the varieties are of vigorous growth, are excellent; and another point in their favour is that there is an absence of suckers from the wilding stock. The only remedy against the production of root suckers on worked stocks is to carefully disbud the young plants when they are set out, and again when planted out in lines for budding purposes. Gardeners sometimes unknowingly cultivate these suckers, and then express astonishment that they do not flower like the rest of the plant. When the early-forced Roses begin to show their flower buds, use a slight dressing (a teaspoonful) of Clay's fertiliser or canary guano to a 6-inch pot, stirring the surface a little and affording water to carry it to the roots. A dose of the fertiliser may be applied twice a week till the flower buds show colour, when once a week will suffice, and as the flowers develop in size discontinue the manure altogether. Established plants of Hybrid Perpetuals take from eight to ten weeks to force into bloom, and those potted in the autumn from ten to twelve weeks, according to the variety.

Teas and Noisette varieties will take a few weeks less time. As the sun heat increases with the season, less time will be required to bring on the plants. It may be here stated that varieties of the Hybrid Perpetual class are impatient of hard forcing, and if this is practised the quality of the flowers will be poor. A day temperature of 55° to 60° by artificial means is high enough, but with sun-heat it may rise to 65° without injury to the blooms. In order to maintain a succession of blooms several batches of plants should be grown, and these brought on under glass as may be required. Keep the Rose forcing-house humid, and ply the syringe among the plants on bright mornings, but as the plants begin to show flower, less humidity and more ventilation will be necessary, taking care not to admit air when it is very cold. If aphides appear on the plants, fumigate or vaporise them before the flowers open, and for mildew apply a solution of soft soap and black sulphur (*S. vivum*) to the hot water pipes. The earliest grafted Roses will now be sufficiently advanced for repotting out of 60's into 48's (4½ and 5-inch pots). As potting soil, mellow loam of good quality with a small quantity of decayed manure and sand added thereto will suit the Hybrid Perpetuals; and for Teas, Noisettes and Chinas, a small quantity of leaf-mould may be added to the other substances. In potting the plants keep the point of union under the surface of pot firmly. For drainage use a few small bits of bone and charcoal, which will have a wonderful effect on growth later on. These plants may be returned to the forcing house and kept there till the roots have permeated the new

soil, afterwards removing to a cooler house. Repotting can be continued as fast as they become ready for it until the whole of the stock of plants is finished. Their treatment later in the year will be referred to again. The remainder of the pruning of the plants in the borders may now be completed, *i.e.*, assuming that there is a little artificial heat at command for use in frosty weather when the inside temperature is likely to fall below 45°; with sunheat it may rise up to 55° without any disadvantage if a small amount of air be afforded at the top of the house. The Teas, hybrid Teas, and some of the Noisette varieties are the better for being planted out in borders, and a nice effect is produced when standard plants are mixed among them. Among the newer varieties of the hybrid Tea Roses there are many shades of colour from pure white, cream, pink, and crimson, which almost rival the high-coloured Hybrid Perpetuals, and they have a more prolonged flowering period than those. The varieties Maréchal Niel, Niphetos, Allen K. Richardson, Lamarque, &c., are very good as climbing Roses and for covering rafters, &c. In pruning these climbers the old wood should be shortened back, and all the well-ripened rods retained, merely pinching the unripened ends for flowering during the present season. This will induce all the lower and upper buds to break into flowering shoots later. The house may now be closed for several weeks or till such time as the buds begin to swell after the soil has received a thorough soaking of water. The heat may then be increased to 55° during the day and a moist atmosphere maintained, and the amount of air afforded and regulated in some degree in accordance with the prevailing outside conditions. *J. D. G.*

USES OF THE MOTOR IN HORTICULTURE.

(Continued from page 66.)

WHEN the purchase of a steam waggon or an industrial motor of any description is under consideration, every arrangement should be made to "keep the wheels rolling." It is not unusual, around Covent Garden, to see loaded horse vans standing many hours until the sales of the loads are completed. This method may possibly have its advantages, but, from an economical point of view, it would not apply to a steam waggon. A two or three hours' stoppage is within reason; but if it is probable that the delay will frequently exceed this, arrangements should be made by which the waggon may be unloaded, in order that it may be employed on other work. A steam waggon employed on depôt to depôt work, without undue waste of time in loading and unloading, will easily cover 50 miles in the day over average roads, and will carry a load of 5 tons, or if a trailer is used, 7 tons. If two journeys have to be made instead of one, 40 miles in the day is ample, for allowance must be made for the extra time occupied in loading and unloading.

The cost of such work will amount to about £7 per week, made up as follows:—

	£	s.	d.
Depreciation, 20 per cent. ...	2	2	4
Insurance	0	5	0
Driver	1	15	0
Stoker	1	0	0
Oil, grease, light, &c. ...	0	5	0
Water	0	2	0
Repairs	1	0	0
Fuel (coke), 30 cwt.	0	15	6
	£7	4	4

During the first year, provided that a capable driver is engaged, no repairs should be necessary other than the driver will be able to deal with himself. It is better to pay a little extra for a driver with a good all-round knowledge of the machine under this charge, than to engage a man for a small wage who knows little more than how to steer. Where a fleet of several vehicles are to be employed, it is preferable to provide a repair shop and to employ a man whose sole duty it is to maintain the efficiency of the vehicles. In this way the repairs are spread over the whole year, and the engines are always in perfect tune. It is not economical to do this, unless one vehicle is kept as a reserve only, otherwise much of the engineer's time will be wasted.

The manufacturers will give a guarantee with the vehicle, in which they will undertake to make good any breakage due to inferior or faulty materials used. When purchasing the waggon care should be taken in the wording of this guarantee, for that provided by the manufacturer is not of a very binding nature. With these few precautions, at the end of the year the owner will find himself well on the right side of his repair estimate.

Spare parts must be considered, and it is well to have a complete price list from the manufacturer and compare these prices with those for which spares may be purchased from local engineers' stores and such firms who specialise in motor spares of all descriptions. A guarantee should also be obtained with the waggon that all nuts and bolts, studs, steam, and water fittings are of standard sizes and threads.

It is not advisable when repairs become necessary to call in the manufacturer and give him a free hand. If the waggon has been well chosen there should not be much to be done for a year or more except to the bearings, bushes, and, perhaps, a pinion wheel to be renewed. If the driver is worth his money he will be able to do all this with the assistance of his stoker.

To prevent waste of fuel and oil the former should be weighed out in ½-cwt. sacks and booked to the waggon daily.

Oil and waste should be measured out weekly.

It is necessary to have a "permit" to take water from the town mains, but in the country, clean stream water is much better for boiler purposes, and should always be used when obtainable.

Depreciation depends upon the state of efficiency in which the vehicle is maintained. It does not follow that because 20 per cent. is allowed that the life of the engine will only be five years.

For lack of space, it is impossible to give anything but the merest outline of how a vehicle should be maintained, but the above few hints may be of use. The point is not to neglect anything. An adjustment taken in time will save many a breakdown involving great expense.

Never overload a waggon. If it is built for 5 tons, do not put more than 5 tons on it. If a trailer is used, it is better not to use it when the roads are in bad condition, unless it is necessary to carry bulk rather than weight.

If a long delay in unloading is absolutely unavoidable, the small tractor has an advantage over the steam waggon, in that two trailers may be employed; one of these may be left behind for unloading, whilst that which is empty may be returned for another load. In this way the engine need not be delayed. The working expenses of the 5-ton steam tractor are much the same as those for the 5-ton steam waggon. It lacks the handiness of the latter in manipulation, but for certain work it cannot be beaten. In addition to its use as a tractor, it may be used for driving machinery where the belt drive is employed, and will fulfil all the duties of the ordinary portable engine. There is no reason why the steam waggon should not be so employed, but that the engine, in many cases, is not quite so conveniently arranged.

It is hardly possible to give comparative figures of costs, with railway rates varying as they do in every part of the country; but, assuming that the waggon is fully loaded with 5 tons one way only, and for five days per week, the cost works out at 1s. 5d. per loaded mile, including the cost of the empty return journey. This is at a cost of, approximately, 3½d. per ton mile;

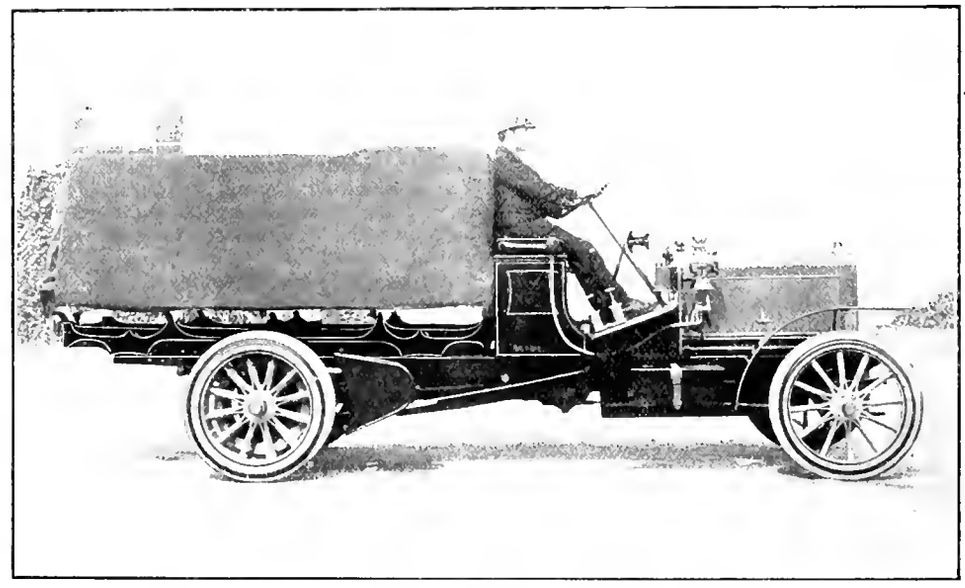

FIG. 37.—THORNYCROFT LORRY, CAPABLE OF CARRYING TWO TONS. PETROLEUM-CONSUMING, FOUR-CYLINDER ENGINE.

but, then, return loads must be taken into consideration, such as manure, coal, and all such stores that are necessary for cultivation. It is fair to assume two-third loads might be obtained for the return journey, and this brings the cost per loaded mile down to 10½d., and the cost per ton mile to a fraction over 2d. Then, the actual cost of marketing 5 tons of produce from 20 to 25 miles distant would be 16s. 8d., or 3s. 4d. per ton. A mathematician is not necessary to prove that this is cheaper than either by rail or horse transport.

There are three points to bear in mind, and these are:—

(1) The best steam waggon obtainable must be purchased.

(2) The best driver obtainable must be engaged and well treated.

(3) The full employment of the waggon must be ensured.

Should the market be 50 miles distant, to arrive at the cost per ton double the above figures, and allow, say, 2s. 6d. for lodgings for the men, and this gives 7s. 2d. per ton.

There are, no doubt, many growers who, not having sufficient haulage work to keep a steam waggon constantly employed, would prefer a

machine which, like the farmer's boy of whom we have all heard, could do "most anything" about the land. Then the agricultural motor is well worthy of consideration; but as the writer is afraid that even now he has approached perilously near to the imaginary line which divides horticulture from agriculture, this subject will not be treated, at any rate for the present.

Hugh Miller, C.E., M.E.

(To be continued.)

VEGETABLES.

EARLY PEAS OF RECENT INTRODUCTION.

DURING the past few years there has been a great advance as regards the quality and size of the earliest varieties of Peas, and though in most instances earliness also is claimed, and there is a gain, there can be no question whatever concerning the two first-named characteristics when we compare the newer varieties which have a Marrow flavour with the small white or green round Peas of former years. Now there is no difficulty whatever in having good early Peas, and

FIG. 38.—"IVEL" MOTORS AT WORK IN A HARVEST FIELD.

these but little inferior as regards flavour to the Marrowfat or summer varieties, but it is only just to add that Marrowfat Peas are less hardy than the older Peas alluded to; and to sow such in a heavy, wet, or clayey soil in October or November is to court failure. At the same time, with some little attention paid to details, this may be avoided; indeed, I have rarely seen satisfactory results from the early autumn sowings in the open ground. The plants have many trials to bear in the shape of rapid changes in the weather, attacks of slugs, snails, and birds. I will therefore note the advantages in frames at the start, whenever cold frames are available; and failing these, note the value of protection in the open ground for a short period of time. This being done, good pods are obtainable at a small outlay in regard to labour and materials.

Frame culture.—There are several modes of cultivating Peas, but I prefer to sow the seeds in pots, in January if possible, and to sow only new seed, the plants from the latter having greater vigour. The pots may be large 60's or small 48's, and if the former, do not crowd the seed; this is a common cause of failure, the seedlings being weak at the start. The soil should be of good quality, and for drainage material use rough siftings of the soil, which enables the subsequent planting-out to be more readily performed. I have also used good-sized pieces of spent hot-bed manure. The soil in the pots should be made firm and not filled-in too much, but plenty of space left for affording water. The pots should then be placed (on a hard bottom so as to keep out worms) in the frames and near the glass, and for a time kept close, to encourage germination of the seeds; in cold weather cover the glass but remove the mats, &c., in fine weather. At the start very little moisture is required, but as soon as the plants are well above the surface ventilate freely whenever the weather permits of this being done.

I have also seen the seed sown on strips of turf and in boxes, troughs, or seed pans, but I prefer pots—the planting out is so readily done; but with plenty of glass at command some of the dwarf growers, which I will presently name, give a splendid return if sown in the frames and grown from the beginning to the finish under glass. Another plan which I have found useful is to sow in 8-inch pots and grow near the glass. Some of the dwarf varieties sown in the month of January will supply pods fit for gathering in April. The new variety Reading Wonder, 12 inches high, is a splendid forcer. Of course, when the plants are intended to be grown in the frames till they form pods a little more space must be afforded, that is, they must be farther from the glass than is needed with pots which are planted out in the early spring. Seed sown to plant out as advised should be ready early in March, and the land should have been prepared some time in advance, and if at all heavy means must have been taken to lighten it. This may be done by a free use of old potting-bench waste soil, and fine burnt refuse or wood ashes are excellent. A rather deep drill is advisable, this being a protection and shelter from wind at the start. The planting should be done firmly, and if possible a south or sloping border should be chosen in the front of a wall for these early crops.

Sowings in the open ground. The same varieties as those advised for sowing in pots should be sown out-of-doors in the south early in February, weather permitting. This crop pays for special attention to cultivation, heavy or wet soil being improved by drainage and by the addition of friable, light materials; these not only benefit the Peas, but the crops of other vegetables that succeed them. I would advise the soil in the trench or drills to be dug out a spade deep, substituting lighter and better soil. There is nothing gained by sowing in wet or frosty weather, as germination is more rapid under better conditions. When sowing, a deep drill should be drawn, and sowings made when the soil is dryish, but no date can be given when to sow, this being dependent on the weather, the season, and the locality. It may be stated that during the last season, seed sown in March produced plants that were in pod in 12 weeks, and these were only protected at the start. With open ground Peas of the Marrowfat type the soil should be friable, and much may be done at the start to assist the crop by using long stable litter, which must be removed in fine weather; by having a deep drill or shallow trench, and by affording the plants support as soon as they come through the soil. It is an easy matter to shake some litter over the rows at night when the weather is cold, drawing the same into the alleys by day. Some gardeners may think that Peas grown in this manner cost too much trouble, but this is not so, and it is well repaid in earliness and good quality at a period when other vegetables are scarce, and the early crops of Peas are worth a little extra attention.

Varieties.—There is a splendid choice of varieties, and one of the first on my list is a new Pea introduced last year—Pioneer, a dwarf plant under 2 feet in height and very robust. It has a dark green pod and is very early, and is excellent for the first crop in the open quarter; seeds sown early in March will be ready towards the middle of the month of May. This indeed is one of the best for an exposed garden that I have ever grown. I have referred to Reading Wonder as a frame or pot variety, and it is a splendid novelty—very dwarf, and its quality excellent for an early Pea; it is equally good for the open ground, and when sown under a wall on a south border, with a wall on the north side, it matures in 12 weeks. Another new Pea that should become a great favourite for cultivating under glass or in the open ground is Sutton's World's Record, which formed a feature at the R.H.S. meeting on May 14 last, and though a taller variety than those noted above, it is a fine forcing variety, a large pod of the true Marrow type, a free bearer, and very early. It is a good variety to sow in pots for planting out, and grown in this way it does not grow so tall, but it affords splendid crops. Another fine Pea is Sutton's Little Marvel, quite different in every respect from the last-named, and it may be called an all-round variety, being equally good for forcing or early cropping in the open; as a proof of its excellence in every point it has received a First-class Certificate, and an Award of Merit from the R.H.S. in a severe test for earliness and quality. For its size Little Marvel is an extraordinary cropping Pea, and is only 12 to 15 inches in height, making it very suitable for small gardens. In my opinion it is greatly superior in every respect to American Wonder or Harbinger.

Another very fine early Pea is Excelsior, a heavy cropper and a fine bearer in poor land. Another remarkably early Pea, and a grand forcing variety, is Carter's Eight Weeks—a suitable name, for when grown in pots it was the first to come into use. It has a good deal of the Marrowfat Pea in its composition, and is greatly superior to the old types of early Peas. One of its parents was William the First, a Pea which years ago proved a great advance upon older varieties. This Eight Weeks variety is 15 inches high, and a splendid early Pea. The Early Morn, a much larger podded Pea than the last-named, is a grand early variety, 3 feet in height, and a rapid grower. It should not be sown very early in warm soils. Carter's Spring Tide is also a very fine early Pea, having dark green pods and possessing the Marrowfat flavour.

It grows from 2 to 3 feet in height. Last season I gave the new Mayflower Pea a trial. It is a cross from Daisy and Wm. Hurst, but it is twice as large as the last-named, very prolific and early, 18 inches in height, and a splendid variety for a warm border. The new Veitch's Langley Gem is another early Pea of fine quality; and the variety Earliest Marrow is excellent for sowing in the month of March. *G. Wythes.*

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

The approaching need for shading.—The sun is often very powerful towards the end of February, if only for a short time in the day, therefore blinds for shading purposes should be made ready for use without delay. For houses which contain species possessing leaves of a soft texture, blinds made of the rather closely-woven white garden net now so freely used, afford the best shading, as they break the force of the sun's rays, but admit plenty of light. A similar material, but of a lighter texture, should be used on houses devoted to such plants as are not injured by slightly modified sunshine. The blinds should, in all cases, be kept well above the glass, as this allows a current of air to pass freely, which serves to keep the atmospheric temperature of the house from becoming excessively hot. They should also be made to take on and off easily, so that they may be stored under cover during winter. Some gardeners leave them in position in order to use them as a covering for the houses on frosty nights, but I fail to see that this practice is advantageous. The covering of the glass is undeniably a good protection from frost, as I previously pointed out, but when the frost is severe, blinds so used sometimes have to be left down until nearly mid-day, owing to the pulleys and ropes being frozen hard, thus shutting out the light that is so necessary for the plants. At the end of winter and during the early spring, when very cold nights are often followed by warm, bright days, the fixed blinds are useful to cover the glass at night, as the frost is seldom severe enough to prevent them from being freely worked early in the next day. It will be a long time before shading will be needed for more than an hour or so during the middle of the day, and it is not advisable to shade the plants sooner than is necessary. The condition of the plants and the position of the houses in which they are growing will determine how soon it is desirable to commence. If the blinds are put into position early this month, they will be ready for any emergency, be it either as a protection on cold nights, or on the bright, cold days which often prevail during this and next month, when it is impossible to open the ventilators to regulate the heat without causing injurious draughts.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

The Muscat of Alexandria and other Muscat varieties of the Grape require a long season of growth and skilful management to bring the fruit to perfection, and the vines which are to furnish the principal crops should be started at this date, in order that they may pass through the critical stages of growth during the seasons most favourable, and the fruit may colour well and ripen perfectly. The leaves of the Muscat of Alexandria if grown in deficiently-ventilated vineries, or in those which have trellises placed too near the glass, are very liable to be "scalded" by bright sunshine; where such defects exist, they should, if possible, be rectified before the vines are started. The vines and houses having been cleansed, and the borders afforded water and a top dressing in the manner previously advised for late vines, the vineries should be closed, and a night temperature of 50°, rising to about 65° from sunheat, should be employed and maintained with regularity, the vines and interior of the vinery being syringed two or three times daily.

Early-fruiting Muscat vines.—The gardener is usually caused anxiety while these vines are in blossom, but if they are healthy the results are invariably good if a night temperature of 70°, with a rise of 5° or 10° on cloudy days, and an increase of 5° to 10° higher on sunny days is afforded, and the air in the vinery is maintained in a dry, warm, buoyant condition, by judicious ventilation. The pollen may then be distributed with a soft brush at mid-day. The disbudding and stopping of lateral shoots should be carried out a few days before the flowers expand, so that no check may occur, and the sunlight is not needlessly reduced in amount whilst the vines are in flower.

Late Peach houses.—The buds on the trees in these houses will soon be developing naturally, and the trees must be prepared for their season of growth, loosening the branches from the trellises and carefully tieing them in bundles. Having done this, clean the woodwork, &c., of the houses, and coat the walls with limewash. The older branches should be thoroughly washed with a warm, moderately strong solution of Gishurst's compound soap, and the young wood with warm soap suds—4 ounces soft soap to the gallon of water. This operation, if properly done, will clear the trees of red spider and brown scale, though these pests are best dealt with in the season of growth. Peach and Nectarine trees that were properly disbudded and had their shoots stopped and trained-in last summer will have a sufficient number of fruitful shoots, which, at 5 inches apart, will furnish the trellises. If there should be an excess of young shoots, remove as many of the more unfruitful and ill-placed ones as is required, clear away the surface soil of the borders, and top dress them with good loam, mixed with plenty of wood ashes and a smaller quantity of bone meal.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

Primulas.—Seeds of P. sinensis, stellata and obconica should now be sown for flowering in the month of November; and shallow pans or 6-inch pots, well-drained, are very suitable in which to sow. The compost employed should consist of equal parts of loam, leaf soil, and sand, the whole being passed through a sieve with ¼-inch meshes, and made moderately firm and quite level on the surface. Before sowing the seeds, the pots should be afforded water, and afterwards covered slightly with a mixture of half loam and sand passed through a very fine sieve, omitting leaf soil for covering as being a cause of damping. Care should be taken in covering the seeds that they are not buried too deeply. Place in a temperature of 60° to 65°, and put a piece of glass on the pans to check evaporation of moisture; and shade the pots, &c., from sunshine. Should the soil need moisture before germination takes place, dip the pots or pans in tepid water until the water appears on the surface of the soil. This is better than applying water with a rose watering-can, as there is then no risk of the surface caking, or of the seeds being washed away.

Begonia seed should also be sown and treated in the same manner as that of Primula, only that after sowing it should not be covered with soil; merely place a piece of glass over the pot or pan and shading from sunshine.

Lobelia and all such very minute seeds are best treated in the same manner.

Seed pots should be examined daily as to the state of the soil, any neglect at this stage meaning partial or total failure. As soon as germination has taken place, the bit of glass should be tilted, more as a prevention of loss from damping off. Strict attention is required to details in raising plants from seeds under glass early in the spring.

Soil.—The repotting of stove plants needs preparation. Fibrous loam and peat of good quality should be chopped into small pieces, the dust shaken out of the peat, and both should be exposed to the air for a few days before the work is begun. Sphagnum-moss should also be picked over, crocks for drainage sifted and placed in sizes ready for use.

Anthurium crystallinum and all the fine-foliaged varieties of Anthurium should now be repotted, using great care in handling them. The most suitable compost for these plants is one consisting of sphagnum-moss one-half, peat one-quarter, and loam one-quarter, with a liberal quantity of wood ashes, charcoal and soft bricks broken to the size of a pigeon's egg. In potting the plants keep the compost well packed up round the collar of the plant, and when new roots appear from this part topdress frequently with sphagnum-moss and a little wood ashes—all Aroids are improved by potash in the soil. Plants that have become unwieldy should be chopped up, and the stem cut up in the manner described for Dracænas, and they should be placed in pure sphagnum-moss till growth takes place. Large plants which are reduced never make fine specimens again, and it is much better to constantly raise young plants.

THE FLOWER GARDEN.

By W. FYLE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Bedding Pelargoniums.—The Pelargonium, if not so popular at the present day as a bedding plant, has but few equals for planting in vases. Where immediate effect is of first importance, the varieties Achievement, Henri Jacoby, Paul Crampel, Madame Crousse, Duke of Edinburgh, and Charles Turner are among the best; plants that are a few years old flower earlier and more freely than one-year-old ones. The ivy-leaved varieties, because of their pendant habit, are suitable for draping vases or window-boxes, planting against walls, or to form pyramidal objects 7 to 8 feet in height in tubs; for this purpose the variety Madame Crousse is unsurpassed. Autumn-struck cuttings should now be potted, according to variety and size, in 4 or 5-inch pots. The ivy-leaved varieties should be furnished with small sticks to which the plants should be fastened as potting proceeds. Do not stop the plants on repotting them. If the stock of plants is insufficient, cuttings should be struck singly in small pots.

Tuberous-rooted Begonias.—Before starting the tubers lay them out at a few inches apart on a layer of leaf-mould, finely sifted peat or silver sand, and put the pans or trays into gentle warmth—55° Fahr.—to induce growth. The single and double-flowered varieties are good as bedding plants, but the single large-flowered sorts are the better ones. Aged plants of fibrous-rooted or shrubby species may now be divided and cuttings taken and struck in heat of 65° to 70° and bottom heat of 80°; and also seeds may be sown. The foliage of these Begonias takes on towards the autumn very beautiful tints, and the flowers are charming.

The rock garden.—Examine the various plants and make firm in the soil any that may have been disturbed by the frosts, remove tree leaves and litter from about the plants, as, if allowed to remain, they may cause the plants to damp off. Mice sometimes cause much injury to rock plants and bulbs, and must be trapped or otherwise destroyed. The position of a rockery, whether exposed and seen from a distance, or placed in a secluded part of the garden, will determine what species of Alpines, &c., are planted on it. If in the former position, and space is ample for planting, groups of plants, say from one to three hundred, in eight or ten distinct colours all flowering at or about the same time. The following varieties may be planted, viz., Aubrietias (single and double-flowered), Arabis, Alyssum saxatile, and A. compactum, Polyanthus, species of Cerastium, Myosotis, and Saxifraga; Pansies, Lunaria biennis, Doronicums in variety, Heuchera sanguinea, with a few "dot" plants such as Helleborus orientalis, &c.

Plants growing on walls.—Although the pruning and thinning will in many instances have been carried out in the autumn, frequent attention may still be necessary in regulating and cleaning some plants, and in reducing the too great accumulation of growth. Take, for example, the beautiful Jasminum nudiflorum, now in fine bloom. It is spoiled by autumn pruning, and sometimes by not being pruned at all, thus allowing of accumulations of annual shoots that assume, as time goes on, a faggot-like form. The proper time to prune this plant is just immediately the flowering season is over. This may consist, in old plants, in the cutting away of much of the older wood, so that the new shoots may develop flowering twigs for the following season. Many varieties of Ivy, more especially the silver and the golden, when planted against walls, are more interesting, and afford a finer effect when the main shoots are laid-in 4 or 5 inches apart, and the leaves considerably reduced in number.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Parsnips.—These require a long season of growth, and seeds should be sown as early as the land is in a suitable condition. Assuming that it has been trenched but not manured during the past six months, the surface soil should be forked over and broken up finely. Land which was occupied with Celery last season is very suitable. Sow the seeds in drills drawn at distances of 18 inches apart. The seed should be placed at regular intervals about as thick again as it is intended for the plants to remain; after this, neatly rake down the ground with a wooden rake. If extra fine specimens are required for exhibition purposes, it will be necessary on many kinds of soil to bore deep holes and fill in with finely-sifted, suitable soil, such as old potting soil that has been stored. Make the holes 20 inches apart, and allow 2 feet between the rows. Press the compost in moderately firm, and place three seeds in each, and afterwards thin the plants to one to each station.

Spinach.—Make a good sowing on a south border in drills 14 inches apart, on ground which has been deeply tilled and well manured. So important is this crop in most households that a small sowing should be made about once a fortnight in various parts of the garden. Splendid early crops may be obtained by sowing now on a very mild hotbed in frames. The Carter and Victoria Round are both splendid varieties for affording early crops.

Autumn-sown Spinach has succeeded remarkably well this year in many places. Take advantage of fine weather and ply the Dutch hoe frequently between the rows, and give a good dusting of soot once a week.

Spring Cabbage.—The earliest plantations of this ought now to be looked over if the weather is favourable. Make good any vacancies and stir the soil with the draw hoe, taking care to pull the finest well up round the stems of the plants. Make a small sowing in a gentle heat of some of the improved quickly-maturing varieties, of which there are many well adapted for spring sowing; also Winningstadt and Blood Red for autumn use.

Celery.—Any time after the first week in the present month the first sowing of Celery seed should be made. Sow the seeds thinly in pots or pans, and raise the plants in a heat of from 55° to 60°. An important point in Celery culture is that any check the plants may receive, especially in their infancy, such as getting very dry or overcrowded, will almost sure to end in a large percentage of them prematurely running to seed. Three of the best varieties that I know for general and exhibition purposes are Invincible White, Aldenham Pink (new), and Standard Bearer, the last-named variety being specially hardy and well adapted for winter and spring use.

Capsicums and Chilies.—Seed of these should be sown at once in a brisk heat. Many of the newer varieties when well grown are not only much appreciated for culinary purposes, but are extremely decorative during the autumn and winter months. Seed should be sown early and the plants grown along without any check. Little Gem, Prince of Wales, Long Red, Long Yellow, and Mammoth are all desirable varieties.

Lettuce, Radishes, Cauliflowers, and Carrots.—Make further sowings of these crops on mild hotbeds.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Strawberries.—The plantations that were planted late last autumn should now be inspected when the ground is not in a sticky condition and the plants made firm in cases where the recent frosts may have lifted any of them out of the soil. It will sometimes happen that autumn planting cannot be carried out, and the work must be done in the spring, and in this event the ground to be planted should have been deeply trenched and afforded a liberal dressing of manure, and early in the winter. Unless forced plants, carefully hardened off, are to be set out in the spring, planting should be deferred till July or August, and the earliest runners secured for the purpose. Potatos or other early crops may in that case be taken. Plants thus set out early will afford a full crop of fine fruits the next year, whereas those planted at this season will not do so, and the chances are that they will be impoverished for the second season.

Plants that have been forced should be set out at a distance of 2 feet and young plants at 1 foot apart in the row, and 2 feet between the rows, every alternate one being chopped out as soon as it is cleared of fruits the first season. After the planting is completed, the ground should be mulched with short stable litter or spent Mushroom-bed materials. After the late heavy downfall of rain and the absence of snow in some parts of the country, old plants will have been injured by recent frosts. It is a general practice with gardeners to examine old plants in the month of October, removing any visible runners and applying a heavy dressing of manure, of which the winter rains carry the manurial properties to the roots of the plants. On heavy soils it is better to apply a lighter mulch or top-dressing such as mulchings from Vine and Peach borders, laying this to the depth of 2 to 3 inches, and leaving it loose and rough on the surface, and in the spring apply a dressing of soot and wood-ashes, raking them in.

Nuts.—These useful additions to the dessert are seldom given the position best adapted for their well-being, and the bushes are pruned very severely or not at all. In gardens they are usually planted in an out-of-the-way place, to hide some unsightly object or as a protection to some tender plants. The chief object in pruning Nut bushes should be to keep the centre of the bush open, thus admitting sunshine, and to cut shoots to the required length. Suckers should be removed with the suckering tool. The condition of the catkins will decide the time when and how the bushes should be pruned. The tiny red female flowers make their appearance in February, and the beginning of March is quite soon enough to prune. If this operation is carried out at an earlier date a good quantity of catkin-bearing twigs should be retained on the main branches. The Kentish Cob and Pearson's Prolific, a round Nut, are two good and reliable varieties to plant. Allow about 12 feet apart between the plants. Rake off as much loose and inert soil from under the old bushes, and replace it with potting-bench soil, or farmyard manure.

PUBLIC PARKS AND GARDENS.

By JAMES WHITTON, Superintendent of the Parks and Open Spaces in the City of Glasgow.

The treatment of playgrounds.—The difficulties attendant on the acquisition of sites having been overcome, the authorities often find some trouble in dealing with what at first sight appears a very trivial matter, namely, how the plot or plots should be laid out. There may be some local feeling on the question, or even divergence of views in the departmental committee. One section may maintain that all that children require, or desire, is a free space whereon they may disport themselves as they please, without any restriction whatever. Another may contend that no playground is complete without some installation of gymnastic appliances, while yet another may want none of these, and, being more sentimental than practical, may ask for flowers and pretty things. As it is the gardening part with which we are mostly concerned, let us look first to the conditions presented in the case of the smaller type of playgrounds, taking for example a situation which is frequently met with in large cities. There happens to be in a crowded area an old building which has been condemned by the health authorities as unfit for human habitation on account of its insanitary condition and, as a hotbed of disease, constituting a menace to the health of the community. Should the area not admit of the erection of modern dwellings with sufficient air space to meet the requirements of the sanitary regulations, then comes the opportunity of the local authorities to secure an open space which, though of limited area, may be very valuable in the locality. These, and occasionally one of the odd spots left when a railway is built through a town, while not by any means ideal, are probably the only places available. It further must be observed that these small places possess relatively more hygienic value in the densely crowded and older parts of our great cities, where the poorest of the industrial classes usually live, than larger areas would have in the more modern quarters. Small plots such as I have described usually have somewhat grimy and squalid surroundings. To attempt gardening in these would, in nine cases out of ten, be courting failure, and defeating a very laudable object, which, however desirable, ought never to be countenanced in obviously impossible situations. The situation and requirements of the district must in all cases govern the plan, and in dealing with playgrounds simplicity of design is the most essential characteristic. The average youngster is a very practical animal, who possesses but little sentiment, and has no sympathy with gardening or any art when it restricts or interferes with his freedom of action.

Question of paving.—Frequently, when dealing with a small area, it will be found wise to pave the entire surface with some smooth impervious material such as cement concrete, tar macadam, or one of the many excellent bituminous asphaltes. This admits of easy cleaning, an important point in dealing with playgrounds in certain areas. Should the space be too small for a set of gymnastic appliances, nothing may be required beyond a few seats fixed firmly into the ground, and a drinking fountain. The quantity of water which youngsters consume is greater than most people imagine, and proper provision for their needs cannot be too strongly insisted upon.

THE APIARY.

By CHLORIS.

Examination of the stocks.—It is not advisable to examine the brood chamber so long as cold weather prevails, and if one is certain that the bees have sufficient stores, it will be prudent to leave them alone at present.

General notes. There may yet be many sharp frosts, and for this reason it is not wise to give any food of a stimulative nature, that is, liquid food (syrup of honey and water), which would break up the cluster of bees, causing them to scatter over the combs, since if a frost came they would be more liable to be chilled, and might probably die. Stimulative feeding causes the queen to commence ovipositing; possibly this has already commenced, but the feeding would cause more brood to be reared than the bees could comfortably cover, and when the cluster of bees contracted in a cold spell all uncovered brood would perish.

Dead bees.—During the present season many bees die naturally and from chill; these should be cleared from the floor-board by raking them through the entrances on fine days, when the operation should be performed as quickly as possible.

Feeding. Generally speaking, when the Crocuses are in bloom we may venture to give the bees Pea Flour as artificial pollen. To induce the bees to store this flour it must be sprinkled on straw or shavings, in a sheltered but sunny place. The bees will continue to carry this to the hives, until the catkins of the Hazel and Palm willow shed their stores. If other food be required, it is best to give a frame of sealed honey, or, if no comb honey be procurable, heat (not boil) some extracted honey, taking care not to burn it, and work into it some granulated or caster sugar, until it reaches the consistency of dough. Then place it in a section over the feed-hole. Should there be no honey, then the candy must be made of sugar and water. Take some granulated sugar and put it into a saucepan with very little water. Let it boil, but stir it well to prevent burning; when it grains (to test this, drop a little into a saucer containing cold water), then take it quickly from the fire, stir until the candy becomes quite white, and ladle out into pieces of paper. By stirring we retain more moisture in the food, and this is required, provided it is not too sticky to handle. Should you burn the food in cooking, no amount of boiling will cause it to candy, and also the food will cause death during the winter weather.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, FEBRUARY 11

Roy. Hort. Soc. Comms. meet. and Annual Meet. of Fellows.
Annual Dinner of Hort. Club.
British Gardeners' Assoc. Ex. Council meet.

FRIDAY, FEBRUARY 14

Roy. Gardeners' Orphan Fund Annual Meet. and Elect. of Candidates.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—39°.

ACTUAL TEMPERATURES:—

LONDON.—*Wednesday, February 5* (6 P.M.): Max. 44°; Min. 35°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London. *Thursday, February 6* (10 A.M.): Bar. 30·6; Temp. 46°; *Weather*—Fair.

PROVINCES.—*Wednesday, February 5* (6 P.M.): Max. 49° North-east coast of Scotland; Min. 42° Peterborough.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—

Sale of Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY AND THURSDAY—

Hardy Plants and Bulbs, Lilies, Azaleas, &c., at 12. 1,000 Roses, at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—

Clearance Sale of the Stock of Seeds, Utensils, and Sundries, *re* A. Legerton, deceased; at 5, Aldgate, London, E.C., by Protheroe & Morris, at 12.

Herbaceous and Border Plants, Hardy Bulbs, Lilies, &c., at 12. 3,600 Roses and Fruit Trees at 1.30. Palms, Azaleas, &c., at 5, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

FRIDAY—

Imported and Established Orchids in variety, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

The Calceolaria.

A correspondent having recently enquired what are the distinctive characteristics of the herbaceous, shrubby and bedding kinds of Calceolarias, Mr. James Douglas has contributed the following information, which will be read with interest:

In a certain garden in Surrey there occurred a curious circumstance two years ago. A patch of seedlings developed on one of the borders, some of them even appeared on the garden path, and, when they flowered, the plant proved to be Calceolaria pinnata, a Peruvian species figured in the second volume of the *Botanical Magazine*. How the plant came there no one knew. Curtis adds: "It is as easily raised from seeds as any plant whatever." Also, "that they will flower, ripen, and scatter their seeds if grown in the open border."

There are over two hundred species of Calceolarias named in the *Index Kewensis*, and many coloured plates scattered over the pages of various periodicals since the *Botanical Magazine* was founded. There are thirty-seven different species figured in the *Botanical Magazine*, and many coloured figures of garden varieties in the *Florist*, *Floricultural Cabinet*, &c. From these much knowledge may be gained of the various types of garden varieties now in cultivation.

As a garden plant, the Calceolaria has been greatly esteemed, and it is valued at the present time. Many of us can remember the time when bedding out tender plants, such as the Pelargoniums, Verbenas, Calceolarias, and other species, were an essential feature of every garden, no garden being complete without its beds and borders of these flowers. The Calceolaria was one of the most important, as no other plant could furnish the same rich golden colour. The species and varieties cultivated for bedding purposes were quite different from those grown for greenhouse decoration. The bedding varieties were usually termed the shrubby section, and those grown specially for the greenhouse and the conservatory the herbaceous. C. rugosa or C. integrifolia, figured in the *Botanical Magazine*, t. 2523, was certainly one of the types grown for bedding out purposes, and doubtless varieties raised from it. It is also figured in the *Botanical Register*, t. 744, and was stated by the editor to have been introduced by the Horticultural Society from Chili or Peru, which is the native habitat of nearly all of the species. The figure was drawn "at the Chiswick establishment belonging to that useful and thriving association," thus wrote Dr. Lindley in 1823. Varieties of C. rugosa, of which integrifolia is merely a synonym, are angustifolia and viscosissima. Most of the garden varieties so largely used for bedding purposes were probably obtained from C. rugosa. Another very distinct species much used for bedding-out purposes was C. amplexicaulis. Mr. William Lobb detected it when collecting for Messrs. Veitch in South America, near Mina, from whence he sent seeds. It was figured in the *Botanical Magazine* in 1847, t. 4300. The flowers were larger than those of C. rugosa and of a softer yellow.

There was a deep crimson-purple variety also grown for bedding some 50 years ago, named Sultan. This could not have developed from any yellow species or varieties; there are, however, two species with purple flowers which may have given rise to this variety. Cultivators found it rather difficult to propagate it in large quantities, nor did it grow with such vigour as the yellow varieties. C. purpurea seems nearest to it as a species, and is figured in *Botanical Magazine*, t. 2775. It flowered first in the Edinburgh Botanical Garden in August, 1827. C. arachnoidea was introduced about the same time and was figured in *Botanical Magazine*, 1828, t. 2874. This species had herbaceous stems, as the variety Sultan also had. The flowers are described as of a dull purple colour.

C. corymbosa is well figured in the *Botanical Register* for the year 1823. This species is often supposed to be the origin of some of the garden varieties. It is described as an annual, and the flowers are of a rich yellow colour. The *Botanical Magazine*, fig. 2418, seems to be quite distinct in colour, brownish instead of bright yellow.

The nearest to the greenhouse herbaceous varieties, so much esteemed for their lasting qualities and rich effect in the greenhouse and conservatory, is C. crenatiflora of the *Botanical Magazine*, t. 3255, or C. pendula of Sweet's *British Flower Garden*, t. 155. It grows a foot and a half high, and was stated in 1833 to be a striking object in the greenhouse. The corolla is yellow, sprinkled with red spots on the lower lip. In this same year—1833—the *Floricultural Cabinet* was founded by Mr. Joseph Harrison, and it is interesting to trace the development of the greenhouse or herbaceous Calceolaria for the next quarter of a century in the coloured plates of that periodical. As far as one may judge from the evidence before us in these illustrated periodicals, I have no hesitation in placing C. crenatiflora as the original type of the spotted greenhouse Calceolarias. I have noted its development for more than 50 years. In the early 'fifties the plants were taller than they are now, and all of them were yellow with the spotting of C. crenatiflora. None of them had taken on the rich blotches we see in the present-day varieties, but one can easily imagine that, in the course of more than half a century, many changes would develop both in the spotting and ground colour. Crossing with such a variety as Sultan, to which I have already referred, would give the rich crimson-tinted varieties. The crenated, elongated pouch was not quite in the style desired by the florists; they worked for a more rounded form, free from crenations, and in the process of selection colour was also developed; therefore arose the beautiful varieties now grown so freely in most gardens. The culture of these varieties is now very simple. There is no need to propagate them by layering or cuttings, as used to be the practice. Splendid varieties can be raised from seed. The seed may be sown as early as April or as late as July. It is very small, and those who have not opened a packet might be surprised at the small pinch contained therein. It is best to have the flower-pot or seed-pan ready to sow the seed before the packet is opened. An inch in depth of fine soil should be made quite level on the top of the ordinary potting compost. Sow the seeds carefully all over the surface, and very lightly cover them with fine soil. A square of glass laid over the top of the seed-pan will cause the moisture to be retained. As soon as the young plants are large enough to be handled, they must be pricked out carefully, and it is in the early stages of the growing plants that care is required to nurse them up to a flowering size. When they are large enough to be potted off singly, they speedily develop into a flowering size. Care is needed to see that they are always moved into larger pots before they become root-bound. Green fly is a terrible pest on these plants, and must be kept off by periodical fumigations. Well-managed plants would become large enough during the season to require pots having a diameter of eight or nine inches.

The bedding or sub-shrubby species are occasionally grown for greenhouse decoration, and there are yet gardens where "bedding out" has not been discontinued; these Calceolarias are invaluable in such schemes, as they afford a rich yellow tint in masses. The path to success is by taking good succulent cuttings as late as the first week in October. They will make roots freely in an ordinary garden frame. The plants must not be coddled in winter, and a few degrees of frost will not injure them. The young plants may be potted off early in the year, or planted out in a pit, to be transferred to the open garden in May.

OUR SUPPLEMENTARY ILLUSTRATION to the present issue represents the form of Moræa iridioides growing in the Botanical Gardens, Durban, Natal. This form was referred to by the Director, Mr. J. MEDLEY WOOD, in the *Gardeners' Chronicle* for July 6, 1907, in a letter sent us in consequence of an article communicated by Mrs. I. L. RICHMOND, May 11, 1907, p. 296, as to the variability of the species, and its remarkable development under cultivation in Ceylon, two forms being illustrated in the issue of the date last mentioned. With reference to the variety now illustrated, Mr. J. MEDLEY WOOD gave the following particulars:—"In 1881, I was living in Inanda, 20 miles from Durban, and about 2,000 feet above sea level. I knew Moræa iridioides quite well, and in that year, or in the previous one, I found what I took to be a new species, the leaves and flower-stems being much longer, the habit different, and the flowers larger and more brightly-coloured. I sent a dried specimen to Kew, and it appears in the *Flora Capensis* as my No. 1,099. In February, 1882, I left Inanda to take charge of these gardens, bringing a plant of the Moræa with me. This plant and seedlings from it have been growing here for more than 25 years; they have had no special attention, and have scarcely been manured. The oldest, if not the original clump, is now 3 to 4 feet in diameter, the leaves and flowering stems are more than 3 feet long and quite erect. During most of the season flowers are borne in abundance, and a dried flower which I have just measured is 4 inches in diameter." The flower is white with yellow markings on the bases of the outer segments, and blue markings in the centre.

ROYAL HORTICULTURAL SOCIETY.—The usual fortnightly meeting on Tuesday next is expected to be a large one on account of the annual meeting of Fellows, which will take place in the afternoon in the lecture room. The Committees have been re-elected or re-constituted since the last meeting, and on Tuesday the new members will be expected to join the respective committees to which they have been appointed. We are informed that Messrs. SUTTON & SONS will exhibit on this occasion the most extensive collection of cultivated Potatos and wild species of Solanum they have ever staged.

GEO. MONRO, LTD., CONCERT COMMITTEE.—We have received a statement of the receipts and expenditure in connection with the eleventh annual concert held on February 21, 1907. The receipts, as distinct from the amount of cash in hand, were £222 10s. 9d. Charitable gifts have been made as follow: To the Gardeners' Royal Benevolent Institution, £12 12s.; Wholesale Fruit and Potato Trades' Benevolent Society, £8 8s.; Surgical Aid Society, £6 6s.; Charing Cross Hospital, £5 5s.; Royal Ophthalmic Hospital, £3 3s.; Covent Garden Lifeboat, £3 3s.; GEO. MONRO, LTD. (Pension Fund), £3 3s., (Outing Fund), £3 3s.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—The members and friends of the Worcester auxiliary held their first annual dinner and musical evening on Saturday last at the Bell Hotel, Worcester. Captain CHECKETTS, a vice-president, presided. Mr. YOUNG, Witley Court Gardens, proposed the toast of "The Institution and its Continued Prosperity," and Mr. W. CRUMP, of Madresfield Court Gardens, responded. Both speakers set forth the claims of the institution, and stated some interesting facts and figures concerning the institution itself and the auxiliary. They pointed out that it is the duty of every gardener, both to himself and to those dependent upon him, to commence early in life as a subscriber of one guinea per annum to the institution. It was suggested that each member should do his best to secure an additional member during the coming year, and one or two names were given in at the meeting. It was highly gratifying to the management to see such vigour and earnestness of purpose as were evident. The honorary secretary gave a short résumé of what took place at the recent election of pensioners in London, which he did in the most lucid and interesting manner. The remainder of the evening was given up to a programme of music.

THE SURVEYORS' INSTITUTION.—At a meeting held on January 21 a paper, entitled "Some Urban Land Problems," was read by Mr. A. W. CRAMPTON. The next ordinary general meeting will be held on Monday, February 10, at 8 p.m., when a paper by Mr. H. COLLEY BRIERLEY and Mr. W. H. CHRISTY CLAY on "The Railway Fires Act, 1905," will be read.

THE LATE SIR THOMAS HANBURY. We are informed that the presentation album prepared by Mr. ALWIN BERGER (Curator of the gardens at La Mortola) for Sir THOMAS HANBURY'S acceptance on his 75th birthday was given to Lady HANBURY at Christmas. The album contains about 160 photographs of the most distinguished botanists and several prominent amateur gardeners, who knew either the late Sir THOMAS HANBURY personally, who had visited La Mortola, or were in communication with his garden. It is a melancholy fact that several contributors, namely, Dr. MASTERS, Sir DIETRICH BRANDIS, Sir MICHAEL FORSTER, Professor MARSHALL WARD, Dr. KUNTZE, and C. B. CLARKE, have died since the album was begun, and that Sir THOMAS HANBURY himself never lived to receive this token of esteem from all over the world. The album contains an illuminated address, the work of Mr. HORNE, Edinburgh, and the binding was executed by Signor GIANINI, of Florence. The cost of the album was raised by subscriptions; it amounted to 1,100 francs. The album will be kept by the HANBURY family as a valued souvenir.

PROTECTING CROPS FROM FROST.—At the Athletic Institute, Birmingham, recently, Mr. WALTER E. COLLINGE, as President of the Birmingham and Midland Counties Gardeners' Association, delivered his address on "The Action of Frost on Plant Life." Mr. COLLINGE stated that we were now rapidly approaching the season of the year when fruit-growers and others stood in great dread of the early spring frosts. Almost every year thousands of pounds worth of fruit and vegetables were ruined owing to the lack of protective measures. As is well known, the atmosphere contains moisture; at a considerable elevation it becomes condensed and forms clouds. If condensation takes place actively and the temperature is above freezing, rain is produced, or snow if the temperature is below freezing. When the moisture close to the earth is condensed at temperatures above freezing, dew is formed; if below freezing, frost is deposited. We may, therefore, define frost as the moisture of the air close to the earth's surface condensed at freezing temperatures upon plants and other bodies. Wherever frost is deposited the plant or other body must possess a freezing temperature. In the case of plants the temperature is reduced by radiation and the evaporation of moisture. Mr. COLLINGE next indicated the conditions under which frost was less likely to do serious damage to plant life. The action and effect of clouds was described at some length, and likened to a blanket over the stratum of lower air. The action of frost on plants is to cause an expulsion of moisture from the cells which form the plant tissues, thus causing drooping of the leaves, as the moisture is not replaced, because the root is chilled. Apart from the advantages to be derived from geographical situation, the grower must depend upon artificial appliances, and very many and varied are these. Screens formed of cloth, laths or glass, covering the plants with straw, smudge fires, and many other devices have been suggested. After examining these different appliances, Mr. COLLINGE stated that, acting on his advice, an Evesham fruit-grower had recently patented a special stove and fuel, which, in his opinion, was far superior to anything yet put forward. It had been tried in Worcestershire, and it was found that 21 stoves per acre were sufficient to fight 9° of frost. One man was sufficient to ignite and look after such fires on 20 acres of orchard. The cost of fuel was about 15s. per acre, and the fires burnt six hours. The inventor claims for these stoves that they not only warm the atmosphere, but that they also give off a good smoke, which acts as a screen, and so protects the fruit from the sun's rays. In the lecturer's opinion, there remained little doubt that ere long British fruit-growers would be as successful as those in the United States in protecting their crops and trees from the late spring frosts, which would mean much to the fruit-growing industry of this country.

PANSY "REV. D. R. WILLIAMSON."—A new Pansy, raised by Messrs. DOBBIE & Co., Rothesay, and named after the Rev. DAVID R. WILLIAMSON, has been awarded five First Class Certificates by the leading Scottish Pansy and Viola societies and the Scottish Horticultural Association. Its colour is deep yellow, heavily blotched with velvety maroon.

ROSES AND THEIR CULTURE.—Under the auspices of the St. Martin's Branch of the Church of England Men's Society, Mr. T. P. ELKINS, Head Gardener at St. Agnes, Knowle, Bristol, recently delivered a lecture on "Roses and their Culture." Dealing first with the historical side of the national emblem, Mr. ELKINS led his audience by easy stages through the different phases of successful Rose culture. He dealt successively with the preparation of the ground, planting, and pruning, illustrating his remarks on the last operation by practical demonstrations on the different varieties which he had specially selected and potted for the purpose. The exhibition of some choice blooms added to the interest of the lecture.

ROSE GARDEN AT BERLIN.—A new public Rose garden is to be created at Britz, a few miles from Berlin, and it will be the largest garden of its kind in the world. It will not only prove attractive during the flowering season, but it will also serve as a means of instruction both for the amateur and the professional Rose-grower.

A NEW CHRYSANTHEMUM JOURNAL.—We have just received the first number of a new monthly publication devoted solely to the Chrysanthemum. It is entitled *La Revue Chrysanthémiste*. Like the one that has already been in existence for the past 12 years (*La Chrysanthème*), it is the official organ of a special society whose headquarters are at 28, Rue Baudin, Paris. The newcomer is very similar in form and style. Its contents include a biographical sketch of M. GOMOT, the honorary president of the Association Française des Amateurs et Jardiniers Chrysanthémistes; and articles on "Our Programme," "The Chrysanthemum in Japan," "Chrysanthemums for Amateurs," "Culture of the Large-flowered Chrysanthemum," rules of the society, and other matter. It is printed in French. Full particulars can be obtained of M. JEAN BIETTON at the address above given.

THE FORMOSA PLUM.—This Plum is one of Mr. BURBANK'S innovations, and is said by Mr. G. C. ROEDING, writing in *The Rural Californian* for January last, to be the best Plum in existence at the present time. The trees are wonderful growers, very free bearers, and are unequalled for quality, except perhaps by the Santa Rosa, which was introduced last year. It thrives over wide geographical areas, and as the habit is rather sprawling, it may require rather severe pruning when young.

POMOLOGICAL INSTITUTE AT PROSKUROFF.—During the current year various courses of lectures and practical instruction are to be given in forestry, horticulture, and fruit tree management at the Royal Pomological Institute at Proskuroff. The Minister of Agriculture, by an ordinance of December 7, 1907, has opened the courses to women, who are also to be admitted to the regular two-years' course of the institute.

AMERICAN NOTES.

THE ROSE SOCIETY.

EVERYTHING points to a very successful meeting of the American Rose Society in Chicago in March. Raisers and growers are stimulated by the excellent prizes offered by Mr. Philip Breitmeyer, of Detroit, and Mr. A. T. Boddington, of New York, $200 first, and $100 second, for not fewer than 50 varieties or 150 plants of Roses suitable for outdoor culture, to be shown in pots or tubs. The fight for the honour of holding the "Dorrance" shield for a year will also be keen; this is a handsome trophy, and the names of succeeding winners are to be engraved upon it. Other prizes of value for artistic grouping of Roses and for American-raised varieties will ensure a large attendance of growers.

CARNATION BEACON.

Some of the largest growers are discarding other scarlet varieties for Beacon, and the popular Robert Craig and Victory are in many cases being thrown out this season to make room for it. Beacon is probably the largest producer of fine flowers, and the quality and colour of the blooms are excellent. It flowers early in September, and continues late. The worst fault urged against it is its somewhat free production of growth shoots, rendering wide planting necessary. But when such large quantities of fine flowers are produced this ceases to be a fault, such growth ensuring a correspondingly free root action that makes comparatively heavy feeding possible.

CARNATION WINSOR.

Growers who may feel inclined to throw out this fine variety through want of success should first be sure they are treating it correctly. Outdoor culture in summer is not suitable, and the best plants are they that have been grown entirely under glass. Its lively colouring and erect stems, combined with a perfect habit and the quality of free flowering, bring it into the front rank of pink varieties, even though its flowers are not of the largest size. Benches here with 3,500 plants on each, and every one carrying from two to three flowers, with many buds to follow, are certainly a fine sight. It is one of the most refined flowers in the whole range of market Carnations. *Correspondent.*

BRITISH GARDENERS' ASSOCIATION CERTIFICATE.

At fig. 40 we have reproduced the design which has been selected by the Executive Council of the British Gardeners' Association for presentation to its members as a Certificate of membership. The design has been chosen from a large number of various kinds, and appears very suitable for the purpose for which it is intended.

SPIRÆA CANESCENS.

FOR giving a pleasing display of flowers during early June, this species is one of the most desirable of the shrubby Spiræas, but at present is not met with to any extent in gardens. It forms a neat, compact, twiggy shrub, 3 to 6 feet high, with arching branches covered in the upper parts and on the under sides of the leaves with softly tomentose or pubescent hairs. It is a native of the temperate Himalaya from Kashmir to Kumaon, and in Sikkim at altitudes of from 6,000 to 12,000 feet. The flowers are ¼ inch in diameter, pure white in the forms which are at present in cultivation, but pink varieties are recorded from its native habitat. They are clustered together in short, lateral, compound corymbs on the ripened shoots of the previous year, the inflorescences all turning upwards in the form of a long spray. The leaves are simple, shortly petiolate, and vary considerably, both in size and shape, on a single shoot, being mostly obovate, ovate, or elliptic-ovate in shape, entire or toothed, and from ½

FIG. 39.—PENDULOUS SPRAY OF SPIRÆA CANESCENS.

to 1 inch in length, and ¼ to ¾ inch in diameter. It is a near ally of both S. hypericifolia and S. arcuata, and has been known under the name of S. canescens. *C. P. Raffill.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

WHAT IS AN HERBACEOUS PLANT? The correspondence now going on in your columns reminds me of a difficulty experienced at a horticultural exhibiton in this county last year. The schedule offered a prize for 12 hardy perennials. The exhibit we judges decided to be the best had one bunch of Gladiolus Rosy Gem. With the consent of some of the committee, we decided to put on the exhibit, "Not according to Schedule," all parties agreeing to a referee whose decision was to be final. The decision was against us. My colleague was Mr. Leadbetter, Tranby Croft Gardens, Hull. Will you kindly give your opinion? *Yorkshire Gardener.* [The Gladiolus was clearly according to the Schedule, as it certainly falls within the definition of a hardy perennial.—ED.]

———Being responsible for the opening of the discussion on this subject, I am naturally interested in the several views advanced by correspondents. The result proves a great want of unanimity in ideas, hardly any two agreeing upon any portion of the argument. How difficult, then, must the framing of classes be for committees, and how peculiar is the situation of judges where the conditions lack plainness. I have known several societies dispense with the word herbaceous entirely, owing to a want of agreement in committee, and so frame their class that it should read thus: "Twelve varieties of hardy flowers." Such conditions are, however, not at all satisfactory, as so much variety can be introduced, such as Roses, shrubs, &c. Just to illustrate how difficult committees of even important societies find the wording of the class, I will quote from a few of what are termed leading prizes schedules:—*Shrewsbury.*—"Collection of hardy perennials (Roses excluded); first prize, £10." *Cardiff.*—"Collection of hardy flowers, distinct varieties, excluding annuals, biennials, shrubby plants, and trees." *Royal Caledonian Society.*—"Twelve bunches hardy herbaceous perennials." *Brighton.*—"Collection of hardy perennial and bulbous flowers." *Grand Yorkshire Gala.*—"Collection of hardy cut flowers"; another class—"Twenty-four bunches hardy border flowers." Thus it will be seen how difficult it is for a new society to follow what are termed leading societies, as all appear to frame their classes to suit their own taste, convenience, and locality. I have come to the conclusion that those who wish to encourage strictly herbaceous perennials would do well to insert a footnote as to their ideas. Personally, I consider a true herbaceous perennial is one which dies down annually, making its growth, flowering, and passing away, like a Lychnis, Phlox, Lilium, Montbretia, &c. *E. Molyneux.*

———If no reasonably good general term can be found to meet the case, the only alternative is to educate those whom the matter concerns up to the true meaning of that old, long-standing term "Hardy herbaceous." This phrase of two words is from the technical standpoint ample enough, broad, full of meaning, and allows great latitude for the rapidly-increasing number of hardy plants. The chief stumbling block appears when we endeavour to restrict the full and true meaning of the phrase itself, and by our own misconceptions of its exceeding comprehensiveness, to endeavour to read into it a meaning which it does not contain, and probably could not, in the presence of any authoritative body, be upheld as correct. The chief weakness in this direction is the somewhat general desire on the part of a large number to argue that a plant with an above-ground growth of a more or less perennial evergreen character is not "herbaceous." Nothing, however, could be more opposed to the actual facts of the case. May I repeat the full meaning of the word "herbaceous"? It is this: "A plant producing annual flowering stems from a perennial root-stock." Here there are two conditions of qualification—the "annual flowering stems," the "perennial root." In these primary conditions nothing is said—and was probably never intended to be said—about either the "evergreen" above ground character of the plants, or their "deciduous" character. The wording does, however, say something about the "flowering stems," and these must be of "annual" duration only. No one, I take it, acting as a judge would attempt to disqualify Campanula pyramidalis—the Chimney Campanula—if shown as one among a number of herbaceous plants in any competitive group of these plants, but the same judge may, and probably would, take exception to an Aubrietia, for example, and consider himself justified in so doing. But such action would be wrong, and both of these subjects are "herbaceous" in the truest and broadest meaning of the word. Is not the 2-inch high peduncle of the Aubrietia

as much the "annual flowering stem" of that tribe as the 6-feet high stem of the Chimney Campanula is of that particular species? Quite so! Both of the subjects named are possessed of an evergreen leaf-tuft above ground, differing in general character and appearance, and, of course, widely so in stature. But the fact that in both instances the flowering stems are annual and perish as the result of flowering each year, coupled with the "perennial root-stock," brings them unmistakably within the folds of "hardy herbaceous plants." It is quite possible that usage and a freer use of those taller subjects suited to exhibition work has been in some degree responsible for a general misconception of the term, those dwarfer subjects which, like the Aubrietia, are not so serviceable in the cut state, being disregarded. To show how widespread is the misconception of the term without meeting with objection. The Royal Botanic Society regularly requested a given number of "stove herbaceous" and "hardy herbaceous," and no other two words of my acquaintance can so adequately contain all that is necessary or desirable. The words "hardy herbaceous" may therefore control the case, and used alone may be taken to imply that the smallest Alpine, bulbous, or other plant could be shown, provided it conformed to those two words in their fullest and broadest sense. Beyond such a limit, it is for schedule-makers and flower show committees to state clearly their requirements, qualifying, if need be, their words by such remarks as "bulbous and tuberous-rooted plants excluded," or the like. Plants such as Romneya, Lupinus arboreus—a specific name of doubtful veracity in this case—and Phygelius, may possibly always be productive of

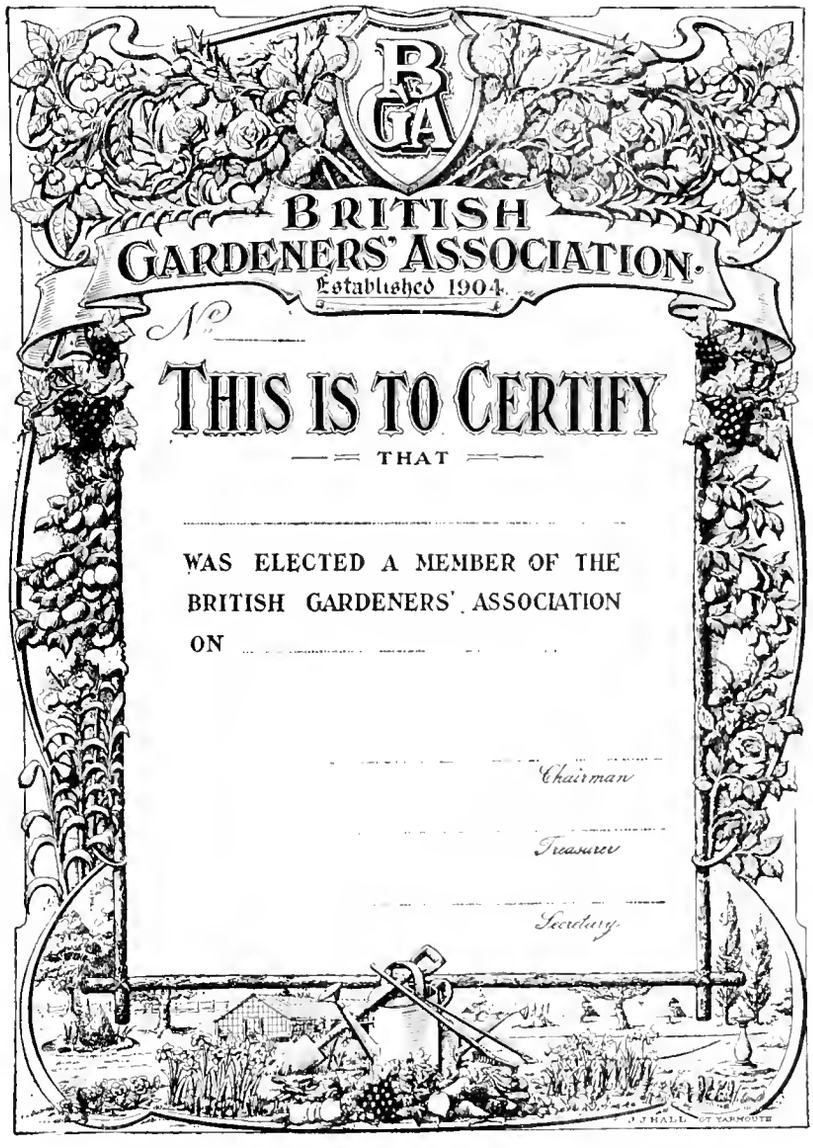

FIG. 40.—A CERTIFICATE OF MEMBERSHIP.

"herbaceous," I may remark that a year or more ago I was approached by a gentleman who prepares students for the Royal Horticultural Society's examinations with the enquiry whether the Megasea—a sectional group of Saxifraga—was "herbaceous." I replied, "Most certainly it was!" The name had been included by a class of students, I believe, but was disallowed by the examiners. Now, if such a thing be possible in high places, it is small wonder that confusion is rife in other directions; indeed, it is a wonder it is not more rampant. No plant could possibly better comply with the "annual flowering stems," &c., than the Megasea, and for years one or more species of these plants were regularly included by the late Mr. Robert Parker, of Tooting, in that gentleman's exhibits of herbaceous plants in open competition debate. These and like subjects appear to provide the links in the chain between true herbaceous plants and true shrubs. The Pentstemon, like Phlox suffruticosa and its forms, are of a different type and must be placed with the herbaceous plants. Naturally, environment has much to do with certain plants, and in particular the shortness or longevity of their existence. Thus, for example, the Wallflower or the Snapdragon may be a perfectly enduring perennial on a wall-top, lasting many years, and at 6 feet or 8 feet lower down—in the same garden, that is—nothing more than a hardy annual, or even a half-hardy one. To many of us, too, our knowledge of the plants we cultivate is limited to our experiences of them in this country, and it is here, of course, that they appeal to us most strongly. In their native habitats they may be different, also by environment. To the closing editorial enquiry at page 40: "But surely the Canterbury Bell is to be regarded as an herbaceous subject?" I can only say, "No, most certainly not!" Inasmuch as its admitted "biennial" character at once excludes it from the rank of "herbaceous" plants, the great essential of which is that they *must* possess a "perennial" root-stock. Thus it is that the brief phrase "hardy herbaceous" contains all that is requisite, if it be but rightly applied. *E. H. Jenkins, Hampton Hill.*

———Is there any better way of wording a class in a competition purposed to include all those plants commonly described as "hardy herbaceous" than is adopted by the Shrewsbury schedule, in which there are two classes, one for 18 bunches and one for 12 bunches of hardy flowers, annuals and shrubs excluded? Certainly such wording opens the door wide enough to admit not only perennials and biennials, but also those perennials which are evergreen and those which are deciduous. Still further, bulbous-rooted plants are not excluded, and what as hardy border flowers are more beautiful than Lilies? In a preceding class the word "herbaceous" occurs, and is there used in the common or stereotyped sense, as it is specifically applied to that section by perennial Phlox, commonly termed "herbaceous." There is still further another class for hardy perennials, from which Roses are excluded. Here, excluding also annuals and biennials, with the Roses, practically everything else hardy and producing flower is admissible. How much better are classes of wide inclusion than those of severe limitation? *D.*

POINTING EXHIBITION VEGETABLES.—Reverting to this subject, point judging can be applied only to collections in which the numbers of dishes range from six upwards, and the rule to point may be enforced, first to compel judges to compare each kind in the collections in a competition, and thus arrive at just conclusions; and secondly, to furnish to losing or purposing competitors, or to visitors, lessons as to which exhibits judges hold to be the most perfect. That is a matter on which the judges who award the points, and the losing competitors, seldom agree; but visitors, being impartial, prefer to regard the judges' decisions as correct, because made by experienced and impartial men. Now, whether the schedule requires an exhibit in any class for a collection of vegetables to consist of six kinds or more, it is obvious that to the judges each dish, being one item in a collection, is as important as another; and moreover, provided that the required number is presented, this makes the collection in accordance with the schedule. But to the exhibitor, that general equality in kinds may not so present itself. He has had to grow his material, and knows which are easy to produce and which are difficult, hence he says that the equality referred to does not really exist. He would therefore urge that vegetables difficult to grow should be given higher appreciation in points than those that are easy to produce. But there are still others who estimate the value of vegetables on the exhibition table by their edible value in the kitchen, and these prefer to give the highest number of points to the kinds they consider to be most valuable. This former appreciation practically forms the basis of the point awards found in the Royal Horticultural Society's code of judging rules; a code which, so far as vegetables are concerned, was arranged with the sanction and approval of a large assemblage of vegetable exhibitors. However, it does not by any means follow that this code is incapable of revision, especially in the light of wider knowledge thrown upon it by some 10 years or more of subsequent experience. The scale of vegetable pointing to which I have referred has been adopted at some provincial exhibitions. At Shrewsbury last year, in connection with that society's splendid challenge or champion class, and where at present the finest vegetable competitions are seen, pointing of the exhibits in that class was enforced. The committee took what I have described as the

judges' view of the equality of kinds, and made all dishes dependent on a maximum of seven points. Hence Potatos and Tomatos, possibly two of the most easily grown dishes, were put on an equality with Leeks and Celery—both very difficult to grow well, especially in August; and Runner Beans and Peas on the same footing as Carrots and Onions, both the latter again being very difficult to obtain in first-class condition. Were this view of the exhibition value of vegetables adopted, taking a collection of, say, 12 kinds, the maximum seven points would be Celery, Leeks, Carrots and Onions; Peas, Runner Beans, Potatos, Tomatos, Cauliflowers and Cucumbers six, and Beets and Marrows five each. It may be pleaded for Cucumbers that as they can be produced only in heat, good, clean, handsome fruits merit the higher number of marks. I think, however, on account of the much smaller edible value of the fruits as compared with others named, few competitors will ask a higher position for them. I should like to elicit kindly criticisms of what I have here written by experienced exhibitors, that something definite and satisfactory to all may result. *A. D.*

NURSERY EMPLOYÉS UNION.—About six months ago a number of nursery hands out Enfield way decided to form a union of "bona fide nursery employes." Their declared policy was to work, if possible, in friendly co-operation with employers, and their stated objects were to raise and regulate wages; to obtain time and a quarter pay for all overtime; the cessation of work at 1 o'clock on Saturdays; to obtain redress for harsh or unfair treatment; to assist out-of-work members, and to co-operate with other bodies of workmen with similar aims. Generally, the union is to be run on the recognised trade-union lines. This obtains for them the support of local trade-union societies and the sympathy of the Labour Party in the House of Commons. They have now four branches. Before the union was formed only one employer in the district allowed Saturday afternoons, whereas now there are 22. The rates of pay for ordinary hands in the market gardens and nurseries in the Enfield district are from 16s. to 19s. per week; the union prescribes 27s. per week of 59 hours for men with two years' experience, that is, competent nursery hands, and a minimum of 20s. for improvers and women. These are rates which, when compared with the trade-union rates of pay for labourers in the district, are not unreasonable. At the last general meeting of the Nursery Employes Union it was decided to extend the scope of the movement so as to admit gardeners and horticultural workers of all descriptions, the title was, therefore, altered to that of "The Nursery and Horticultural Workers' Union." This ought to satisfy those ardent members of the British Gardeners' Association who have advocated a more progressive attitude on the part of that body than it has hitherto shown. The movement for the amelioration of the lot of the gardener, more especially the young or journeyman gardener, will henceforth obtain through this Union the powerful aid of the great trade-unions and the representatives of workers in the House of Commons, as well as that of such enlightened employers as the noble president of the British Gardeners' Association and of head gardeners generally. *W. W.*

BRASSICA CROSSES.—The experiments with Brassicas made by Mr. Arthur Sutton, and recounted in your issue of January 25, are of much interest. I have worked a good deal along similar lines. In 1901 I crossed a number of the derivatives of Brassica oleracea together in various ways. The only hybrid perpetuated was one which seemed likely to be of economic value, viz., Brussels Sprout × Savoy, the plants being short-stemmed Brussels Sprouts with good Savoy heads (see fig. 41). The plants of the second generation consisted of types reminiscent of almost all varieties of the Cabbage tribe, from plants which the casual beholder would call a common Cabbage, through nondescripts of all sorts, sizes and tints, to what could well be described as Curled Kale. Some were obviously similar to Mr. Sutton's curled Thousand-headed Kale. I failed to find Mendelian segregation at work in the series. Plants which repeated the original hybrid form were chosen for seeding. Their progeny varied greatly, but less so than the foregoing. Many plants were identical with Mr. Sutton's Cabbage with sprouts. The photograph of one of them (enclosed) shows, however, that the "Cabbage" contains sprouts squeezed and hidden in its mass. I am not very sanguine of the early fixation of this type as a commercial vegetable. Deliberate crosses attempted in 1901 between Swede and Turnips and members of the Cabbage tribe resulted in failure. I have had no opportunity of noting whether Cabbages can be fertilised naturally by pollen from Turnips, but I have ample evidence that the inverse process may take place, one of my sets of hybrid Turnips having produced plants which are clearly the outcome of an accidental cross with Curled Kale. Reference may be made in this connection to the cross I effected between Curled Kale and Charlock (see report of conference on genetics, p. 202). My reciprocal crosses between yellow-fleshed Swedes and ordinary Rape were fertile. The progeny showed no conformity to Mendelian ratios. The Swede and the Rape may safely be held to be derived from the same parent species. I have not found it difficult to cross yellow-fleshed Swedes with yellow-fleshed and white-fleshed Turnips. The results, however, show that the Swedes and Turnips in ordinary cultivation are certainly of quite distinct origin. The progeny of the crosses between them are for the most part a graded series of rather unhealthy mongrels, oblivious to simple statistical methods of variation. Nevertheless I have just planted many good bulbs of the second generation, representing several

FIG. 41.—CROSS BETWEEN A BRUSSELS SPROUT AND SAVOY OBTAINED BY DR. WILSON.

crosses between Swedes and Turnips, in the full expectation of evolving some useful varieties. The problems to be solved in crossing the derivatives of such a plant as Brassica oleracea are extremely intricate. A good deal of history has been made since the wild Cabbage was first taken from its lonely sea cliff and planted in a garden. Are all the members of its brood the outcome of artificial selection, or has sporting (to use the word most familiar to gardeners) occurred? If mutation has not taken place, can that be shown to be the reason why such a cross as that between the Brussels Sprout and the Savoy leads to the reappearance of a multitude of forms, some of which were perhaps last seen in cultivation centuries ago? Is not the consideration of the habit of self-pollination seen in Peas and our cereals, contrasted with that of cross-pollination seen in Cabbages and Turnips, a profitable line of enquiry to follow with the object of reaching an explanation of the hereditary peculiarities of the plants in question? In course of time tabulation of plants found to exhibit clearly Mendelian segregation may reveal some trait in common explanatory of the processes involved. Neither Cabbages nor Turnips lend themselves to simple demonstration of Mendelian principles. *John H. Wilson, D.Sc., Agricultural Department, St. Andrew's University.*

LUCULIAS.—Having cultivated L. gratissima for the past 10 years, I find that the best place for a young plant is a greenhouse or conservatory border, where the roots will have plenty of room, or if pots are used, they should be several sizes larger than those the plants have previously occupied. It has this peculiarity: unlike the majority of other pot plants, one may over-pot the Luculia with advantage, but to confine it to a small pot and allow it to become potbound is to court failure. The situation of the border should be light and open, and the soil must be well drained, for, although this species is evergreen, it passes through a period of rest, when an excess of water would be very harmful; the soil may be made up of equal parts fibrous peat and turfy loam, with plenty of coarse silver sand, and the soil pressed firmly about the roots. I have both L. gratissima and L. pinceana in the border of a conservatory having a three-quarter span roof. The plants are trained on wires 6 inches from the wall. L. pinceana bears white flowers, and is not such a robust grower as L. gratissima, but for all that it makes a good companion to this species. A winter temperature of from 45° to 55° suits them well. My method of propagating these is to take cuttings in the usual way from well-ripened shoots in June. They are then inserted round the sides of 60 size pots, in a compost of sandy peat. The pots are placed in a cold frame, and covered with a bell-glass, keeping the same closed and shaded from the sun for a time. The cuttings are sprayed occasionally, and they do not require any water until rooted. When they show signs of rooting, air may be gradually admitted, and later the plants may be potted into single pots, using the same compost as for an established plant. The two points to remember are ample drainage and ample pot room. I lost many a young plant before I discovered this. *Thos. Francis, 31, Turton Road, Bromley Cross, near Bolton, Lancs.*

THE NATURE OF SPORTS.—Undoubtedly one of the most baffling branches of biological research is that relating to those sudden departures from the beaten track which result in the production of sports, whether animal or vegetable. Although many theories have been put forward to account for them, so far not the slightest real light has been thrown upon the subject, nor has the least clue been obtained as to the laws which determine their appearance. All that is known is that from time to time a recognised specific form, or it may be a varietal form due already to a sudden sport or by cultural selection of small gradations, assumes, through bud or seed or spore, a fresh and hitherto unknown type. As a rule, too, it is found that the influence, whatever it may be, which has determined the change, is so pervasive in the organisation of the novelty, that its offspring inherits the peculiarity and transmits it to the subsequent generations. In this respect the altered race assumes all the function and qualifications of a new species, though retaining the generic characters as regards floral type or mode of reproduction. Thus, to take the case of the Cabbage family, the versatility of which was recently so ably demonstrated by Mr. A. W. Sutton before the Linnean Society (see *Gardeners' Chronicle*, January 25, pp. 58-59), by means of lantern slides. Despite the marvellous forms which the Brassicas have assumed by sporting and selection, varying from the hard, compressed, ball-like masses of foliage of the Savoy and Drumhead Cabbages, to the feathery, fern-like foliage of some of the Kales, while the normally simple lax inflorescence has been transformed into similar ball-like masses in Cauliflower and Broccoli; and in still another direction, the simple stem has swollen, also ball-like, into the Turnip shape of Kohl Rabi—yet, despite all these metamorphoses, the individual cross-shaped flower of the Cruciferæ always remains true to the generic type with comparatively small variations in size and tint. The Kohl Rabi, too, despite its Turnip-like bulb, distinguishes itself markedly from the Turnip or Swede by bearing on its sides the large scars left by detached leaves, showing that after all it is only a modified swollen stem and not a corm proper, from the summit of which alone the foliage springs. Sports originate in various ways. Seeds or spores may be sown from an apparently quite normal plant or a well-established variety, and among the offspring

there may be one or several, or even many, of a new type possessing the constant reproductive faculty already mentioned. But on the other hand, the sport may make its appearance as a local differentiation on the parent, either as an abnormal, i.e., sportive bud, or, as a slight modification of the reproductive organs, such as a petaloid stamen, which the keen-sighted, selective cultivator notes and profits by as an indication of the "break," which is often the starting point of a new breed. The Fern Gymnogramme Lanchiana grandiceps was raised as a large batch from a heap of spores on a dilated pinnule of the normal uncrested form, and it is conceivable that many other sports originated in a similar way, i.e., by a subtle local modification of reproductive cells. What it is that induces such modification is the biologist's puzzle. Far too many "sports" have originated under wild and uncultivated conditions to admit of the idea that cultivation and high-feeding are the inducing factors. Even if it were proved, which is by no means the case, that more sports were produced under culture than under wild conditions, this argument would be invalidated by the facts that sports in plants under culture are little likely to escape notice, while wild sports are only found by diligent search under quite other conditions. As wild plants they are mingled with many other kinds of plants, while under cultivated conditions the same sorts are grown together and detection of a difference is consequently an easy matter. Cultivation may indeed enhance size and volume, but unless a definite sport occurs the normal habit remains innate, and cultivation being withdrawn, reversion to the wild type inevitably follows. Not so with the sport, and that is the essential difference. As against cultivation inducing a sportive tendency, it is a recognised fact among Fern hunters that "sports" are less likely to be found among Ferns of luxuriant growth than under conditions where growth is somewhat checked. It must, however, be borne in mind in this connection that "sports" vary in all directions, so that many are unfitted to hold their own if handicapped by more robust neighbours, and such have consequently a better chance of survival, as well as of discovery, if they originate outside the crowd, so to speak. *Chas. T. Druery, V.M.H., F.L.S.*

SOCIETIES.

ROYAL HORTICULTURAL.

THE "Book of Arrangements" for the year 1908 has been issued to the Fellows. It contains particulars of the fortnightly meetings, lectures, and shows, lists of the members of the various committees, particulars of the R.H.S. Hall, the garden at Wisley, the *Journal*, the Society's examinations in horticulture, the Lindley Library, and other matters.

As a separate publication is issued the "Report of the Council for the year 1907," with statement of accounts, and lists of the Council and officers, honorary and corresponding members, Victoria Medal of Honour, Fellows, Associates, and affiliated societies for 1908. We make the following extracts from the report, which will be submitted at the 104th annual general meeting of the Society to be held at 3 p.m. on Tuesday next, February 11:—

Quiet, steady progress has again marked the past year.

RESEARCH STATION AND LABORATORY AT WISLEY.

The most important feature of the year's work, and one which, it is hoped, will be productive of far-reaching results, is the completion of the Laboratory and Scientific Research Station at Wisley. The opening ceremony was kindly performed by the Rt. Hon. Lord Avebury, P.C., F.R.S., on July 19, when several representatives of Government departments, prominent men of science and horticulture, and members of the Surrey County Council, were present. The occasion was one of great gratification, for it brought the realisation of a long-cherished, but long-deferred desire for a scientific station under the direct control of the Society, for research into the problems affecting plant life and plant disease at present confronting and baffling the gardener. Several very interesting speeches were delivered on the occasion which will be reported in the *Journal*.

Among the first subjects to be investigated are soil-sterilisation by steam as a means of destroying those pests of plants which live in the soil; the influence of sterilisation on the plants subsequently cultivated in the soil; the bacteria of the soil; etherisation of plants; and certain definite plant diseases. Each of these subjects will entail a large amount of laboratory work, as well as of experiment in the garden.

Mr. Frederick Chittenden, from the Chelmsford Laboratories of the Essex C.C., and for some years secretary of our Society's scientific committee, has been appointed director, having under his care both the research work, and the students' laboratory, the latter at present accommodating 24 young men. The students' training has thus been extended and improved, with a definite syllabus, and a time table apportioning their work between the gardens for practical work, and the laboratory for scientific study. The curriculum has received the approval of the Board of Agriculture, of the Science and Art Department [Board of Education], South Kensington, and of the Surrey County Council, who have asked the Society to co-operate with their efforts to afford horticultural education in the county, they themselves offering a certain number of scholarships in the Society's gardens to lads from the elementary and secondary schools of the county. The laboratory is recognised by the Board of Education as a technical school for grant, in conformity with whose regulations Messrs. W. A. Bilney, J.P., E. A. Bowles, M.A., W. Marshall, V.M.H., Harry J. Veitch, V.M.H., and the Rev. W. Wilks, M.A., have been appointed managers.

The question of the association of the Society in its education and research work at Wisley with the University of London has, at the request of the Council, been brought before the authorities of the University by Sir Albert Rollit, who is a member both of the Council of our Society and also of the Senate of the University, and, at the suggestion of the latter, the consideration of the subject has been adjourned.

DONATIONS, PRIZES AND SCHOLARSHIPS.

The Council acknowledge with heartiest thanks the receipt of £100 offered by Mr. Arthur W. Sutton, J.P., V.M.H., to inaugurate a prize scheme for the students at the gardens; and also the gift of an excellent photographic outfit for use at Wisley from Mrs. Hornby Lewis.

With reference to the prize scheme, which has not yet been definitely formulated, it is hoped that further donations will be forthcoming to secure an annual income of £15 to £20, so that the books or apparatus, given as prizes, may be worth working for, and serve as a real stimulus to the young men. The Council would also welcome the foundation of scholarships.

Whilst on the subject of donations, it should be mentioned that the Royal Dutch Bulb Growers' Society at Haarlem have kindly placed at the disposal of the Council a series of prizes, ranging from £2 2s. to £8 8s., for forced Hyacinths, to be competed for at the Society's Exhibition on March 31, 1908. There are to be six classes, three for amateurs and gentlemen's gardeners, and three for nurserymen. Full particulars will be found in the Book of Arrangements for 1908.

WISLEY GARDENS.

The new garden which was so generously purchased for the Society's use by Sir Thomas Hanbury, V.M.H., K.C.V.O., is gradually being brought into thorough working order. Much, however, still remains to be done. Various trials of flowers and vegetables have been carried out, and Mr George Massee, V.M.H., has conducted some original research work.

The number of visitors to the gardens admitted by Fellows' tickets during the year 1907 amounted to 8,818, as compared with 8,147 in 1906. This is exclusive of horticultural parties which were admitted by special arrangement, and would increase the total to over 10,000. The number would, no doubt, have been even larger but for the very unsettled weather of the summer of 1907.

WISLEY LAND TAX.

The Council were advised to redeem the land tax on the Wisley Gardens in anticipation of a greatly increased assessment of the property. This therefore was done, at a cost of £42 5s.

THE UNION OF HORTICULTURAL MUTUAL IMPROVEMENT SOCIETIES.

The union of mutual improvement societies is another development of the past year. The Council hope, by thus drawing the many isolated, but exceedingly useful, horticultural mutual improvement societies into federation with our Society, and with each other, to strengthen and encourage them, and generally to promote their welfare. It is intended under this scheme to gather from existing societies the most suitable rules and regulations and general constitution for the information of newly starting societies, to keep a list of lecturers willing to assist them, and to furnish them with printed lectures, when a lecturer cannot be secured, or unavoidably fails to fulfil his engagement. All affiliated societies are included in the union.

THE REPORT OF THE GENETICS CONFERENCE

The report of the International Conference on Genetics held in the summer of 1906 and edited by our secretary was published in the spring, and presented to all who were present at, or took any part in, the conference, and to all Fellows who had made application for it. The Council have received many congratulations upon the excellence of this report, which forms the most complete collection of information on this interesting subject yet published.

OBITUARIES.

The death roll among prominent Fellows of the Society is, unhappily, unusually heavy. First to be mentioned must be Sir Thomas Hanbury, K.C.V.O., the generous donor of the Wisley Garden. Then follow Sir Frederick Wigan, Bart., who for several years was a vice-president of the Society, and one of our most prominent growers of Orchids; and Doctor Masters, F.R.S., vice-chairman of the scientific committee for many years, and always a prominent figure at all the Society's meetings and conferences. The Society has lost another constant friend in Sir Michael Foster, F.R.S., whose horticultural work, especially amongst Irises, is well known to all. Mention must also be made of the Rt. Hon. Lord Battersea, Sir Alexander Arbuthnot, K.C.S.I., C.I.E., Major Bythway, Mr. Frederick Q. Lane, Mr R. I. Measures, the Hon. Mark Rolle, Lady Louisa Egerton, Mr. John Assbee, and Mr James Herbert Veitch.

MASTERS' MEMORIAL FUND.

The Council wish to commend the "Masters' Memorial Fund" to the support of the Fellows of the Society. In the latter part of the year a meeting was held to consider in what way the late Dr. Masters' memory, and his work for scientific horticulture, could be most suitably perpetuated, and it was at once felt by all that the most fitting memorial would be to establish foundation lectures on the application of science to horticulture, to be called "The Masters' Memorial Lectures," similar to existing foundation lectures in law, medicine, and other sciences. The Council gladly accepted the suggestion, and a circular letter was sent out to the Fellows, in response to which about £320 has thus far been received. It is greatly hoped that further donations may yet be made to the fund, in order that three lectures at least may be adequately endowed and so carry on Dr. Masters' memory to succeeding generations of gardeners.

RETIRING MEMBERS OF THE COUNCIL.

Under bye-law 60, the Hon. John Boscawen, Mr. J. Gurney Fowler, and Mr. William Marshall, V.M.H., the three members of the Council who have been longest in office, retire, but are proposed for re-election. The Earl of Tankerville, finding that distance from London prevents his regular attendance at the meetings of the Council, has asked to be allowed to resign, and the Council hope that Mr. E. A. Bowles, M.A., of Myddleton House, Waltham Cross, vice-chairman of the scientific committee, may be elected to fill the vacancy thus caused.

VICTORIA MEDAL OF HONOUR.

During the past year three vacancies in the roll of the Victoria Medal of Honour have occurred (Sir Thomas Hanbury, Sir Michael Foster, and Mr. Harry Turner), and Sir John Dillwyn Llewelyn, Bart., Mr. Henry Ballantine (the veteran head gardener to Baron Schroder), and Mr. George Dickson, the Rosarian, of Newtownards, Ireland, have been elected by the Council.

ANNUAL PROGRESS.

The following table will show the Society's progress in regard to numerical strength during the past year:—

LOSS BY DEATH IN 1907.

		£ s. d.
Life Fellows ... ... 23 ...		0 0 0
4 Guineas ... ... 4 ...		10 10 0
2 ,, ... 64 ...		128 2 0
1 ,, ... 78 ...		71 8 0
159		£216 6 0

LOSS BY RESIGNATION, &c.

		£ s. d.
4 Guineas ... ... 2 ...		8 8 0
2 ,, ... 105 ...		220 10 0
1 ,, ... 383 ...		402 3 0
Associates ... ... 16 ...		8 8 0
Affiliated Societies ... ... 14 ...		14 14 0
520		£654 3 0
Total Loss 676		£870 9 0

FELLOWS ELECTED IN 1907.

		£ s. d.
Hon. Members ... ... 4 ...		0 0 0
4 Guineas ... ... 4 ...		16 16 0
2 ,, ... 510 ...		1,071 0 0
1 ,, ... 690 ...		690 0 0
Associates ... ... 34 ...		17 17 0
Affiliated Societies ... ... 67 ...		38 17 0
Commutations 20		
= £443 3s. 0d		
1,209		£1,774 10 0
Deduct Loss		870 9 0
Net Increase in Income		£904 1 0

New Fellows, &c.	1,209
Resignations and Deaths	676
Numerical Increase	533
Total on December 31, 1906	9,467
Total on December 31, 1907	10,000

The Council are pleased to record that the total number of Fellows, honorary or corresponding members, associates and affiliated societies is now 10,000, which is believed to be the highest number belonging to any British Royal Society.

"JOURNAL."

Vol. xxxii. of the *Journal*, which deals with the work and lectures of the Society during the whole of 1906 was sent out in June last, and a further issue, Vol. xxxiii., containing the records of January to June, 1907, is about to be issued.

EXAMINATIONS.

The Society again held its three examinations: one in general horticultural knowledge; one, for school teachers, in cottage and allotment gardening; and one for men employed in public parks and gardens. These will be continued in 1908 with an addition to the "School Teachers' Examination" of elementary chemistry and biology, which subjects will be optional in 1908, but obligatory in future years. A fourth examination is also to be established—viz., for juniors under 19 years of age, in elementary gardening.

SHOWS IN 1907.

During the year 29 exhibitions, covering 35 days, have been held by the Society.

THE TEMPLE SHOW.

By the renewed kindness of the Treasurer and Benchers, the Society held its great show for the 20th year in succession on May 28, 29, and 30, in the gardens of the Inner Temple. The attendance was again a record one.

In 1908 a similar show has been arranged for May 26, 27, and 28, when there will be a private view open to Fellows' tickets only, on Wednesday, May 27, between the hours of 7 a.m. and noon. Fellows are particularly requested to notice that there will be no admission by payment to this private view; it will be reserved only for the annual tickets, transferable and non-transferable alike. This arrangement has been made to meet the wishes of many Fellows, and to obviate as far as possible the unpleasantness of overcrowding.

THE SUMMER SHOW.

On July 9 and 10 the Society's annual summer show was held in the park of Holland House, by the kind permission of Mary, Countess of Ilchester, who has most generously consented to the summer show of 1908 being again held there.

COLONIAL FRUIT SHOWS.

The two Colonial fruit shows, held in June and November, were most satisfactory, and the Council have, from time to time, received many expressions of thanks and of the debt of gratitude which the Colonies owe to the Society for them. They have also received many assurances of the encouraging stimulus these shows, and the Society's awards, have given to fruit-growers in the Colonies. This year the number and size of the exhibits has increased, and the judges, at the November show in particular, pronounced the fruit to be the best hitherto imported to England for excellence in quality, colour, and packing. Similar shows are to be held on March 5 and 6, June 11 and 12, and November 26 and 27, in the coming year. The Council hope that the Fellows will take a more active interest in these exhibitions, as they are organised at considerable trouble, and, as a matter of experience, visitors never fail to be interested and pleased with the immense variety of fruits, illustrative of the resources of Britain-over-the-Seas.

BURNHAM BEECHES.

At the request of the Right Hon. the Lord Mayor and the Corporation of the City of London, the Council, on August 20, appointed a small committee, consisting of Mr. F. J. Chittenden, Mr. Harry J. Veitch, V.M.H., Mr. A. D. Webster, and the Rev. W. Wilks, M.A., to examine and report upon the condition of the trees at Burnham Beeches. The committee devoted considerable attention to the matter, and towards the end of September issued their report to the Corporation, which will also be published in the Society's *Journal*. A letter of thanks has since been received from the Right Hon. Sir James Bell, the Lord Mayor.

DEPUTATIONS.

The Council have with much pleasure received and accepted invitations to send deputations to the Cornwall Spring Flower Society on April 7th, 1908; to the jubilee meeting of the Yorkshire Floral Society on June 16, 1908; and to the Durham, Northumberland and Newcastle-upon-Tyne Society's Show on July 1, 1908.

KINDRED SOCIETY SHOWS.

Many Fellows having expressed their disappointment at being excluded (except on payment) from the flower shows held in the hall by special societies, the Council have this year made it a stipulation that all special flower societies taking advantage as such, of the specially reduced terms for the use of the hall, shall admit all our Society's Fellows tickets free.

The following regulations have been issued, and Fellows will see from the announcement on their tickets which special societies have accepted the very liberal terms thus offered by the Society.

1. If a kindred society can, by arrangement, fix their show on a Wednesday or a Thursday following one of the R.H.S. fortnightly shows, then the kindred society shall have the gate money and the use of the hall free of all charge; attendants being provided by the kindred society, and free admission given to all holders of R.H.S. tickets.

2. A kindred society unable to adopt such Wednesday or Thursday shall have the use of the hall for £5 for the day, 6 a.m. to 6 p.m., the gate money being taken by the kindred society, who must provide all attendants; the tables will be set up by the R.H.S., and all R.H.S. tickets must be admitted free.

3. A kindred society unable to admit R.H.S. tickets must negotiate for the use of the hall on the ordinary scale of charges for letting.

REDUCED RAILWAY FARES.

At the request of a large number of Fellows, the Council prepared a petition to the railway companies of Great Britain, asking for similar privileges of reduced railway fares to those granted to some other societies. The petition was signed by nearly 3,000 Fellows, and met with a courteous but decided refusal.

Scientific Committee.

JANUARY 28.—*Present:* Mr. E. A. Bowles, M.A., F.L.S. (in the chair), Professors Percival and Boulger, Rev. W. Wilks, Messrs. W. Cuthbertson, H. T. Güssow, C. T. Druery, G. Massee, W. C. Worsdell, G. Gordon, E. M. Holmes, A. W. Sutton, J. Odell, A. Rolfe, J. T. Bennett-Poë, J. Douglas, F. J. Chittenden (hon. sec.), and numerous visitors.

Inheritance of pigment in Pisum sativum.—Mr. C. C. HURST, F.L.S., communicated the following note from Mr. E. A. BUNYARD, of Maidstone, on "The Inheritance of Pigment in Pisum sativum":—"The green and yellow colours of the cotyledons of Pisum sativum were selected by Mendel as one pair of constant differentiating characters, and from their apparent alternative inheritance the theory of gametic purity was deduced to explain results obtained in this species. The lack of any definite examination of the two colours in question led me to make some chemical and photo-chemical experiments as below, the pigments of the cotyledons alone being considered. The green pigment is, of course, chlorophyll, and thin sections mounted in glycerine show the chloroplasts well, and give the well-known 'hypochlorin reaction' when treated under the cover glass with glacial acetic acid. An alcoholic extract also gives the well-known bands in the red when spectroscopically examined, and the fainter bands in the blue and violet. The yellow colour is due to a pigment of the xanthophyll series, pigments which are always found in association with chlorophyll in the green parts of plants. The point, however, which is of importance is the gradual fading of the green (Sachs' 'Degradation of chlorophyll'), and the presence of the xanthophyll. The green chloroplasts, as the seeds attain maturity, gradually lose their green pigment, and when it has entirely vanished they are left in the cell as pale yellow globules. The yellow xanthophyll has, however, been present from the beginning, and the disappearance of the chlorophyll green has merely rendered it visible. The simultaneous presence of the two colouring matters can be demonstrated in this way. When a number of green cotyledons are steeped in alcohol a green extract, as referred to above, is obtained, and this fluid retains its green colour only so long as it is kept from light. When it is exposed to daylight, or even gaslight, it rapidly loses the green colour and fades to a yellowish tint. Upon examining this spectroscopically, it is found to have absorption bands in the blue and violet identical with that of an alcoholic extract made from yellow cotyledons. This fading of the green is seen in the autumnal colouring of leaves, and in an inverse order the slow development of cholophyll when etiolated plants are exposed to light. These facts, I venture to think, render it necessary to modify Mendel's original conception in this special case, as it is evident that the conception of a factor for green and one for yellow, and the alternative inheritance of each is hardly in harmony with the facts. As all cotyledons pass through the green stage, and certain only pass through to the yellow, I would suggest that the factor may be not a factor of '*quality*,' but a factor which extends or limits development." Commenting upon the foregoing, Mr HURST wrote:—"The above note by Mr. E. A. Bunyard is a valuable contribution to our knowledge of the nature of Mendelian characters in Peas. According to Mr. Bunyard's results, green Peas contain invisible yellows at all stages of their development, while yellow Peas contain green in the early stages only. A yellow Pea may, therefore, be regarded as due to the presence of a factor which causes the green to fade at an early stage of development, while in the green Pea this factor is absent. The Mendelian units concerned are therefore not simply yellow and green, as Mendel supposed, for all green Peas contain the yellow element as well as the green, but would appear to be rather the presence and absence of a factor which causes the green to fade."

Hybrid Brassicas.—Mr. A. W. SUTTON read a paper, which he illustrated by means of lantern slides, upon "Hybrid Brassicas," similar to that delivered before the Linnean Society recently and reported and illustrated in these columns

NATIONAL CHRYSANTHEMUM.

(ANNUAL MEETING.)

FEBRUARY 3.—The annual meeting of the above society was held on this date at the Essex Hall, Strand, Mr. Thomas Bevan presiding.

A letter was read from Chas. E. Shea, Esq., the president, regretting his inability, through illness, to be present. Sir Albert Rollit also wrote explaining the cause of his absence. On the motion of Mr. C. H. Curtis, the annual report and balance sheet were received.

EXTRACTS FROM THE REPORT OF THE EXECUTIVE COMMITTEE.

During the 12 months 77 new members (12 Fellows and 65 ordinary members) were added to the roll as compared with 60 in the previous year. Whilst it is satisfactory to note that there was an increase in the additions, your committee would point out that there is still room for a very great improvement in this direction.

The list of affiliated societies is in itself a tower of strength, and in this matter the National Chrysanthemum Society occupies a unique position amongst societies which are devoted to the culture of one particular flower. On December 31 there were 110 suburban, provincial and Colonial societies on our register of affiliated societies. During the course of the year, several protests raised by exhibitors in connection with the shows of affiliated societies were submitted to your committee, and in each case the most careful consideration was given to the facts, and the committee's decisions were loyally accepted by the interested parties.

Exhibitions were held in October, November, and December at the Crystal Palace as in former years. Your committee are pleased to report that the number of entries in the various classes showed an increase of about 33⅓ per cent. over the previous year. This is all the most satisfactory when it is remembered that many of the new exhibitors, although enthusiastic Chrysanthemum growers, were in reality maiden exhibitors so far as this society's shows were concerned, and it may therefore be reasonably hoped that the majority, if not all of them, will be competing again in 1908 with increased zest. The quality of the exhibits was exceptionally high, both as regards the individual blooms and the general effect, and this in spite of a rather unfavourable season. The trade exhibits also showed an increase in number over the previous year, and were quite up to the usual high standard.

The exhibition of Chrysanthemums as grown for market was held at the Foreign Flower Market, Covent Garden, on Wednesday, December 11, by kind permission of His Grace the Duke of Bedford, K.G. The entries at this show were not quite so numerous as on previous occasions, but the exhibits were of a very high quality. In connection with this show, it may be mentioned that your committee heard with extreme regret of the death of Mr. J. Assbee, the Superintendent of Covent Garden Market, which occurred in November last, and a letter expressing the sincere condolence and sympathy of the members of the society was forwarded to the late Mr. Assbee's widow.

The shows for 1908, which will be held at the Crystal Palace, have been fixed for Wednesday and Thursday, October 7 and 8; Wednesday, Thursday and Friday, November 4, 5, and 6; and Wednesday and Thursday, December 2 and 3.

The best thanks of the society are again due to the stewards and other gentlemen who assisted at the shows, and also to Mr. G. L. Caselton, Superintendent of the Gardens, at the Crystal Palace, who spares no pains to make the shows successful from every point of view.

Twenty-six meetings of the Executive Committee and sub-committees were held in 1907. Members were also in attendance at the society's shows at the Crystal Palace and Covent Garden, and the Hon. Foreign Corresponding Secretary also attended the French Society's shows in November at Paris and Orleans.

Seven meetings of the Floral Committee were held during the season, four at Essex Hall and three at the Crystal Palace. Mr. D. B. Crane was unanimously re-elected chairman at the first meeting and presided over all the deliberations of the committee. During the season, 215 entries were recorded, and the following awards were made, viz.:—Thirty-two First Class Certificates and 11 Commendations, whilst in several cases the exhibitors were asked to submit the blooms to the consideration of the committee on a future occasion. Silver Medals were also awarded to Mr. W. J. Godfrey, Exmouth, and Mr. H. W. Thorp, Worthing, for interesting collections of new varieties submitted at the meeting held on October 28.

As foreshadowed in the last report, the society's "Year Book" was issued early in 1907, and was well received by the members. All members received free copies, but the sales to the general public were very small, and the income from advertisements was not as large as had been hoped. For this reason your committee decided with regret that it was inadvisable to incur this expense again in 1908. They still adhere, however, to the opinion expressed in the last report with regard to the importance of issuing publications dealing with the various aspects of the Chrysanthemum.

The annual dinner was held at the Holborn Restaurant on November 26. The chair was occupied by the president of the society, Charles E. Shea, Esq., who was supported by Sir Albert Rollit, D.C.L., LL.D., and about 100 other guests and members.

The committee again desire to tender their best thanks to the donors of special prizes, viz.: The President (Chas. E. Shea, Esq.), the Ichthemic Guano Company, Mr. R. Sydenham, Mr. J. Williams, Mr. J. J. Simpson, Mr. W. Wells, Mr. F. G. Oliver, and Messrs. Cragg, Harrison & Cragg.

The ordinary income of the society showed an increase over the previous year, but having regard to the special expenditure the committee deemed it advisable to transfer £70 from deposit account to general account. They have, however, resolved to so transfer not less than £25 to deposit account from the current year's income and to continue the same policy until that account is restored to at least its original figure. The prize money in respect of all the shows has been paid.

Your committee received with the deepest regret the announcement of the President that in consequence of continued ill-health he would be unable to continue to fill that office after the close of 1907. Mr. Shea has been president of the society for the past five years and your committee wish to place on record their sense of indebtedness to him for the many valuable services he has rendered to our society.

Under these circumstances your committee have much pleasure in announcing that Sir Albert Rollit, D.C.L., LL.D., has consented to be nominated for the office of president during the coming year, and his name will be submitted to the members at the annual meeting.

Arising out of the report, Mr. Simpson enquired what the loss to the society had been in connection with the publication of the *Year Book*, and Mr. Green, the treasurer, replied that it was about £50. It is, however, only fair to explain that this book was prepared for gratuitous distribution among the members, and, under such circumstances, could not be expected to return a profit. On account of shortness of funds, the committee felt that for the present they could not recommend a continuation of its issue.

Another enquiry arising out of the subject was the probability of an audit of the November show. The chairman stated that one would not be published this year, as the matter had been overlooked.

The election of officers was then proceeded with, the following being the results:—President, Sir Albert Rollit, D.C.L., LL.D.; treasurer, Mr. John Green; chairman of Executive Committee, Mr. T. Bevan; vice-chairman, Mr. E. F. Hawes; foreign secretary, Mr. Harman Payne; general secretary, Mr. R. A. Witty; auditors, Messrs. Lake and Scammell. One-third of the Executive Committee retiring, according to rule, the following were elected for three years, viz., Messrs. Ballantine, Cassidy, Cragg, Crane, Curtis, Cull, Emberson, Felton, Foster, McKerchar, Newton, Prickett, Seabrook, Springthorpe, and Tyler. Mr. C. E. Shea's name was added to the list of vice-presidents, and, on the motion of Mr. Harman Payne, a vote of thanks was passed to him for the services he has rendered to the Society during the term of his office as president.

An alteration in the rules, after a little discussion, was adopted, relating to the appointment of judges. In future the society will not be compelled to go outside of its own committee for judges at the shows, and the post of judge will be an honorary one.

A delegate from the Eastbourne society drew attention to the subject of juvenile exhibitions as a means of increasing the interest in Chrysanthemum culture. The election of new members brought the meeting, which was rather thinly attended, to a close.

DEBATING SOCIETIES.

PANGBOURNE GARDENERS' MUTUAL IMPROVEMENT.—The third annual dinner in connection with this association was held in the George Hall, Pangbourne, on January 22, when over 70 members and friends were present. The president, A. Petrocokino, Esq., occupied the chair, and was supported by several of the vice-presidents. Messrs. H. G. Cox and G. Hinton were present as representatives of the Reading Association, and Messrs. Young and Forrester, of the Theale Gardeners' Association. An enjoyable programme of vocal and instrumental music was gone through. *E. H. D.*

DEVON AND EXETER GARDENERS'.—At the last meeting of the association an animated discussion on Summer-pruning took place. It was introduced by Mr. Slade, of Poltimore Park, and joined in by several of the members. Although various opinions were expressed as to the best time for carrying out the operation, the advantages of Summer-pruning, when judiciously done, were generally admitted.

——— On February 1, at the Turk's Head Hotel, the members sat down to supper under the chairmanship of Mr. W. Mackay, the treasurer of the association, when a very pleasant evening was spent. A special invitation was made to the younger members to come forward with essays and help in the discussions. The claims of the Gardeners' Royal Benevolent Institution were urged on behalf of the local auxiliary which is doing excellent work in the County of Devon. *J. H.*

SALISBURY AND DISTRICT GARDENERS'.—There was a large attendance at the last meeting of this society to hear Mr. Parrott, representative of the Bath Gardeners' Association, lecture on "Fuchsias." The lecturer dealt chiefly with the subject of specimen plants for exhibition purposes. The month of March was stated as being the best time to insert cuttings. The cuttings as soon as rooted should be given every encouragement and during their growth should never be permitted to become pot-bound. If kept growing for eighteen months splendid specimens, well balanced from top to bottom, should be obtained. *W. Y.*

WARGRAVE AND DISTRICT GARDENERS'.—The annual meeting was held on January 8, when the report and balance sheet were adopted. From the report it appears that 23 new members joined during 1907, and allowing for removals and one death among the members, at the end of the year the roll stood at 59 ordinary and 21 honorary members. The balance sheet showed that £15 was carried to a reserve fund and after all expenses had been met there was still a balance in hand of over £6. A sum of five guineas was voted as an honorarium to the hon. sec.

——— On January 15 the sixth annual social gathering of the members took place in the Woodclyffe Hall. There was a large company to tea and it was further augmented afterwards.

——— On January 22 Mr. J. T. Blencowe, gardener at Wilminster Park, gave a lecture on "Microscopic Plants" illustrated with a large number of lantern views.

BRISTOL AND DISTRICT GARDENERS'.—The best attended meeting of the present session was held on Thursday, January 30, at St. John's parish room, Mr. I. C. House in the chair. "Begonia Gloire de Lorraine" was the subject for discussion, and it was introduced by Mr. T. Parriott, representative of the Bath Debating Society. In his opening remarks the lecturer briefly referred to the origin of this Begonia, stating that B. socotrana and B. Dregii were its parents. The best mode of propagation, Mr. Parrott said, is by leaf cuttings, which are preferable to stem cuttings, making better plants, because plants grown from leaves do not produce flowers in their growing period as is the case with plants raised from ordinary cuttings. The cultivator should obtain well-matured leaves in December and January, insert them in boxes of sand or Cocoanut fibre, and place them over a bottom heat of from 75° to 80°. On the appearance of growths the cuttings should be potted into 3-inch pots, and finally into 6-inch pots, using a compost consisting of two parts Cocoanut fibre, one part leaf-soil, and one part fibrous loam, adding sand and charcoal. The soil should not be made firm. The plants need to be kept in a cool house in summer and should flower in an atmospheric temperature of about 60°. For three plants in flower Mr. Curtis won the 1st prize and Mr. Wakefield the 2nd prize. Mr. Curtis also won the 1st prize for two Orchids. *H. W.*

LIVERPOOL HORTICULTURAL.—A meeting of this association was held on February 1, Mr. Forster in the chair. The lecturer for the evening was Mr. H. Curtis, superintendent of the parks and gardens at Widnes. The subject was "Some Hardy Garden Flowers," more especially those suitable for towns and smoky districts.

REDHILL, REIGATE AND DISTRICT GARDENERS'. This society held its fortnightly meeting at St. Mathew's parish rooms, Redhill, on January 21. A paper was read by Mr. W. Turnham (representative of the Reading Gardeners' Association), on "Trenching and its Advantages." *G. P. S.*

CHELMSFORD & DISTRICT GARDENERS'. At the weekly meeting held in the County Laboratories on January 24, Mr. H. Stiles, of Writtle Wick, gave an interesting lecture on "Mushrooms and their Cultivation." The lecture was followed by questions which were answered impromptu by members as they were called upon.

——— On the 31st ult., Mr. Orpen, of West Bergholt, read a paper on "Rose Culture." R. Miller, Esq., St. Leonards, Ingatestone, president of the association, was in the chair, and about 90 members were present. The association is to be congratulated on its flourishing condition, and the very useful work it is doing.

DORCHESTER GARDENERS' & AMATEURS'.—The annual meeting of this society was held recently at Ermington House, the residence of Mr. C. S. Prideaux, the hon. sec. of the society. Mr. H. J. Hellier presided. The report showed that the interest of the members had been well sustained. The series of lectures had proved of an instructive character, and the outdoor meetings held in the summer were greatly appreciated. Prizes had, as usual, been offered for exhibits of fruit, flowers, and vegetables, and had been productive of keen competition. General satisfaction was expressed with the financial statement. The chairman announced that a letter had been received from Mr. Nelson M. Richardson (president of the Dorset Natural History and Antiquarian Field Club), who had kindly consented to judge the members' essays on "Six Insect Pests," and for which two prizes of £1 and 10s. were offered by Captain R. Dymond (president of the society). Mr. Richardson awarded the premier prize to Mr. Spiller, and the second to Mr. Stone. The assistant hon. sec. informed the members that at the next meeting, to be held on Monday, February 24, Mr. P. W. Lasham (from Messrs. Sutton & Sons, Reading) would lecture on "Early Potato Cultivation."

CROYDON & DISTRICT HORTICULTURAL.—This society made a capital opening of their new session on January 29, when Mr. R. Edwards, Beechy Leys Gardens, Sevenoaks, read a paper on "Hardy Fruits," or perhaps what may be described as part of that extensive subject, for he confined his remarks to Apples and Pears. Mr. Edwards is a successful grower, as is evidenced by his exhibits at the Crystal Palace and other big shows. To show the character of the various Apples, he staged 72 varieties, all of which were excellent types, and acted as a medium to illustrate his remarks. Besides Mr. Edwards' exhibit there was a fine seedling Amaryllis, staged by Mr. H. Peckham. Mr. M. E. Mills put up a vase of White Chrysanthemums, "Nellie," and a fine pot of Cypripedium insigne; and Dr. Jackson sent three dishes of Pears.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending February 5.

The warmest week at yet this winter.—The first day of the week was cold, but since then the day temperatures have been about seasonable. The nights were, however, nearly all cold, and on the coldest night the exposed thermometer registered 13° of frost. The ground temperatures are at the present time rather low, the reading at two feet deep being about 4° colder, and at one foot deep about 2° colder, than is seasonable. Slight rain fell on three days, and on one of them there was a light fall of snow. It is now nearly four weeks since there was any fall of rain or snow worth mentioning, and for over a fortnight there has been no measurable percolation through either of the soil gauges. There has been a good record of sunshine which amounted on an average to three and a half hours a day, or nearly double the mean duration for the time of year. The wind has been, as a rule, high, and in the windiest hour on one day the average velocity reached 23 miles—direction west. The mean amount of moisture in the air at three o'clock in the afternoon fell short of a seasonable quantity for that hour by as much as nine per cent.

JANUARY.

Frequent changes in temperature.—This was the coldest January for 11 years. The most noteworthy feature, however, as regards temperature was the frequent changes. In fact, there occurred three distinct cold periods, and three distinct warm periods, during the month. On the warmest day the temperature in the thermometer screen rose to 53°, and on the coldest night the exposed thermometer indicated 25° of frost the lowest reading in January for 13 years. Rain, hail, or snow fell on 13 days, to the aggregate depth of 1¼ inch, or ¾ inch below the January average. Virtually the whole of the total rainfall was deposited on two consecutive days in the early part of the month, for at no other time did the fall for any one day reach even a tenth of an inch. On as many as 21 days there was no measurable percolation through either of the soil gauges. The sun shone on an average for 1½ hours a day, which is about a seasonable duration. On 15 days no sunshine at all was recorded, and on five other days the record of bright sunshine amounted to less than an hour. This was, on the whole, rather a calm month. On two days, however, the mean velocity for the windiest hour reached 23 miles direction west. The average amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by 1 per cent.

OUR UNDERGROUND WATER SUPPLY.

Since the winter half of the drainage year began in October last the total rainfall has exceeded the average for those four months by 2 inches, which is equivalent to an excess of 46,370 gallons per acre in this district. At the same time last year there was an excess of 58,820 gallons per acre. *L. M., Berkhamsted, February 5, 1908.*

ENQUIRIES AND REPLIES.

BISULPHIDE OF CARBON FOR VINE BORDERS (see p. 80).—Bisulphide of carbon is a highly volatile fluid of a most disagreeable smell, and is never likely to be used largely for the purpose mentioned. In the first place, the necessary amount of labour and expense are deterrent, and, secondly, the poisonous nature of the vapour renders great care necessary. Its application to the borders either whilst the Vines are active or dormant is fraught with danger, as too much would immediately injure them. When used, however, it should be during the latter period, as the circumstances are then more favourable. The quantity which may be regarded as safe per cubic yard would be half an ounce or less. Holes are made 18 inches or more in depth, and the liquid poured therein; these are then instantly filled, and covered with a stone. Another method is to place a stone at the bottom of the hole, the requisite quantity of the liquid placed in a small bottle is then laid thereon, a stake of some sort sufficiently long to rest on the bottle and extend a little above the surface is placed in position, and the holes filled in. A tap on the head of the stake later with a mallet or hammer will smash the bottle and liberate the fluid. The vapour spreads its way through the interstices or air-chambers of the soil, destroying all insects, &c., within its reach. If *W. H. P.* is without experience, it would be advisable for him to experiment very carefully at first, or seek the aid of some experienced person. Or, perhaps, better still, have recourse to the insecticide "Vaporite," which is both safe and effective, answering the same purpose but unaccompanied with the risk that attends the use of Bisulphide of Carbon. *G. D. R.*

MOLES.—Can any reader tell me how to exterminate moles from a lawn? They seem to be too artful to go into traps set in the usual manner. Can the moles be poisoned in any way? *F. B.*

ANSWERS TO CORRESPONDENTS.

AERIAL ROOTS ON VINES: *A. H. A.* The canes are induced to make adventitious roots owing to one or several causes. The atmosphere of the house may be kept too hot and too moist, without sufficient ventilation, or the roots may be growing in a cold, badly-drained border. Such roots are the natural result of growing vines in forcing houses, but if they are produced in excessive quantities, it is an indication that the roots below the ground level are less active than is desirable, and this condition is one which should be remedied.

BOOKS: *J. M. Ferns for Amateurs*, by George Schneider, new edition, obtainable from our publishing department, price 3s. 10d., post free.

COAL ASHES: *Inquirer.* Finely-sifted coal ashes have little or no manurial value. They are sometimes placed upon garden paths in out-of-the-way places, and they might be of some use if mixed with heavy clay soil in modifying the physical properties. We should not use coal ashes upon lawns. Wood ashes are quite different in nature; they form an excellent dressing for lawns, and may be used with good effect in every part of the garden.

CREEPERS FOR THE BACK WALL IN AN EARLY VINERY: *A. B.* Bougainvillea glabra, Cissus discolor, for leaf effect, and Passiflora princeps. Some amount of direct sunshine should be afforded the flowering plants to enable them to produce good floral effects. There is always the danger of introducing mealy bug or other insect pests with plants cultivated in vineries, and it will be necessary for you to keep a very strict watch on such plants.

CUCUMBER AND TOMATO PLANTS: *J. I.* The unsatisfactory condition of your young Cucumber and Tomato plants is probably due to unsuitability of the soil, and the conditions under which they were potted, or it may be the result of your having been working in your propagating house in the evenings by the light of a naked acetylene lamp. We presume the lamp was placed pretty close to, if not actually on, your potting-bench when potting your young plants, and owing to the seedling plants being at the time subjected to a slight check in the process of being potted into 3-inch pots they would be the more easily affected by injurious fumes. The fact that your plants were strong up to the time of potting-off, and that they made but little growth since they were potted, and that this growth is much weaker above the seed-leaves than it is at their bases, seems to indicate that the use of the naked acetylene lamp in the manner described may possibly have had something to do with the trouble. You may rest satisfied that the coating of the gutter-boards with Stockholm tar before Christmas, and which you say was thoroughly dry before the plants were up, had nothing to do with the trouble, as the tar-gas, if any, arising from the tarred gutter-boards would be lost in the external atmosphere. Your soil being rather heavy for Cucumbers, you should have added to it rather more than two-parts of well-rotted stable manure or good leaf-mould, mixing this well together after placing it in the propagating house to become warmed before being used. If you have not already transferred your plants to pots 5 inches or 6 inches in diameter, you will do well to employ a similar compost to that we have described. Having sown your Cucumber seed on December 19 and maintained an atmospheric temperature of from 70° to 75°, your plants, had they gone on all right, should long ere this have been placed in either 5-inch or 6-inch pots. They should have attained a height of 18 inches, and developed six proper (rough) leaves by this date, and be ready for planting on the ridges at 2 feet apart next week. We presume that you have sown a fresh batch of seed, so as to be prepared for the worst. It is always advisable to do this when the plants resulting from the first or previous sowing are not so promising as could be desired. With regard to the condition of your Tomato plants, the symptoms may be accounted for in the same way as the affection of the Cucumber plants, but it may also be that sufficient care has not been exercised in the application of water at the roots. The stems being thin would convey the idea that the plants were not placed sufficiently near to the roof glass.

CURRANT-BUD MITE: *S. E. N.* Your bushes are doubtless affected with the Currant-bud mite, which has caused the swollen buds you have described. You will find particulars and illustrations in *The Calendar of Garden Operations*, price 7½d.; or *The Book of Garden Pests and Plant Diseases*, by R. Hooper Pearson, price 2s. 10d., post free, from our publishing department.

DYEING MAHONIA LEAVES: *W. H.* There is no preparation that will remain permanent after exposure to the atmosphere, as they are all made from aniline dyes.

EUPATORIUM ODORATUM: *A. E.* This is an extremely easy plant to cultivate. Cuttings may be inserted in the spring, and when they have made roots should be potted on in the usual way until the summer, when they may be either placed directly in their flowering pots or planted out in a border. If the latter plan is adopted, lift the plants at the end of September, pot them up and leave them out of doors for a day or two, afterwards syringing them occasionally if the weather is dry. The plants may then be removed to a light position in the greenhouse, and under good treatment they will flower well.

FRANCO-BRITISH EXHIBITION: *C. B. G.* If you wish to become a member of the Garden Club you should write to the Secretary of the Franco-British Exhibition, 56, Victoria Street, Westminster.

LILY OF THE VALLEY: *Lily Failure.* Your crowns of Lily of the Valley have undoubtedly been killed by frost. The mould on the roots is the common blue mould which may be found on all kinds of dead vegetable matter. It is suspected that under favourable circumstances it may become parasitic, but it is hardly likely in this case.

NAMES OF FRUITS: *E. R., Gloucestershire.* The Pears are 1, Bergamotte Esperen; 2, Knight's Monarch; the Apple is French Crab.—*J. S.* 1, Winter Bon Chrétien; 2, Catillac; 3, Too small to be identified; 4, Withington Fillbasket.—*Baker.* 1, Uvedale's St. Germains; 2, Specimen decayed; 3, Vicar of Winkfield; 4, Knight's Monarch; 5, Van Mons. Leon Leclerc; 6, Too small to be identified.—*Wheeler & Son.* Franklin's Golden Pippin.—*F. T.* 1, Leon Leclerc de Laval; 2, Nec Plus Meuris; 3, Specimen insufficiently good.—*J. Ackers.* Can you send us a fruit in a state of better preservation?

NAMES OF PLANTS: *H. R.* 1, Pteris serrulata; 2, Pteris tremula; 3, Adiantum cuneatum.—*F. T.* 1, Epidendrum ochraceum; 2, Epidendrum virens; 3, Oncidium cucullatum, 4, Aerides japonicum.

POTATO SIR JOHN LLEWELYN: *M. L.* It is probable that the disease destroyed the haulm before the tubers were sufficiently ripened to possess good edible qualities. This variety needs a long season of growth, and the tubers are not of the best unless this is provided. Get your seed tubers nicely sprouted before planting them, and plant them out early in the season. Being a very heavy cropping variety, it seldom succeeds well in heavy soil, therefore plant the tubers in light, sandy loam if this is possible.

SPRAYER: *J. M.* There are many forms on the market of different delivering capacity. It is essential that the liquid should be delivered in the form of a very fine spray such as is obtained from a "Vermorel" or "Riley" nozzle. Your best plan would be to visit a dealer in these appliances, and after seeing them in operation select the one that commends itself for the particular purposes you require it.

TOMATO FORCING.

THE cultivation of Tomatos in the greenhouse has assumed such extensive proportions, both in this country and in the United States, that the following information from the Ohio Agricultural Station may be of value to English growers. The results extend over 12 years, and for spring and early summer market the Tomato crop has proved uniformly profitable. At the season when Tomatos can be grown in the greenhouse to the best advantage, they are more remunerative than either Lettuce or Cucumbers during the same period. The crop, therefore, is one well deserving the attention of those engaged in vegetable forcing.

All the Tomatos have been grown on raised benches with about 6 inches of soil. For this crop, benches have the advantage over ground beds in earlier maturity of fruit, and as the price of Tomatos is always much higher during the first part of the season, early maturity is a great advantage. The average yield has been 2 lbs. 4 ozs. per square foot, or 9 lbs. per plant, the plants having been grown 2 feet apart each way. Thus the yield of one house with 960 square feet of bench space available for Tomatos was 2,160 lbs. The prices ranged from 20 to 5 cents per pound, but averaged 12 cents (6d.). Figuring on a basis of 12 cents per pound, one house gave a return of 259.20 dollars, equal to about £94 for one crop of Tomatos, while the average return would be about £54 per house. In 1904 picking began June 10, a little later than usual. From June 10 to July 8, 2,000 lbs. of No. 1 grade fruit were gathered and sold at 15 cents per pound. From July 8 to July 22, 1,000 lbs. were picked and sold at 12 cents per pound. From July 22 to August 1, the product was 600 lbs. and sold at 10 cents per pound. Thus up to August 1, 2,400 feet of bench space had given an actual yield of 3,600 lbs. of Tomatos, which sold for 480 dollars, equal to £100, representing an income of 20 cents, or 10d., per square foot.

Sub-Irrigation versus Surface Watering.

The Tomato requires an abundance of water in the soil for its best development, especially in greenhouse culture when grown as a spring and summer crop. In these experiments it was found that by repeated watering on the surface, the soil, unless more porous than the average greenhouse compost, becomes consolidated unless considerable care is exercised in watering; the lower portion of the bed will often become quite dry, even though the upper portion may be thoroughly soaked. This not only results in a check to the growth of the plants, but if it occurs after the fruit has become well developed it will often cause a considerable loss from dry rot. On the other hand, when the water is allowed to rise by capillary attraction, as is the case when sub-irrigation is practised, the soil is kept open and porous and in good condition for the free access of air, and it acts as a sponge in taking up and holding a large amount of water. Sub-irrigation not only gives the best growth of plants and highest yield, but it also serves as a check to the disease known as dry- or tip-rot.

The practice of mulching with strawy manure accomplished much the same results as sub-irrigation. It has been found, however, more beneficial with surface watering than with sub-irrigation. The best results were obtained by mulching as soon as the Tomatos were planted in the bed, and allowing the surface of the mulch to become dry and remain in that condition for some time. If the mulch is kept wet on the surface from the start, the presence of the moisture seems to bring about conditions which promote disease. Towards the close of the season the mulch may be surface watered, and thus wash some of the fertility out of the manure into the soil; it will thus be available for the crop when it is most needed. Where the water supply is scanty, a mulch should be used whatever method of watering is employed, and it will be found beneficial in all cases.

The usual custom at the Ohio Station is to set Tomato plants 2 feet apart each way. For two years experiments have been made with plants set 12 inches, 18 inches, and 24 inches apart each way. Those planted 12 inches apart were trained to one stem only. The final results showed that the plants set 1 foot apart each way gave the highest yield per square foot of bench surface, with a loss of nearly one ounce in average size of fruit. The plants set 18 inches apart and trained to two stems were second in yield, and the average size of fruit was not affected. These facts indicate that in planting 2 feet apart each way, the plants have not been crowded as closely as they might have been, in order to secure the highest yield per square foot. Different varieties, however, will not always behave quite alike in the respect of yield.

For the spring crop of Tomatos, it is usual to sow the seed in flats the beginning of December. When the plants are of sufficient size for handling, they are transplanted, or "pricked off," into flats, setting them about 3 inches apart each way. As soon as there are any signs of crowding they are again transplanted, but this time into pots. Where time is limited, as is usually the case with greenhouse work, the plants can be transplanted from the flats into 2½-inch pots, and later into 4-inch, where they can remain until ready to be planted in the beds. The aim should be to secure a good, strong, stalky plant, 10 to 15 inches in height. At the same time Tomato plants are set in the bed, Lettuce plants are set between the Tomato rows, and as this happens at the time of year when the days are lengthening, the crop of Lettuce grows quickly, and is out of the way before the Tomato plants are of sufficient size to do any harm to the Lettuce plants. But when the Tomato plants are as close as 1 foot each way, it will not pay to grow a crop of Lettuce along with them. *J. J. Willis, Harpenden.*

GUNNERA SCABRA MAJOR.

Gunneras in their larger forms are among the boldest of garden plants, and some, even of those who do not cultivate these species, may carry with them the recollections of many glorious plants of the great Gunnera manicata, which forms almost a thicket of its great leaves, each of them sometimes 9 feet and more across. Such plants are to be seen, and in the sister isle this glorious Gunnera seems to attain to even finer dimensions than in Great Britain itself. The magnificent examples at Narrowwater Castle, St. Anne's, Clontarf, and other fine Irish gardens, ever recur as one thinks of this great plant.

Gunnera scabra, if less imposing in size, has a greater ruggedness of character and a distinctive appearance which renders the two in no sense rivals, but rather companions. The former is now pretty generally known, but there are as yet but few who are acquainted with its variety, called G. scabra major, a still bolder and more massive plant, which originated in the wonderful nursery of Mr. Thomas Smith, at Newry, where I first saw the original plant a few years ago. It is a variety which at once appeals to us as an improvement upon the ordinary form, and as one which has a future before it in gardens where this Gunnera is quite hardy, or in those where it can be accommodated with some slight covering about its crowns in winter. It is all but hardy, even in comparatively cold parts of the United Kingdom, but there is a chance that some hard winter or some unusually cold snap will prove fatal to it unless some protection is afforded. A little will suffice, either in the form of straw or other loose litter, or even ashes heaped over the crowns, until danger from frost is past. One cannot too strongly recommend this giant form of G. scabra to admirers of such plants as the bolder Gunneras, which, after all, are much superior to the smaller and dwarfer species such as G. magellanica, a plant more adapted to the rock garden. *S. Arnott.*

NOTICES OF BOOKS.

*"WOBURN EXPERIMENTAL FRUIT FARM."

THE eighth report of this institution has just been issued, and contains a considerable amount of valuable information on insecticides and fungicides. The introduction to the report ought to be read by everyone who is interested in these questions—and what gardener is not?—for it may serve to correct many erroneous notions about the use and abuse of these substances. The various methods of emulsifying the mixtures are treated both from a practical and a theoretical standpoint; and the utility, from a financial point of view, of really scientific investigations in these matters is proved by the discovery that the cost of Bordeaux Mixture may be reduced by three-fifths without in any way diminishing its effectiveness. The Report forms one of the most important of recent contributions to the literature of scientific and practical horticulture.

The price of the volume is half-a-crown, and a summary of the results therein described and discussed may be obtained for threepence by those who do not desire to enter into the details of the work.

†"FLOWER GROUPING.

BOOKS embellished with coloured pictures of gardens increase in number unceasingly. The present work, with 56 coloured sketches by Miss Margaret Waterfield, is the most recent of this attractive class of garden books. Miss Waterfield handles her brush and pencil in a way that has caused her, since her book on *Garden Colour* was published two years ago, to be recognised as at once a dainty and a bold executant. For the purposes of this book she has been to Scotland and to Ireland in search of subject-matter for her brush, and to the pictures painted in these countries others from the South of England are added, together forming a sumptuous collection. It would only lay one open to criticism to attempt to decide which of these should be regarded as the best, but one may at least confess, without fear of reproach, which is the most attractive to one as an individual. Such is "Campion and Pheasant's Eye," Saltwood; "Tiger Lilies," Camp Cottage, Comrie; "Crocuses," Woodlands, Cobham; "Chionodoxa," Kew Gardens; "Onopordon tauricum," Nackington, Canterbury; "Gunnera, &c.," Ashford, Co. Wicklow; and "Tritomas," Dalhousie, Midlothian.

The accompanying letterpress is varied and interesting. Miss Waterfield herself contributes many pages, and besides the more technical matter, such as articles on Crocuses, Tulips and wild gardening, she has written appreciative essays on Scottish and Irish gardens. Her helpers are numerous, of whom the best known is E. V. B., whose recollections of Scottish gardens has led her to mildly curse the bedding-out system of flower gardening in the belief it still flourishes in her native land! Miss P. Graham Stirling, who writes of Scottish gardens, merely mentions the ribbon border as a cast-off fashion, and it is obvious, from the remarks of others, that Pelargoniums and such-like plants are not now so intrusively apparent in Scotland as they used to be.

The Hon. Emily Lawless, to whom Irish gardens are entrusted for review, is not a whit behind in garden patriotism. She, like Miss Graham Stirling, recognises the drawbacks of the climate of her country, but she does not grumble on that account, rather she seems to want her readers to believe that the climate and the gardens are in loving agreement.

The other contributors include Miss Rose G. Kingsley, who writes of climbers, and makes the strange pronouncement that Polygonum Baldschuanicum does not flower till autumn! Mr. S. W. Fitzherbert tells of the many uncommon plants which, growing in the open in Cornwall, make its gardens different from those in other parts of the country. Mr. S. Arnott treats of Lilies. Roses and water gardens employ the pen of Mr. Frank Galsworthy. Rhododendrons and Azaleas that of Mr. W. P. Wright. Miss Curry contributes notes on her favourite Daffodils, Mr. W. W. Richmond Powell on Eremuri, and Mr. R. P. Brotherston on annuals for Scotland.

The work is marred to a considerable extent by the incorrect spelling of plant names. These inaccuracies are unusually numerous, and some of the instances are of a glaring character.

*"SWEET PEAS AND THEIR CULTIVATION FOR HOME AND EXHIBITION."

A LADY who wrote pleasantly of flowers 80 years ago was bold enough to confess her preference for Sweet Peas over all other flowers, not excepting the Rose. Many things have happened since then, and had she known the Rose as it is represented in gardens to-day, one might venture to harbour a doubt whether she would have made so sweeping a statement. Still, it cannot be gainsaid that, popular as is the Rose, its popularity is not greater than that of the Sweet Pea, and it is just as well that we can admire both without examining too closely the place either holds in our affections. The author, in the present small volume, recognises the importance of the personal equation and of local circumstances, and so lays down no hard-and-fast lines, though he keeps to those principles which lead to success. The chapters on soil-preparation, seed-sowing, and staking, are all dependable, and there are also valuable instructive notes on growing Sweet Peas for conservatory decoration, and in tubs for lawns and terraces. There is a chapter on the raising of new sorts, and another on exhibiting. Diseases, which in general are not troublesome, are passed in review, and it is pointed out how the creatures which in a garden are continually on the watch for something to eat may be diminished in numbers. There is a useful chapter on varieties of Sweet Peas; and here one could have wished that the author, instead of merely naming and giving the colour of new varieties, had also given an opinion regarding the merits, individual and comparative, of each. The history of the Sweet Pea is told in two chapters, one of which concerns itself with the Cupids, while the other traces its progress from the time the first English seedling flowered at Enfield in 1701 till the present day. In the second edition, which we hope Mr. Curtis will have to prepare, one or two inaccuracies will call for correction. Blue Sweet Peas were in existence in 1838, and much earlier, though Mrs. Loudon notes them in that year. Can the author be unaware that Mr. Eckford was engaged fixing a spot identical to Countess Spencer at the time the latter was exhibited, and that the stock he distributed was absolutely true? We imagine, too, that the author is mistaken in assuming that Mr. Malcolm uses wire-netting on which to train his Peas. Certainly in 1906 he used stout Pea-trainers. *B.*

NEW OR NOTEWORTHY PLANTS.

THE JULIANIACEÆ: A NEW FAMILY OF PLANTS.

IN a recent number of the *Philosophical Transactions of the Royal Society of London*, this proposed new order, or family, is very fully described and illustrated, and perhaps an exposition of its general and distinctive characters may interest some of the readers of the *Gardeners' Chronicle*.

Although it was only last year that the Julianiaceæ were defined, a member of the family was described, so far as imperfect material permitted, as long ago as 1843, and the author suggested that it might be the type of a new family.

So far as at present known, the genus Juliania consists of four species, all Mexican. They are tortuously branched, dicœcious, resinous shrubs or small trees, having alternate, unequally-pinnate leaves of three to eleven leaflets, and very similar to those of certain species of Rhus. The flowers are small, green, and the females are easily overlooked in the pollination stage. Both male inflorescence and individual male flowers are very much like those of the common Oak; but the inflorescence is usually more branched, and longer. A single, hairy, thin perianth, divided nearly to the base into five to seven acute segments, with as many stamens alternating with the segments, sufficiently describes the male flowers (fig. 3). But the female inflorescence and flower require a much fuller explanation. For purposes of comparison, the Sweet Chestnut and Beech may be brought in. In Juliania, as in the Chestnut and Beech, there are from two to four flowers enclosed in an involucre, the whole having the appearance of a single flower. Fig. 4 of our illustration represents two such inflorescences, about four times natural size. In each involucre of Juliania there are, at least in the early stage, four flowers seated side by side, not around a central axis. Usually the two central ones are perfectly developed—sometimes only one—and the two lateral are imperfectly formed and abortive. One of the inflorescences in fig. 4 has a single protruding, trifid style, denoting that only one flower had developed, though the cross section of the same shows four bodies. The other inflorescence in fig. 4 shows two perfect styles, and the longitudinal section an ovule in position. Fig. 5 is a longitudinal section, through a young involucre, much more enlarged, showing four flowers in section, with one ovule in each ovary. The styles of the two central flowers are cut off, whilst the two lateral ones are undeveloped. The length of one of these inflorescences at the stage represented is about half an inch, and as they are clustered in the axils of the closely-crowded leaves at the tips of the branches, they are easily overlooked. But these bodies do not consist entirely of involucre and flowers; only about one-fifth is involucre. This may be understood from figs. 4 and 5, and more easily perhaps from the ripe fruit of fig. 7. The flattened part below is the peduncle, not pedicel, as it was inadvertently termed in the *Philosophical Transactions*. Unlike the female flowers of the Cupuliferæ, with which Juliania has been compared, the female flowers have no floral envelope whatever, the flower being reduced to the pistil or ovule-bearing organ.

The ovule of Juliania is very different from any previously described, the funicle or stalk being the largest and most prominent part in the flowering stage, when the ovule is about one-twelfth of an inch in its greatest diameter. Fig. 6 represents one about six times natural size. The embryo or plantlet is formed in the upper lobe, beyond the slight constriction, and the rest of the body is an appendaged funicle, which nearly all disappears during the matura-

tion of the ovule into seed. Fig. 8 represents a seed, natural size, and 9 an enlarged embryo, very much like that of a bean. In both, too, the seed is exalbuminous.

The composite fruit is dry, and the tissues of the involucre exceedingly hard. Unlike the composite fruit of the Beech and Chestnut, it does not split to allow the seeds to escape, germination taking place through its open apex.

Of the three other species of Juliania two are very distinct and one very near J. adstringens, here illustrated. A Peruvian member of this family formerly referred to Juliania has been described as a separate genus under the name of Orthopterygium. *W. Botting Hemsley.*

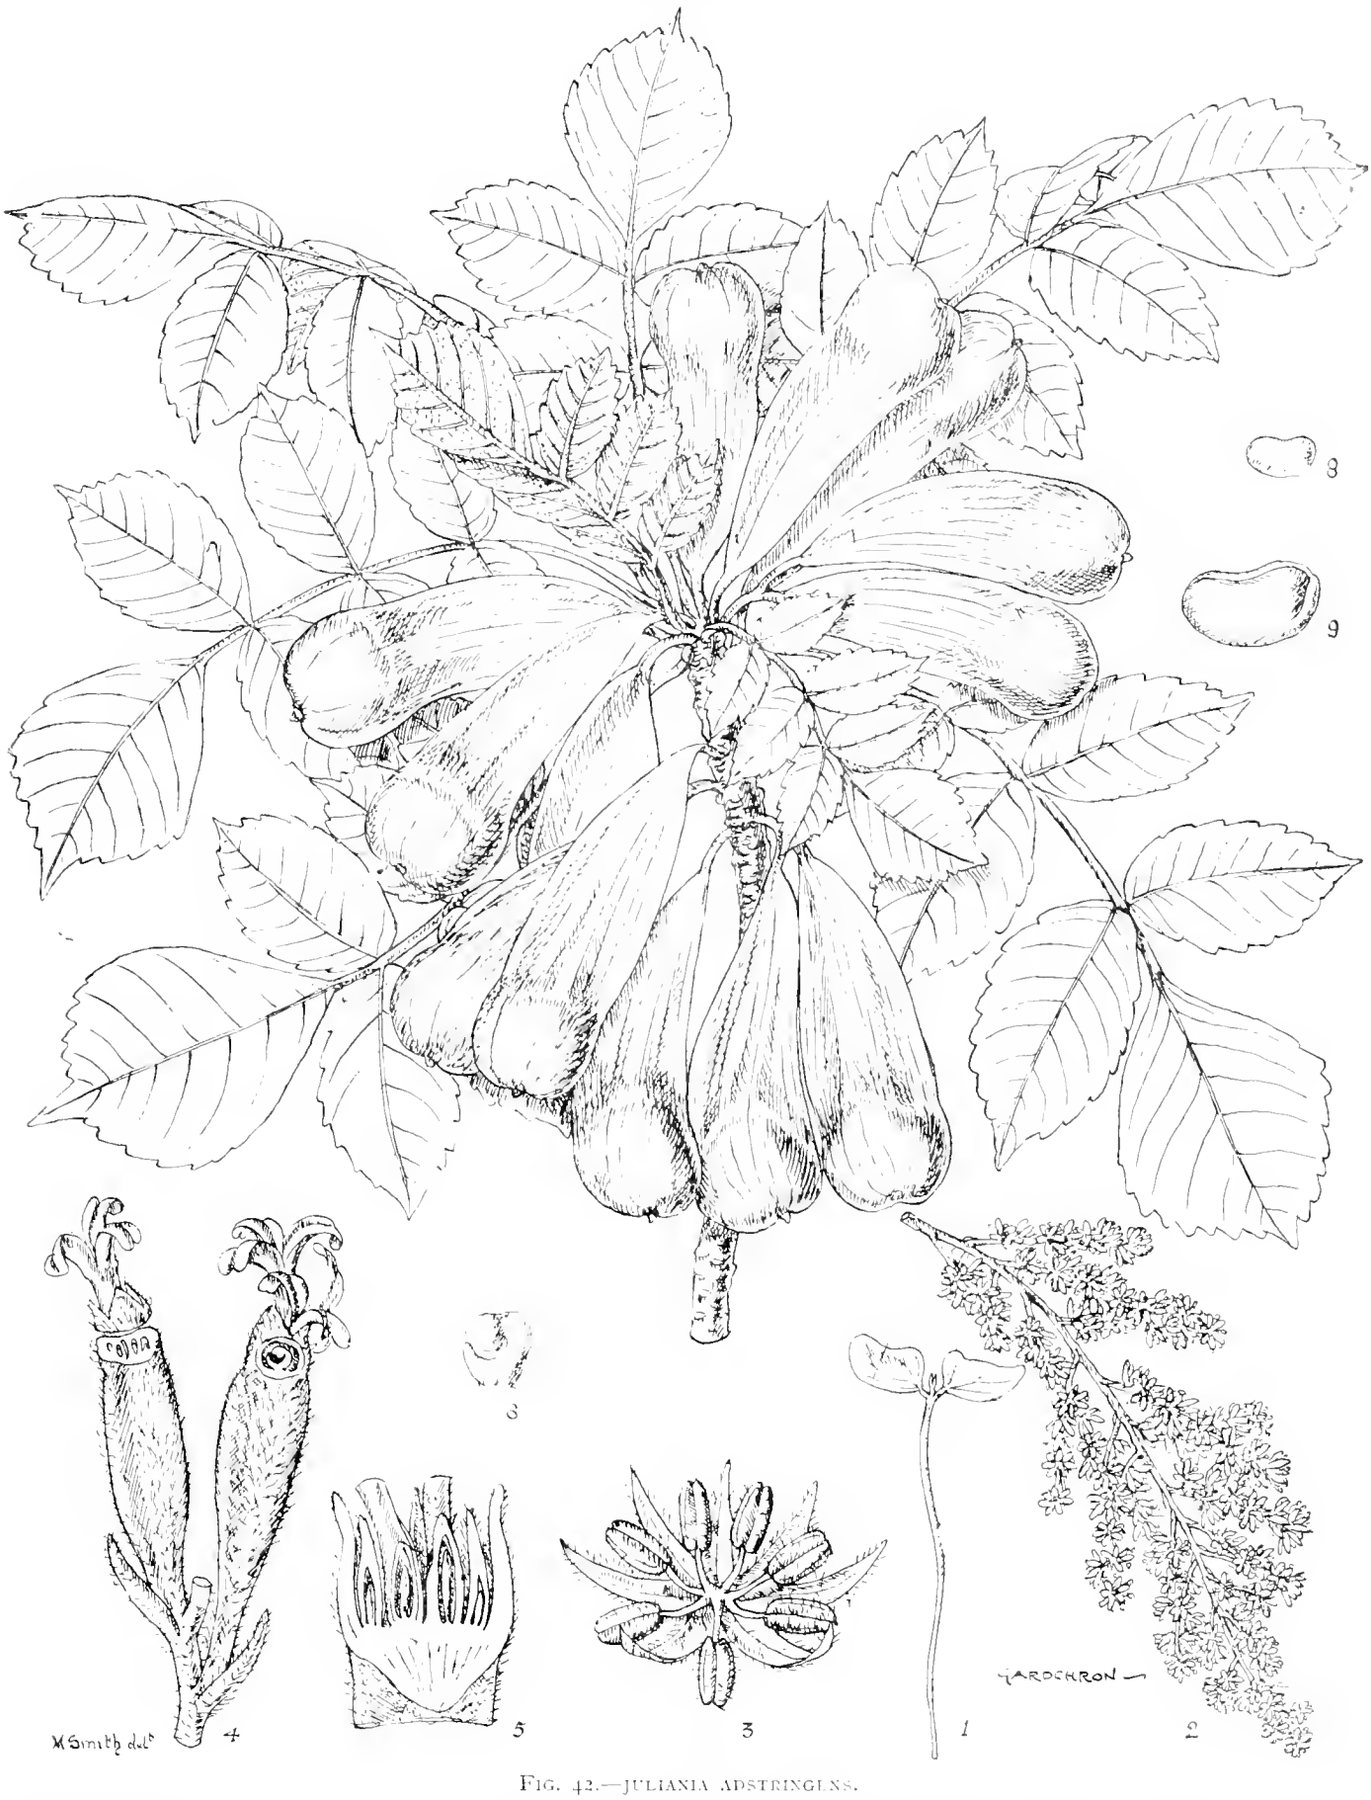

FIG. 42.—JULIANIA ADSTRINGENS.

1, a seedling, natural size; 2, a male inflorescence, × 2; 3, a male flower, about × 10; 4, two female inflorescences, consisting of two involucres each containing four more or less perfect flowers, one sectioned to show an ovule and the other the number of cavities, about × 4; 5, a longitudinal section through the flowers, showing portions of two perfect and two imperfect ones with one ovule in each ovary, much more enlarged; 6, a young ovule, about × 6; 7, a branch bearing ripe fruit, natural size; 8, a seed, natural size; 9, an embryo, about × 1½. (The dissections partly from the *Philosophical Transactions.*)

USES OF THE MOTOR IN HORTICULTURE.

(Continued from page 85.)

THE next matter for consideration is that where accelerated delivery is necessary, or where greater distances have to be covered.

If higher speeds are to be attained, in order to conform with the Government regulations concerning heavy motorcars, it is necessary that rubber tyres should be fitted; for although a 3-ton vehicle fitted with steel tyres is allowed to travel at eight miles per hour, as compared to 12 miles per hour with rubber tyres, it is generally allowed that the saving in the cost of tyre upkeep is more than lost in general damage consequent upon vibration set up by steel tyres.

There are many makes of the faster vehicle, and, with one or two exceptions, they are all fitted with internal-combustion engines to provide the motive power. The internal-combustion engine necessitates a great deal of complicated mechanism, through which the power is transmitted to the driving wheels; and as so many varieties of transmission gears are employed, it is impossible for anyone but the most experienced to form an opinion as to which vehicle is likely to give the best results, and even he must be well informed on the past performances of the particular make he has chosen. Therefore, it is of the utmost importance that great care should be taken in the choice of a vehicle. There are some makers willing to contract for the running costs and upkeep, and even if this is a little more expensive to the purchaser than doing it at his own risk, it is advisable to give these firms the preference, for it not only is an excellent testimonial for the reliability of their vehicles, but it will give the inexperienced time to master the detail of management, knowledge which otherwise, in all probability, would have to be expensively purchased.

A motor to carry from 3 to 4 tons, complete with body, cannot be bought under £700, and there is very little likelihood of this price being lowered in the immediate future.

The great advantages are in the speed and distance which these vehicles will travel without inconvenience. One hundred to 120 miles per day is not too much to expect from them, that is if straight running, such as depôt to depôt work, is all that they are required to do.

The following running costs are compiled from actual results —

TABLE No. I.

Annual running costs, for 3 to 4-ton petrol van, based on average journeys of 70 miles per day for 261 working days.

Depreciation, 20 per cent. on £700	£140	0	0
Petrol, at 2d. per mile for 18,270 miles	152	0	0
Tyres at 2d. per mile for 18,270 miles	152	0	0
Repairs, cleaning, &c., 10 per cent. on £700	70	0	0
Driver, 52 weeks at 35s.	91	0	0
Oil, waste, light, &c.	7	10	0
Sundries, insurance, &c.	25	0	0
	£637	10	0

This is equivalent to 8½d. per road mile, or 2d. per ton mile if loaded both ways, or 4d. per ton mile loaded only one way.

It will be noticed that only five days per week are allowed for running, and this leaves one day per week for cleaning and overhauling. Although there may be very little to do on some occasions, there will always be something that will be better for attention.

For 100 miles per day the cost would work out at something less than 8½d. per road mile, that is if the roads were good, because the only charges which would increase appreciably would be those for tyres and petrol, which increase in direct proportion to the mileage. The cost of tyres may not amount to as much as 2d. per mile, but as the tyre manufacturers will guarantee them at this figure, it is as well to be on the right side and adopt this as the correct amount.

The London motor omnibuses, which are of the same design in mechanism as the one now being dealt with, cost to run between 10d. and 11d. per road mile, and this includes the wages and salaries, change drivers, conductors, big rents for premises, and many other establishment charges which would not apply to a country service and for goods traffic; these facts should be borne in mind by anyone offering criticism. Another point is, the continual stopping and starting of the motorbus throws abnormal wear on to the tyres, wheels, and every part of the machinery, and this necessitates a night staff, who are continually overhauling the vehicles, in addition to the weekly or fortnightly thorough overhaul which they should have, even though many do not get it.

Now, granted that this vehicle will travel 100 to 120 miles in 9 to 10 hours, since its normal speed is 12 miles per hour, and it may be assumed that the owner will have a return load of at least 3 tons, then the following results are obtainable – A grower in the Midlands wishing to despatch his more valuable fruit or vegetables to the London market, from which he is 120 miles distant, may do this at a cost of exactly £1 per ton. If the motor left the Birmingham district at 5 p.m., it would arrive at Covent Garden by 3 a.m. the next morning in time for the earliest sales. The fruit would be fresher, and, having had fewer handlings, would be less liable to be bruised than by rail. The idea that a motor has excessive vibration is entirely wrong, more especially when the vehicle is loaded. The most delicate articles may be carried with perfect safety.

On such a lengthy journey as this it would be imperative to obtain return loads, and if the market gardener has nothing among his own requirements that would pay him to bring by road, by advertising, the necessary return load would soon be found. There is a great deal of traffic between London and Birmingham at rates between 25s. and 30s. per ton. Of course, this journey would occupy two days out and home.

For a single journey of 50 miles out loaded with 4 tons, and home with 2 tons, the cost would be 11s. 1d. per ton or 16's. 8s. if returning empty.

Every endeavour must be made to keep the mileage up to 350 per week, that is if the best results are to be obtained, but should the conditions warrant it, on a mileage of 180 per week the cost per road mile will only be 6d., for in this case the depreciation may be put down at 10 per cent. instead of 20 per cent., and the repair bill would be hardly worth taking into consideration, and certainly not more than a good driver could easily manage. The tyre and petrol account would also be correspondingly reduced, and the £25 allowed for sundries, such as extra assistance, might be saved.

The following table should make it clear what the running expenses should be to suit any conditions:—

Journey.	Cost per ton per mile.		Total cost per ton for whole journey.	
	d.		s.	d.
1. 120 miles' run, fully loaded	2	or	20	0
2. 50 miles loaded out, 50 miles empty return journey	4	,,	16	8
3 50 miles loaded out, 50 miles 2 tons' return load	2½	,,	11	1
4 35 miles loaded out, 35 miles empty return journey	4	,,	11	7
5 35 miles loaded out, 35 miles 2 tons' return load	2½	,,	7	7
6 15 miles loaded out, 15 miles empty return journey	3	,,	3	9
7 15 miles loaded out, 15 miles 2 tons' return load	2	,,	2	6

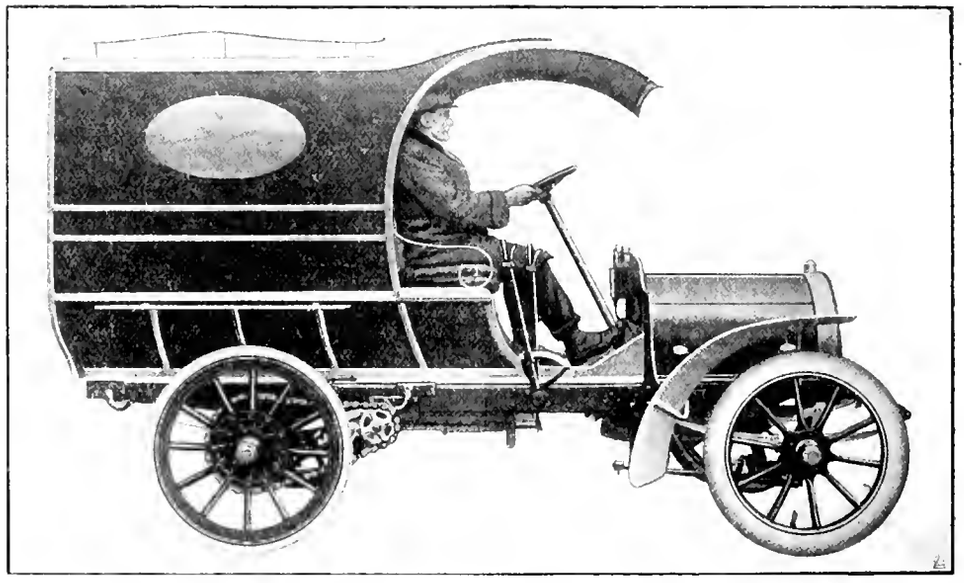

FIG. 43.—LIGHT DELIVERY-VAN, BUILT BY T. BLANCH, CHELSEA, TO CARRY 15 CWT.

It should be a simple matter from the above statistics to arrive at the cost per ton for any load for any distance, and this is the most important point to the owner.

Manufacturers invariably give the cost per ton mile, assuming the vehicle is loaded throughout the entire journey—this is very misleading, and might lead to serious miscalculation, especially to those who, having delivered their load, have nothing to bring back. *Hugh Miller, C.E., M.E.*

(To be continued.)

THE LEAF CURL OF THE PEACH AND NECTARINE.

THE supposed origin of this malady and the numerous remedies for the same have often been related, but the cure, apart from cultivation under glass, has not, in my experience, yet been discovered. In attempting to explain the cause of this annual visitant, I make no pretence of knowing its name or origin; or whether it exists summer and winter, as is sometimes stated, at the expense of the trees; or if, like the cuckoo, it is only a summer visitor. My experience during the past 15 years alone has given me some little

knowledge of the injury it causes to the trees, for during that period it has been an annual malady of the Peach and Nectarine at Lockinge. What with the making and planting of new borders, the application of supposed preventives and cures to the roots, branches, and foliage, everything has been tried, but with little or no effects. When looking at the small, sickly green leaves, one is inclined to believe that the seat of mischief is to be found at the roots; but having on many occasions examined the roots of the trees worst affected and found them in good condition, I have dismissed that belief from my mind. During the spring of 1906, when I expected to find "curl" as usual, there were slight frosts at Lockinge; lamps were kept burning by night and sometimes by day under a two-fold covering of warm netting, raising the temperature by 6° to 10°, and in spite of this precaution leaf curl was as bad as in any year in my experience, the puckering and crumpling of the thickened leaves being excessive. As in previous attacks, every affected leaf was removed and burned, which almost meant the stripping of the trees. My object was the destruction of what is described as the spore-bearing parts of the malady, and the trees were encouraged to make a second growth. This was very feeble, and for the rest of the year they appeared to be in a very poor plight, as was indicated by the small number of fruits on a wall 200 feet long and 10 to 15 feet high, namely, two dozen, and these inferior—an exceedingly poor return for the labour and other expenditure. The cultivation of Peach and Nectarine trees growing in this district on open walls is a hazardous undertaking. In the late part of the summer of 1906 it was determined to cover this wall with a glasshouse, and the planting of young and vigorous trees had to be considered. I was urged to replant the entire extent of the wall, but knowing the good conditions of the roots of the trees, I determined to afford them a chance. With the exception of two trees it was necessary to replace, a glass structure 7 feet wide was placed over all just as they stood. The trees were well cleaned, as usual, and as the flowering time approached, everyone was anxious as to what would happen. The leaves as fast as they developed were individually examined day by day, but the dreaded curl which for 15 years had made such havoc with the trees failed to appear—not one being affected; the growth and colour of the young wood and the foliage were very satisfactory, and the crops of Peaches and Nectarines equal to the best I had ever observed. The structure is unheated, and the fruits commence to ripen about the middle of the month of July, finishing the first week in November. The varieties are Hale's Early, Dymond, Crimson Galande, Condor, Bellegarde, Princess of Wales, Sea Eagle, Walburton's Admirable, and Late Admirable Peaches, and Cardinal, Early Rivers, and Lord Napier Nectarines. This scourge of the Peach when cultivated in the open, causes me no anxiety now, and the trees present a healthy appearance. The conclusion to be drawn from this satisfactory state of things—seeing that Peaches of fine quality are not inferior to any other kind of fruit and are in use for at least six months of the year—is that, in this part of Berkshire, the cheapest, most simple, and perfect cure for Peach blister and leaf curl is to plant the trees under glass.

"Medela," a recently-discovered preventive recommended by Mr. George Bunyard, I have not as yet tried, but I trust it will prove an efficient remedy for this destructive malady. *Wm. Fyfe, Lockinge Gardens, Wantage.*

FRUIT REGISTER.

LOCAL PLUMS: THE SYSTON AND PERSHORE.

Considerable interest attaches to these two Plums, as both are well known in their respective districts. They are readily increased from suckers, and they are especially prolific. Some time ago when the late Mr. Angus (formerly fruit foreman at Chiswick under Mr. Barron) was a resident in Leicester, I devoted several visits to an investigation of the fruits grown in the district around that town, including Syston; and the Plum, which is a favourite there, came in for examination. The result was that we decided it was quite distinct from its nearest relative, the Gisborne's, or Mrs. Gisborne. The subject was brought to my notice again recently, and as I could not place my hand on my original notes, I have endeavoured to obtain some local reliable evidence concerning the Syston Plum. Mr. John Harrison, of Messrs. Harrison & Sons, writes as follows: "The Syston Plum we have known for many years. It is commonly called, in this locality, the 'Syston native.' In many orchards in that village, which is five miles from Leicester, thousands of suckers can be dug out of the plantations and reared into trees which fruit the same as the parents. It has, therefore, been on its own roots for many years. The tree is rather a strong grower, with dark green leaves; the fruit is egg-shaped, with a thin skin of a deep rich yellow colour slightly spotted with crimson. The quality of the flesh is excellent, sweet, and juicy. We believe it has also been grown in some parts of the country as Mrs. Gisborne, and in such cases it is propagated in the usual way, being budded on Plum stocks. It is a rather uncertain bearer; in some seasons the trees break down with the crop, and several years may pass without any fruits. We consider it is tender in the bloom, though it blossoms freely. The Pershore Egg Plum is quite distinct, not so dark in colour, nor has it the same habit of growth; it is also very inferior in quality and slightly different in shape, being rather more pointed oval."

Mr. J. Lansdell, now of Worcester, but formerly a resident in Syston and a very keen observer, also obliges me with the following remarks: "The Syston Plum is distinct from the Pershore, but it is very like Gisborne's, though the fruit is much larger and better flavoured. It is a good grower and bears freely; it is also readily increased by suckers, which come into bearing nearly as early as the Pershore. The blossoms are not protected by the young foliage as those of the latter are, so they do not escape the spring frosts so well; and that, as far as I can see, is the only cause of the trees not bearing so regularly. The fruit is rather larger than Gisborne's, greenish-yellow when ripe, with a goodly number of crimson spots; it is very juicy, fairly rich in flavour, and a free-stone. It can be used for cooking when green, but is not so early as the Pershore. There are some varieties larger in size and of better flavour than others."

It may be added that the late Dr. Hogg's description of Gisborne's included the following remark: "Flesh yellow, firm, coarse-grained and not very juicy, briskly acid with a slight sweetness, and separating from the stone." The two letters here given and the above note confirm my former opinion that the Syston is really a distinct Plum and well worthy of being tried in other districts, but at present it appears in few trade lists.

The Pershore is widely known, and though an inferior Plum for ordinary purposes, is valued by jam makers, and owing to its wonderful cropping it has long proved of substantial value to Worcestershire growers. Whether it originated in Pershore or not the most careful enquiries have failed to ascertain, though it probably was a chance seedling which, being found to be easy of increase, rapidly spread over the whole county and gained the name of the "Worcestershire Weed." The Greengage Plum, which is extensively grown in some districts of Cambridgeshire, is quite distinct from the true Greengage, and affords another example of a local variety increased by suckers, and largely employed for commercial purposes. *R. Travis, Cambs.*

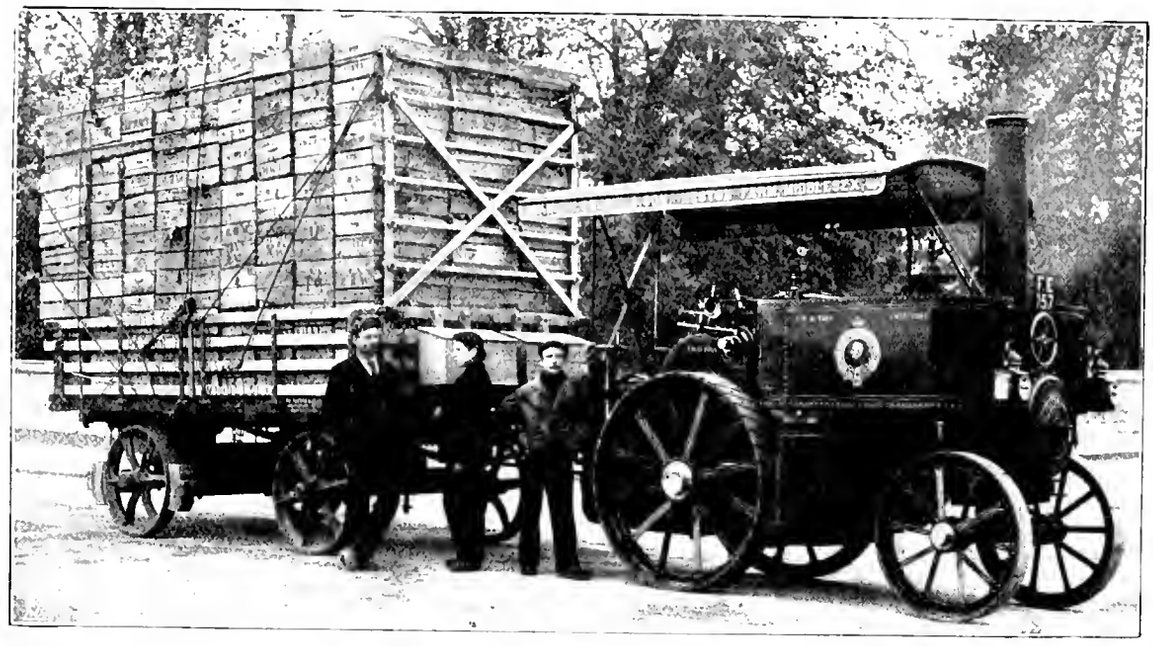

Fig. 44.—Messrs. W. J. Lobjoit and Son's "Wellington" steam tractor, with loaded trailer, bound for Covent Garden Market.

AMERICAN NOTES.

LARGE ROSE HOUSES.

THOUGH it sounds like treason to say anything against large glasshouses, practical growers are not all in accord with the builders of this class of structure. A span-roofed house 50 feet wide and some hundreds of feet long must of necessity be high at the ridge, and when to this are added low, solid beds instead of the old-time benches, 3 feet or more in height, the young Roses, when planted, are a long way from the glass, and do not start as freely as under the older system. Whether this late start is made up for by the use of grafted stock and ease of working wide houses remains to be seen, but more than one large grower, once partly converted to the large house theory, will, in the proposed additions this year, return to the more moderate size. Leaving the question of height, extreme length has its disadvantages independently of the difficulty of handling stock. In a Rose-house known to the writer, 800 feet long, there is one part where, directly air is put on, a kind of independent circuit is set up, and it is easy to see by the behaviour of the plants there that they do not relish the conditions. Green fly and mildew always attack at this point, and it is thus a kind of safety valve for the section men. In a house of moderate length these independent currents are broken up by partitions or otherwise, and, though this idea may seem far-fetched, there is more in it than at first appears.

FLOWERS AT FUNERALS.

MANY of the wreaths and floral designs used at funerals are very striking and original, our best florists having very bold and effective methods. We recently noted a fine piece of work at one of the cemeteries. It was a wreath about 4 feet across, the groundwork composed of Leucothoë sprays, and at the top a high purple bow of ribbon, flanked with immense bunches of double Violets and five plants of Cocos Weddelliana. Palls or blankets of Violets or mauve Orchids are also in favour; one sent out this week consisted of 40,000 Marie Louisa Violets closely wired on Asparagus plumosus. Much of the set design work is remarkable for the number and cost of flowers used rather than for beauty or grace, but there are notable exceptions even here.

AMERICAN CARNATION SOCIETY.

IN his address to the members of the American Carnation Society at Washington, on January 28-30, Mr. Fred H. Lemon, the society's President, proposed giving substantial prizes at the next meeting for Carnations in pots. Although so popular for cut flowers, these plants are very little grown in pots in America, and the proposal is a good one. President Lemon's ideas as to the exchange of new or improved varieties between English and American raisers, with a view of trying them out under the conditions existing in both countries, are also excellent. He warned commercial growers that the awards of the society are not to be considered evidence of reliability for commercial culture, but only reflect the judges' opinions of the flowers as shown; to know the capabilities of a variety as a commercial Carnation one must grow it or see it growing. There are other points in a good market variety besides colour, size, and stem, as many growers who have purchased novelties on the strength of the showing they make at exhibitions have found to their cost.

"Croppers."—In reading of American varieties as "croppers," English growers may be led to think the term eulogistic, but it is the reverse. In the quaint phraseology of the market growers, "cropper" is used to designate a variety that produces a crop of flowers and then "lets up" does not flower continuously, and is therefore not to be depended on. *H. R. K.*

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Masdevallias.—The species M. Veitchiana, M. ignea, M. Lindeni, M. Harryana, and their varieties are amongst the showiest of this genus which flower during the spring months. Since these plants completed their last season's growth they have been kept moderately dry at the roots, but now that renewed activity is apparent they will require more moisture, both at the roots and in the atmosphere. At this stage any plants that require re-potting or top-dressing may be given attention. If large specimens are desired, root-bound plants should be shifted into larger pots, with as little root disturbance as possible, while healthy plants that only require new surface material should have the old surface compost carefully picked out and replaced with new. When large specimens become bare in the centre they should be shaken out and broken up, and after cutting away all old growth and dead roots the pieces should be placed in pots just sufficiently large to accommodate them for one season. Pots or pans should be used as receptables for this section, and they should be filled two-thirds of their depth with rough drainage material. It is essential that the rooting medium be rough and open in character, as these plants dislike a close or water-logged compost. A mixture of good fibrous peat, or Osmunda fibre, two-thirds, and clean chopped sphagnum-moss one-third, with a liberal addition of crushed crocks and coarse silver sand, is the best potting compost. The compost should be made moderately firm, and the base of the plants kept a little below the rim of the pot. For some time after root disturbance, water must be afforded with extra care. An occasional sprinkling with a fine-rose can will suffice to keep the compost moist, and if on fine days the foliage is lightly sprayed over, and the plants kept shaded from bright sunshine, roots will soon be seen to extend freely into the new material. It is not often that a compartment is given up entirely to these plants, and the best has to be done with them in company with the Odontoglossums and the usual occupants of the cool house, but when a special structure is devoted to them they are, as a rule, much more satisfactory, as the requisite shade and moisture, so necessary for them, may be the more easily afforded.

The Chimæra section of Masdevallias.—Members of this interesting group may also be overhauled, affording new rooting material to such plants as require it. Teak-wood baskets are the best receptacles for this section, and they should be suspended from the roof rafters. Whilst a similar rooting medium to that advised above may be employed for these plants, no drainage must be used, owing to the flower-spikes being produced in a downward direction through the sides and bottom of the baskets. Plants of this section are much more satisfactory if accommodated with a little higher atmospheric temperature than the other species, and especially during the winter months. They are liable to attacks of red spider, therefore syringe the undersides of the foliage whenever the weather is favourable. Other insect pests that attack all Masdevallias are scale and thrips. The former may be got rid of by sponging, but the latter often prove more troublesome, especially the little yellow variety that attacks the flowers, quite ruining their appearance, and rendering a whole season's work futile if not kept in check.

PUBLIC PARKS AND GARDENS.

By JAMES WHITTON, Superintendent of the Parks and Open Spaces in the City of Glasgow.

Position for trees.—Continuing our consideration of playgrounds, if the space is of the type commonly met with, that is with a frontage to the street and the only one open, it may be possible to plant a few trees near the front line. Special care must be made to provide these with the most suitable soil, and only those species of tree should be selected that are most likely to thrive and grow to a sufficient size to create a sense of interest. Each tree must be provided with a strong and simple iron guard for protection against the small boy, whose hereditary instinct for climbing is sufficiently well known.

Gymnastics.—When the area is sufficient to admit of the erection of a set of gymnastic appliances the case requires greater consideration. Assuming that the site is similar in circumstances to the small one to which reference has been made, an arrangement which has been found satisfactory is to have one side for girls and the other for boys, so that the appliances best suited for each sex can be better arranged in regard to space. As there must be a caretaker in charge of such a place, his box or shelter should be placed at the back of the dividing line, so that he may have full observation of what is going on, although when the yard is fully utilised by the children he will require to move about amongst them to prevent the stronger monopolising the swings, &c., to the detriment of the younger and weaker children. There ought in these places to be a double shelter with sanitary conveniences. A good plan is to build one block, with the caretaker's room in the centre. Great care should be exercised in selecting the gymnastic appliances. When they were first started in Glasgow nearly every form in use was erected, but a series of accidents soon showed us which forms to avoid. The first to be discarded was the "see-saw." These—though fitted with recoil springs and india-rubber pads which mischievous boys cut or stole—were more productive of accident than any of the other appliances. The higher parallel bars and ladders followed next. So now the general equipment consists of swings in three sizes set in pairs, and the "giant's stride" or roundabout swings. For boys the "vaulting horse" and lower parallel bars and ladders are added. Under an attentive caretaker, accidents rarely occur now.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Potato sets for planting.—Very much depends on the manner these are treated preparatory to planting; they need every care that can be given them. If the tubers are placed together in heaps and are allowed to grow and produce sprouts that eventually get broken or rubbed off, much of their vitality and staying powers are thereby wasted. Sets of a medium size should be selected and arranged on trays or shelves, in the lightest position available, in a well-ventilated but frost-proof structure. Everything should be done to encourage a slow development of sturdy sprouts. The necessity for obtaining a change of "seed" cannot be too strongly recommended, as the results will unquestionably repay either the large or small grower. My experience has long since taught me that Irish or Scotch-grown tubers are to be preferred to any others. Continue to plant early varieties in pits and frames, and attend to those already in an advanced condition of growth by adding sufficient fresh compost to provide the new tubers with an ample covering, carrying out the work during the warmest part of the day.

Peas.—In warm localities, and on light soils, seeds of early varieties may be sown on south borders. Do not drop the seeds in the drill in a haphazard fashion, but place each seed at regular distances from each other and about as thick again as it is intended for the plants to be cultivated, thinning them to the required distance when the young plants have become about 2 inches in height. A common mistake with many gardeners is that of growing Peas too thickly, both between the rows and the plants. In cold districts, or in gardens where the soil is wet and retentive, it is much the better practice to sow the seed in boxes of medium depth, and to raise the plants under glass in an atmospheric temperature similar to that of a greenhouse, hardening them off for planting out when the weather is favourable. I have proved over and over again that by this system the results are far more satisfactory, and much annoyance is saved by having the plants under close control when quite young. Very early-sown Peas now growing in pots will need to have all the air possible. These should be grown quite cool and in a position exposed fully to the sunlight.

Broad Beans may now be sown in the open in double lines drawn at 4 feet apart, or plants may be raised under glass in boxes in the same way as Peas. The latter plan I strongly recommend,

as the plants when transplanted come into bearing much earlier than those sown in their permanent quarters. Plants growing in large pots should be placed on shelves near the glass, and be given a top-dressing when they are 3 inches in height.

Vegetable Marrows.—If these are produced under glass quite early in the season they are much appreciated, being grown quickly in a moderate degree of heat, the Marrows are of far better quality than those produced in the open during the summer. Seeds may be sown at the present time singly in small 60-pots, and raised in a heat of 55° to 60°. Pot them on when required, and either plant them out on mild hotbeds under portable frames or in large pots or boxes, and train the growths up the roof of an intermediate house. Good fruits may then be expected early in May. Moore's Cream, Pen-y-byd, Sutton's Perfection, and Prince Albert are all suitable varieties for this kind of treatment.

PLANTS UNDER GLASS.

By THOMAS LUSI, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

Codiæums (Crotons).—Cuttings of good clean growths should now be taken and inserted in a mixture of peat, loam, and sand in equal parts, each cutting being, together with its leaves, fastened to a small stake at the same time. The soil should be pressed firmly round the cutting; the pots placed in a brisk bottom heat, daily attention being given to make sure that the cuttings do not suffer from lack of moisture. Such of the plants as have been cut up to provide an increase of stock, if required for further use, should not be repotted along with the general stock of stove plants, but be kept in a sunny position until growth has freely started. They should then be shaken out of the soil to a considerable extent, and the roots reduced in quantity before repotting the plants. Treated in this manner they make splendid specimens, well furnished with foliage down to the rim of the pot. Care should be taken not to afford too much water at the root after repotting, but to syringe them overhead daily in bright weather and to keep up a temperature of 70° at night.

Dipladenias, now starting to grow, should be repotted in a mixture consisting of peat three-quarters, and light loam one-quarter, with a few small pieces of charcoal and silver sand in sufficient quantity to make the soil porous. Let the soil be made firm and compact, and do not use too large a pot, but one that is an inch larger all round than the old ball. Care should be taken not in any way to damage the tubers, and to apply water very sparingly for several weeks after the repotting. There is no difficulty in growing these plants if care is taken to keep them free from mealy bug. The best mode of training a plant of Dipladenia is to fix single strings at 6 inches apart under the roof of the stove and fasten one shoot to a string. Then if required for exhibition, place a balloon trellis in the pot and cut each string with its shoot attached and twine round the balloon. Dipladenias should be grown in full exposure to sunshine, and afforded a night temperature of not less than 70°.

Gloxinias.—As soon as any of the tubers show signs of a renewal of growth they should be shaken clean out of the spent soil and be repotted in a mixture of loam, leaf-soil, peat, and sand, taking care to provide good drainage in the pots, because Gloxinias require much water while in active growth. Water should, however, be very sparingly applied at first, a syringing of the plants overhead sufficing till leaf and root growth becomes active. Place the pots where they will obtain plenty of sunlight, with a night temperature about 65°.

Allamandas.—These plants should be cut back so as to make room for the season's fresh growth and be repotted. The plants will be benefited by being shaken out of the spent soil, and the ball of roots reduced in size. Allamandas being gross feeding plants, a few crushed bones, together with small lumps of charcoal, may be mixed in the compost of loam, leaf-soil, and sand. If an Allamanda plant is of large size, the root mass should be soaked in tepid water for an hour after repotting, and water be withheld until growth has made some progress.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Pineapples.—The plants raised from Queen suckers potted up at the end of the last summer being now well rooted, may be put into their fruiting pots 1 foot in diameter. Important details to be observed in potting are to drain the pots thoroughly, and to see that the balls of soil and root masses are moist; to pull away the small leaves at the bottom, so as to free the dormant roots of the plants before they are turned out of their pots; to make the compost firm by the aid of a rammer, and to place the plants deep enough in their pots to admit of the surface being covered with the new soil 2 inches deep. I make use of turfy loam that has been stacked for some months. It is by no means first rate, but poor and light, and after pulling it in pieces of a suitable size and shaking the fine particles out of it, I add dry soot and an artificial vine manure at the rate of a 7-inch pot full of each to a wheel-barrow load of the loam. As soon as the plants are potted, they are plunged at 2 feet apart in a bed having a heat of about 85°. The beds here are formed of leaf-soil that has not been changed—though added to—for many years, the heat being derived from hot-water pipes beneath. Until the days lengthen considerably, the temperature of the house at night ranges from 60° to 65°, with the usual increase by day.

Pineapple suckers.—As the suckers upon winter-fruiting plants of Smooth Cayenne, Charlotte Rothschild, and Black Jamaica, become sufficiently strong for removal, they should be potted in 7-inch pots and watered to settle the soil, air being admitted sparingly until the plants are well rooted; in other matters directions given for successional plants should be followed.

Figs in pots.—Trees that were started for providing an early crop of fruit should have the shoots stopped when the foliage is fully developed. This will confine the trees to suitable limits, and cause their fruits to swell freely. The shoots should be stopped at the fifth or sixth leaf. If the crop on a tree is heavier than it can properly mature, thin off some of the fruit while it is at an early stage, otherwise more fruit may fall subsequently than is desirable. A night temperature of 60° to 65° should be maintained when once the flowering stage is reached, and it may be increased by solar warmth to 85° by day if accompanied with careful ventilation. The pots are plunged in a warm bed at 70° to 75°, which temperature must be steadily maintained, otherwise a harmful check may result. Let the trees be syringed in the morning, and again early in the afternoon on fine days, in order to check the spread of red spider, and to provide the required atmospheric moisture, more or less in amount according to the prevailing state of the weather. Owing to the trees having a limited root run, the application of water, which should be tepid, likewise that of liquid manure, demands close attention. Top-dressings of turfy loam, mixed with bone meal and horse droppings, should be applied, and kept in position by a band of zinc or tin.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Peaches and Nectarines.—These trees having been detached from the walls, in order to retard the blooming period to as late a date as possible, must now be pruned and trained, as a very little mild weather will cause the buds to swell fast, and will render the work hazardous to the buds. In regard to the pruning, if the trees received suitable attention in the summer and autumn months, very little will now remain to be done, with the exception of the removal of any branch or shoot that can be spared, in order to avoid overcrowding them. One of the chief conditions of success in Peach and Nectarine culture on outside walls, is to have the wood thoroughly ripened, and this can only be brought about by allowing plenty of space between the shoots for the leaves to develop to their full size, so that the sun may reach the young wood. Careful attention to root-pruning when necessary also assists in retarding the trees. When the wood of the Peach and Nectarine is thoroughly ripened, the flowers become much stronger and hardier than those of overcrowded trees. If the trees were last year infested by red spider or scale, all ties and shreds should be removed and burnt forthwith, and the trees should be dressed with XL-All or some other kind of insecticide before the training is begun. Employ a fairly stiff painter's brush, in an upward direction only when dressing the shoots, or the buds are sure to be injured. Where the trees are clean, simply syringe them with quassia extract to which a handful of flowers of sulphur to each three gallons is added. If this be done after the training is finished, or just before the flowers open, it will generally carry them over the blooming period with safety. For training purposes, bast ties are better and cleaner than shreds, as they harbour no insects. Soft tarred twine or thin Willow twigs are best for fastening the main branches. Lay these in at equal distances apart, and the young shoots between them in such a manner as to give the trees a well-balanced appearance. The young shoots should generally be left their full length, care always being taken not to tie too tightly, as this is often a cause of canker. The shoots may be laid in at about 6 inches apart, or a little more in districts unfavourable to the Peach.

Protecting the trees.—When the training of the trees is completed, the means employed against frost should be got in readiness for use. Various materials are used for this purpose, and those who make use of temporary coverings should have the poles, &c., fixed in position, so that when protection is needed no time will be lost beyond fixing up the materials. The old stock of Frigo Domo, if that be used, should be examined and repaired, also the fixed wooden copings, so that everything may be in readiness. The stem and main branches at the base should also be protected with loosely made hay-bands or bracken, &c. When sharp frosts follow bright days, the latter causing the sap to rise quickly, the wood is liable to be frozen, and the consequent splitting of the bark and wood later results in disease.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

In the wild garden.—The first things required are to choose the plants, and the next the most natural manner of planting them. It hardly matters where, or what, the ground is, as something can always be found that will afford pleasing effects at given seasons. At the present time there are in bloom the Christmas Rose and other Hellebores, Winter Aconite, Snowdrops, and the yellow-flowered Jasmine, all of which appear more or less in perfection regardless of soil, position, or weather, and may be observed to advantage upon banks beneath trees, and in other positions. The picture is often less complete than it might be, because the number of each species planted is too limited. The Crocus, the Daffodil, Primrose, Anemone, Day Lily, Hemerocallis flava, H. fulva, H. aurantiaca, and H. Dumortieri, are now peeping through the soil; the Day Lilies to be bedecked in June and July with flowers of varied tints of orange yellow and tawny yellow. The wild garden should now have a general tidying up. The Bamboos will succeed in the wild garden, planted either on high or low ground, if provided with a little shelter from cold March winds. Many of the Spiræas are well suited for this garden when rocks and water are included. When placed behind a big piece of rock, near the water, the old Dundee Rambler Rose, with its annual growths of from 10 to 12 feet in length, forms a splendid object. Lenchtstern is another Rose that lasts long in flower, and has a good constitution. A good flowering shrub for spring, summer, and autumn is Prunus Pissardii, which has also striking crimson-coloured leaves. A fine companion shrub or half-tree is Acer Negundo foliis variegatis. Forget-me-nots, Honesty (Lunaria biennis), Canterbury Bells, and Anemones, may all be planted at this date, and when the plants are allowed to seed, the effect produced is natural and pleasing. Periwinkles (Vinca major and V. minor), St. John's Worts, Brooms, Gorse, Brambles (Rubus species), and Honeysuckles will all prove showy if the right positions be found for them.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents. *—The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

APPOINTMENTS FOR THE ENSUING WEEK.

THURSDAY, FEBRUARY 20—Linnean Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—39°.

ACTUAL TEMPERATURES:

LONDON: *Wednesday, February 12* (6 P.M.): Max. 52°; Min. 44°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London: *Thursday, February 13* (10 A.M.): Bar. 30·1; Temp. 41°; *Weather* Fair.

PROVINCES: *Wednesday, February 12* (6 P.M.): Max. 45° Guildford; Min 42° Hull.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—
Sale of Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY AND FRIDAY—
Hardy Border Plants and Bulbs, Lilies, Begonias, &c., at 12; 1,000 Roses at 1.30, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

WEDNESDAY—
Perennials, Begonias, Gladiolus, Lilies, &c., at 12; 532 cases Japanese Lilliums, Herbaceous Plants, &c., at 1; 3,600 Roses and Fruit Trees at 1.30; Azaleas, Rhododendrons, &c., at 5, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

FRIDAY—
Choice Cypripediums, Imported Orchids, 2,000 Odontoglossum crispum, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

"Quiet, Steady Progress."

The report of the Council of the Royal Horticultural Society for 1907, from which we published extracts in our last issue, commenced with the short, but significant, sentence: "Quiet, steady progress has again marked the past year." We are accustomed to read similar reassuring statements in most of the annual reports from various societies, and they are based on facts which are more or less convincing. But in the present instance the details of the report bear out the opening statement in a most satisfactory way. The total increase in the Fellowship during the year, allowing for the losses through death and resignation, amounted to 533, and the net increase in income to £904. The number of Fellows now amounts to 10,000, which is believed to be the largest membership of any British Royal Society.

In our issue for January 4, we referred to some of the principal items that now figure in the Society's report, and it is unnecessary to refer to them in any but the briefest terms on the present occasion. Amongst them are the completion of the Research Station at Wisley, the appointment of Mr. Chittenden as Director, the establishment of a school of horticulture, the publication of the report on the Genetics Conference, the Union of Horticultural Mutual Improvement Societies under the auspices of this Society, and other matters.

During the year 1907 the Society held 29 exhibitions, which were open on 35 days, and the arrangements for the present year appear to provide for at least an equal number. It is regrettable that the Council has again fixed meetings for days immediately following upon Bank Holidays, but at the annual general meeting on Tuesday last the Chairman promised that the subject should be given further consideration.

It is a satisfactory circumstance that the special societies are more and more attracted to the Royal Horticultural Hall for the purposes of their exhibitions, and the terms imposed upon such societies by the Council are certainly more liberal than formerly, although these terms are conditional upon the special societies undertaking to admit Fellows of the Royal Horticultural Society free of charge.

The Temple Show has increased in popularity to such an extent that its value to Fellows has suffered from this very cause, and complaints have been frequent that, owing to the excessive crush in the tents, it has become almost a matter of impossibility to make a critical inspection of the exhibits. Fellows should, therefore, feel specially grateful to the Council for giving to them a useful privilege on the second day of the show, as the hours between 7 A.M. and 12 A.M. are now set apart for Fellows only, the general or paying public not being admitted until after noon. This opportunity should be specially acceptable to business men on the one hand or to those serious horticulturists who may wish to look up specialities and note them with some degree of ease and comfort. How far Fellows may avail themselves of this special privilege remains to be seen. Possibly, for every one who goes to see, ten may go to be seen, and if that be so, the anticipated relief from the first day's customary pressure will be small. No similar condition as to admission will prevail at the Holland Park Show, where, thanks to the greater area at disposal, excessive crowding of Fellows and visitors has not existed.

The *personnel* of the respective committees of the Society remains almost the same as hitherto. It is a tribute to the excellent attendance of members generally and their faithful discharge of their duties that so few changes are now made. In the Fruit and Vegetable Committee one vacancy caused by death and one by resignation have been filled by gentlemen who are almost veteran horticulturists. On the Floral Committee the addition of a vice-chairman forms the sole alteration. In the Orchid Committee the changes affect but two or three persons.

The trials at Wisley this year will include, for the Floral Committee, herbaceous Phloxes, Cannas; outdoor, early-flowering and single Chrysanthemums, together with Cactus Dahlias, in order to test their garden decorative value, but varieties must have been put into commerce during the past three years and be of the true Cactus type. It is suggested that plants of these should be sent in by April to afford time to repot and grow them on, previously to planting out, and it is hoped that, in consequence, the results of this year's trials will be more conclusive than those of last year. The trials will be under the joint control of the Floral Committee and the National Dahlia Society.

The trials under the Fruit and Vegetable Committee will include Asparagus, Parsleys, Beets, Brussels Sprouts, Cabbages for spring sowings, and Potatos of new or established varieties. Also a trial of seed tubers grown in various localities, which means that English-grown tubers from diverse localities will be tested against Scotch-grown and Irish-grown tubers of similar varieties. The results of such a trial may be anticipated to point to the greater value of seed tubers obtained from localities where over ripening has not taken place. Some experiments in relation to fruit culture are also to be conducted, but these will require testing over a series of years. It is proposed to test the effect of various methods of planting trees, the results of pruning in the spring after planting, and of non-pruning; also of summer pruning, planting trees at different depths, and the effect on trees with their roots under growing grass as compared with others having their roots in cultivated soil. Such experiments, few as they are, should possess great interest for the garden students. For the present, these experiments will be limited to Apples, although other kinds of fruit will follow.

In addition to the examinations that are already conducted under the auspices of the Society, a new one is projected, suitable for youths under 19 years of age. It will follow the lines of the general examination, but will, we presume, be more elementary in character. It is both interesting and gratifying to note that the Society's examinations have resulted in raising the standard of knowledge, both scientific and practical, each successive year.

Such an increased measure of confidence as the Society has obtained from horticulturists and from the general public in recent years, necessarily imposes upon the Council a proportionate amount of responsibility. Mr. J. Gurney Fowler, who occupied the chair in the unavoidable and regretted absence of the President, Sir Trevor Lawrence, was able to remind the Fellows who attended the annual meeting on Tuesday last of the large amount of useful work performed in 1907, and, as Treasurer, he delivered his usual explicit statement of accounts, showing that, like prudent men, the Council is making provision for the future. Such a statement is eminently calculated to inspire the confidence of the Fellows.

Of the three retiring members of Council, all were re-elected, with the exception of the Earl of Tankerville, who was obliged to resign his position owing to distance from London. The vacancy thus caused was filled by the election of Mr. E. A. Bowles, M.A., who is already known to the Fellows in his capacity as a vice-chairman of the Scientific Committee.

The Chairman referred in sympathetic and appreciative terms to the great losses the Society has sustained during the year by the death of some of its principal supporters, among whom may be mentioned Sir Thomas Hanbury, K.C.V.O., Sir Frederick Wigan, Bart., Sir Michael Foster, F.R.S., and Dr. Masters, F.R.S.

We need not refer in greater detail to the proceedings on Tuesday last, a report of which appears on another page, but we merely voice the feelings of all our readers in expressing the hope that the indisposition which prevented Sir Trevor Lawrence from attending that meeting may be of a temporary character. We believe that Sir Trevor Lawrence has attended every annual meeting the Society has held during the past twenty-six years.

OUR SUPPLEMENTARY ILLUSTRATION to the present issue depicts the south side of the well-known church of St. Mary the Virgin, which forms so prominent a feature in the famous High Street, in Oxford. The old walls are draped with festoons of Virginian Creeper, which, like the Ivy, flourishes in the damp climate of Oxford, and lends a characteristic charm to many of its buildings. The church has always been closely associated with the University, and many of the colleges, as well as the Bodleian Library, are grouped around it, whilst the botanic garden is scarcely a quarter of a mile distant. The remarkable porch, with its twisted columns and symbolic ornament, is especially interesting, as its design formed one of the grounds of the impeachment of Archbishop Laud, in the reign of Charles the First. The tower and spire date from about 1400 A.D., the nave being built about 100 years afterwards. The spire was heavily decorated until about twenty years ago, when alarm was felt on account of its condition. It was restored by the well-known architect, Mr. T. G. JACKSON, R.A.

THE BOTANICAL MAGAZINE for February contains illustrations and descriptions of the following fine plants

REHMANNIA ANGULATA, *Hemsl.*, tab. 8177. The plant was introduced by Messrs. JAMES VEITCH & SONS, through their collector, Mr. E. H. WILSON. It is free-growing, and exhibits considerable variation in colour. Mr. WATSON, who adds a cultural note, suggests that it may be best treated as a tender biennial, or as a greenhouse subject. If planted out in the open in May, they reach 4 to 6 feet in height in July, when they are in bloom.

CODONOPSIS CONVOLVULACEA, *Kurz*, tab. 8178.—This plant belongs to the Campanulaceæ, and is a native of Eastern Asia. There seems some probability, however, that the source from which this particular batch of plants was derived lay further west, in the Himalayas.

PYRUS TSCHOWSKII, *Maxim*, tab. 8179.—This is a rare plant from Japan. The tree has grown well at Kew and flowered last spring better than it had done in previous years, probably owing to the hot summer of the preceding year. The plant was presented to Kew from the Arnold Arboretum by Professor SARGENT.

POTENTILLA CONCOLOR, *Rolfe*, tab. 8180.—This is a native of Yunnan in S.W. China, where it was discovered by the Abbé DELAVAY about twenty years ago, growing in calcareous soil at about 10,500 feet elevation. It resembles P. Griffithii, but differs from it in the larger leaflets and flowers. P. concolor is perhaps the finest yellow-flowered species known, and it is evidently quite hardy.

LARIX GRIFFITHII, *Hook fil*, tab. 8181.—This Larch was discovered in 1838 by GRIFFITH in Bhutan, and has been found in Nepal and Sikkim at elevations of from 6,000 to 10,000 feet. It does not appear to thrive well in the climate of Britain, and is especially apt to suffer from the attacks of the Larch blight.

THE NEW GAVIOTA PLUM.—Mr LUTHER BURBANK gives a brief description and a figure of this new Plum, raised by himself, in *The Rural Californian*. It is a cross between Americana and Japan, with probably half-a-dozen other varieties combined in it. The fruit is recommended as one of the best shipping varieties, and the tree is stated to be very resistant to disease of all kinds. The habit is less rampant but more productive than Formosa. Its season at Sebastopol (one of BURBANK's nurseries) is from July 15 to August 5. The fruit is deep reddish-purple, and the flesh is firm, pale yellow, fragrant, and sweet.

LINNEAN SOCIETY.—A meeting will be held on Thursday, February 20, at 8 p.m., when the following papers will be read:—"Experiments with wild species of tuber-bearing Solanums," by Mr. ARTHUR W. SUTTON, F.L.S.; "The life-history and larval habit of tiger beetles" (Cicindelæ), by Dr. V. E. SHELFORD; "On a possible case of mimicry in the common sole," by Dr. A. F. MASTERMAN, F.L.S. Exhibition: Mr. T. ERNEST WALTHAM, stereoscopic photographs of Alpine plants in natural colours

ROYAL BOTANIC SOCIETY.—Mr Geo. GORDON will deliver a lecture in the Royal Botanic Society's Gardens, Regent's Park, on the afternoon of February 20, the subject being "Gardens of Roses," which will be illustrated with lantern slides

APPOINTMENT. At a meeting of the directors of the Crystal Palace and District Cemetery Company, at Elmer's End Road, Beckenham, on the 7th inst., Mr F. COWELL was appointed to the post of Superintendent at a salary of £120 per annum. Mr. F. COWELL is 28 years of age, and during the past 11 years has been Gardener at the Lambeth Borough Council's Cemetery at Tooting

THE PALERMO BOTANIC GARDEN.—Owing to the splendid climate enjoyed by Sicily, the University Botanic Gardens are amongst the most beautiful in the world. Frost is almost unknown, and even the hot, dry, African wind gains enough moisture, during its passage across the Mediterranean, to render it harmless to vegetation. The garden is about 16 acres in extent, and it contains a very fine collection of plants growing in the open air. The Date Palm, Sabal princeps, Cocos plumosa, and Kentia Forsteriana, represent a few of the Palms to be found there, whilst Cycas revoluta attains to a height of 10 feet. The genus Ficus is represented by many species, some of which, e.g., Ficus magnoliodes, F. elastica, and F. rubiginosa, reach a large size. Strelitzia regiæ flourishes, and here and there are to be seen plants of that remarkable scrambler, Quisqualis indica, which climbs by means of the lower part of its leaf-stalks which are converted into woody hooks after the rest of the leaf has fallen away. Many plants familiar to those acquainted with the Canary Isles and the Cape also flourish here. There is also a fine collection of plants under glass, and recently buildings have been erected for purposes of photography, drawing, &c., and it is understood that the Director, M. BORZI, is about to build laboratories, which will render the gardens of great service to botanists desirous of working in a region so full of promise for investigations.

CULTIVATION OF FIGS IN CALIFORNIA.—The Smyrna Figs are known to require the aid of a gall insect for their successful pollination. The insect has passed its larval stage in another Fig, and as it is emerging from its chrysalis the stamens are just ripe, and the fly escapes into the air well dusted with pollen. When it enters the generation of Figs just opening, it does so in order to lay its eggs. It effects the pollination of the flowers inside the hollow receptacle, but ordinarily fails to lay its eggs successfully in this particular generation of Figs. The absence of the insect from California has, until recent years, made the cultivation of the Smyrna fruit impossible, but it appears now to have been successfully introduced into the country. It is expected that the Adriatic Figs, which do not require the services of the insect, and are those chiefly cultivated at the present time, will have to give place in the future to the finer Smyrna varieties

BIRMINGHAM PUBLIC PARKS.—The annual meeting of the Birmingham Park Workmen's Sick Society was held recently. The president and other officers were re-elected and the report, which recommended a dividend at the rate of 18s. per member, was adopted. During the evening Councillor DAVIS referred to the success of the society, and alluded to the services rendered by the hon. treasurer (Mr. W. H. MORTER). The CHAIRMAN then said he had been asked to make a presentation to Mr. W. H. MORTER, which had been subscribed by the whole of the parks employees. The presentation took the form of an electro tea service. Mr. W. H. MORTER, superintendent of the City Parks, acknowledged the gift.

PROPOSED CHAIR OF ENTOMOLOGY AT LIVERPOOL. The president and committee of the Liverpool School of Tropical Medicine are appealing for funds to found a Chair of tropical entomology and arachnology in the University in memory of the late Dr DUTTON, who lost his life in the course of his investigations on tropical disease. The movement has met with much local support, particularly by the Mayor of Chester, in his official capacity. It is understood that if the Dutton Memorial Chair is founded the first occupant will be Mr. A. NEWSTEAD, at present lecturer in entomology in the university. Mr. NEWSTEAD has often contributed to the columns of the *Gardeners' Chronicle*, and we are glad to think his work is likely to find appropriate recognition in Liverpool. As to the inherent importance of the subject of the proposed Chair, no one who is at all acquainted with the important part played by insects in spreading disease, as well as in directly producing it, can entertain any doubt; and it is greatly hoped that the appeal for funds for so important an object will meet with adequate support.

STATE FORESTS. Afforestation by the State is a subject which has occupied the attention of foresters in this country more and more in recent years. Messrs. CLIBRAN & SON, Altrincham, have published a pamphlet containing an article by Mr. FRASER STORY, which appeared in the *Manchester Guardian*, together with several letters which followed the publication of the article. The pamphlet contains many interesting particulars, and we believe that copies may be obtained gratis on application to Messrs. CLIBRAN.

TOBACCO IN THE PHILIPPINES.—Our American cousins are promoting the cultivation of tobacco in the Philippines, although as a staple crop it is said to be of less importance than when the islands were ruled by Spain. A bulletin on the cultivation of the plant by Mr. G. E. NESOM deals with the best methods of cultivation, and also with the pests that trouble its growth. The most important of these is perhaps the tobacco worm, which damages the leaves used for wrapping cigars. This is especially important in the Philippines, as practically all the best tobacco is grown with a view to using as wrappers, and any hole in the leaf, of course, spoils it for the purpose. An ingenious method of prevention is recommended. The Datura species, known in America as "Jimson" weeds, are common in the islands, and they are planted about amongst the tobacco, and poisoned honey or syrup is put in the tubular corolla. This attracts and kills the tobacco-worm moths, preventing them laying eggs on the crop. But good as the prevention doubtless is, hand picking is also necessary to destroy all the worms.

THE FRANCO-BRITISH EXHIBITION, 1908.—The following are the dates fixed for the temporary horticultural shows in the Exhibition grounds at Shepherd's Bush: June 2 and 3, July 16 and 17, and September 23 and 24. The Forestry Sub-committee solicit exhibits in the following classes:—Class 49. Appliances and processes used in arboriculture. Special instruments for gathering, preparing, testing and preserving seeds; tools and appliances used in tree culture and in the forest industries, tree-measuring instruments; preserving timber by creosote and other substances (examples and processes); prunings, good and bad, and their effects; malformation, curious growths of branch and root; damage by fungoid pests, insects, animals, storms, frost. Class 50. Products of the forest and of forest industries.—Collections of fruits, seeds, cones; specimens of indigenous forest products, home-grown timber cut into boards and transverse sections, giving age and conditions of growth; comparative exhibits of timber grown under various conditions; woods for cabinet work, building, staves, cricket bats; wooden gates and fencing (not painted or varnished); basket work, wattling; tan-bark, resinous substances. Class 51. Photographs, pictures, models.—Photographs of specimen trees and groups of trees, new or rare trees suitable for cultivation in the British Isles; also photographs showing operations in transplanting large trees, and various operations in forestry, such as thinning (before and after), coppicing, felling, removing timber and sawing; forest and nursery topography, maps, plans, books, charts showing imports of timber; of insects and fungi injurious to trees and their effects.

THE ELM BARK BEETLE AT LETCHWORTH.—A severe attack of the Elm bark beetle (Scolytus destructor) has occurred on the estate of the First Garden City, at Letchworth, Herts. About 50 Elms have been attacked on various parts of the estate, the species in each case being Ulmus campestris. The beetle was first noticed at work about three years ago, and since that time it has spread considerably. Several trees, apparently in perfect health twelve months ago, are now practically dead. In such cases, the holes made by the beetles can be seen all over the bark. Trees which have been freshly attacked this year show the presence of the beetle, even at a distance, by the leaves on certain branches turning yellow. Some of the trees, which are on sandy soil, show the effect of the beetles by losing their bark, which falls from the base of the trunk, but those on clay show no sign of their bark peeling. *Journal of the Board of Agriculture.*

SCHOOL GARDENS.—The report on Elementary School Gardens under the Essex Education Committee for 1906-07, which has recently been issued, is of great interest in connection with rural education. Forty-two gardens were inspected last summer, and the results were very satisfactory. Experience shows that the efficient teaching of gardening causes no deterioration of the general school work. On the contrary, it is found to induce a more intelligent interest in the ordinary school subjects by showing their practical utility in the processes of everyday life. The subjects profitably correlated with gardening are composition, arithmetic and mensuration, nature study, and drawing. Probably few changes introduced by the Board of Education into the curricula of elementary schools may be expected to be productive of better results than that of gardening, when it is taught by properly-qualified persons. At some of the Essex schools an excellent practice is followed in combining joint work on larger plots, together with the cultivation of small separate plots, by boys working either alone or in pairs.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

WHAT IS AN HERBACEOUS PERENNIAL?—The distinction between herbs, on the one hand, and shrubs and trees, on the other, rests upon two characters appertaining to the stems above ground the non-woody (herbaceous) or woody nature, and the duration of these. Although the two characters tend to point in the same direction, since the woody stem is for the most part the longer-lived, yet neither alone affords a basis for the absolute diagnosis of herbaceous perennials. If, as is common, we define these as plants living for several years and having stems that die down to the ground before each winter, then in winter our pastures must be bare as ploughed fields, our lawns miniature deserts, and our flower-beds patches of brown earth. Incidentally this example brings out the point that a distinction must be drawn between evergreen and deciduous perennial herbs. But the longevity of a shoot in our climate is decided largely by two factors: one is the cold winter, and the other is the production or non-production of flowers on the stem in question. Some stems die down because of winter; others capable of surviving this ordeal succumb immediately after flowering and fruiting. Will, therefore, a wider definition of a herb suffice, namely, that of a plant showing above ground only herbaceous stems which do not live for more than a year at most? Even this is not adequate. For, on the one hand, there are perennial grasses whose herbaceous shoots above ground live regularly for more than two years, and, on the other, there are little plants with prostrate woody stems creeping over the ground and emitting shorter, erect, herbaceous foliaged and flowering shoots that die within the year. From these latter plants to similar ones whose creeping stems are underground is a narrow step which is bridged both by casual individuals and by intermediate species. This merging of undershrub and herbaceous perennial is accomplished also in another direction, when the base of the erect main stem becomes more or less woody, as in the garden Wallflower, though the plant is mainly herbaceous. Again, treatment and climate complicate the question from a practical standpoint by locally making annuals into perennials and the reverse; examples of this are provided by the common Daisy, Mignonette, annual meadow grass, and Castor-oil plant. In framing rules for competitions at horticultural shows, while it is evident that plants with undubitably woody stems rising above the ground are ineligible, there should be a clear statement made as to whether plants with either only a woody tendency expressed in the stem or with a prostrate woody stem above ground are or are not excluded. Moreover, the conventional definition should indicate which of the following herbaceous perennials are admitted to competition: Herbs, with rhizomes woody or herbaceous, with bulbs, tubers, or corms, with above-ground shoots that live for one year or more, with evergreen or deciduous leaves, with succulent stems or succulent leaves, and with a climbing habit. *Percy Groom.*

PROTECTING FRUIT CROPS FROM FROST.—Whilst such protection (see p. 89) furnished to orchards or to lesser areas of trees in gardens may at short but critical times in the spring months be of supreme importance, several questions need to be answered satisfactorily. What is the prime cost of supplying furnaces or stoves? What is the cost of fuel to each one per night, and that of incidental labour per acre? One other is, How far does such effort at protection prove efficacious? This latter question can only be satisfactorily answered when a given area is experimented upon during spring frosts, and an equal area close by is not so treated. Unless these conditions exist, no real test of the merits of any effort at protection is furnished. In connection with the experiments referred to by an Evesham fruit grower, as told by Mr. W. E. Collinge, who had 21 stoves or fires per acre of fruit plantation, it is evident that these, if evenly distributed over the acre, must have been fully 100 feet apart. It is not difficult to imagine that within a few feet of its circumference, a stove or furnace in the open air, on a cold frosty night, can only make its warmth felt, and that at 50 feet from any two such stoves no possible influence on temperature could be exercised. For that reason, whilst it is possible that 9° of frost may have been fought successfully near each stove, no one can believe that such stove exercised any such power at remote distances. Were there a stove to every two rods, for instance, some general warmth might be felt, but that would necessitate some 80 stoves per acre. Then it is said that the smoke generated forms a smoke screen over the trees. If much smoke were generated, it is obvious that combustion must be slow, and consequently the heat given off would be small. You cannot have volumes of smoke and great heat at the same time. But unless the atmosphere was heavy and misty, thus causing the smoke generated to drift or hang low, this smoke protection would not be furnished. But our late spring frosts too often occur on clear, bright nights, when smoke in ever so great volume would ascend high and drift rapidly away, thus failing to form the desired overhanging shelter. But not frosts alone injure fruit blooms. A long succession of cloudy, gloomy weather, with very low temperature, or a succession of east winds, destroy the vitality of the pollen grains. However, experiments in the direction named may well be carried out, but under impartial control. If it were thus found possible to make fruit crops secure from frost, immense benefit would result. *A. D.*

THE RAINFALL IN IRELAND.—I see that the heaviest rainfall for 1907 mentioned in the *Gardeners' Chronicle*, which appeared on p. 73, was 55.39½ inches. It might perhaps be of interest to state that here it was 57.83 inches, rain having fallen on 218 days. June and August were the two wettest months, registering 6.62 and 6.41 inches respectively; and January the driest with 2.46. The heaviest fall on any one day was when 2.38 inches fell between the hours of 4 and 8 p.m. on September 10. *J. Smith, Mulroy Gardens, Co. Donegal.*

FRANCO-BRITISH EXHIBITION.—As you are probably aware, a large section in the forthcoming Franco-British Exhibition, which is to be opened in London next May, will be devoted to food stuffs and beverages, together with the processes of preparation in all their varied stages from the raw material to the finished article of consumption. The intimate relation this subject bears to the problem of our daily food supply alone places it in the front rank of those included in the great exhibition we are about to hold of the products and industries of two commercially allied nations. As chairman of the Alimentation Committee, I have been asked to write to you with the object of enlisting your sympathy and support in our endeavour to render this all-important section worthy of the British people. I would, therefore, beg you to accord us your invaluable assistance in making known the prominent position it will occupy. The French authorities are resolved to give a magnificent display in the alimentation section of the natural resources of their country, and it is hoped that our efforts to demonstrate the self-supporting character of the Empire will be equally conclusive. *Bessborough, Chairman, Alimentation Committee, February 5, 1908.*

HÆMANTHUS KATHERINÆ.—The photograph of a remarkably fine specimen of this species, reproduced as a supplement to the *Gardeners' Chronicle* for February 1, should induce lovers of bulbous plants not only to grow it, but to endeavour to procure other species from Africa; there are numbers of interesting Hæmanthi that are either no longer in cultivation, or have never been introduced. With regard to H. Katherinæ, I should like to point out two forms of it in cultivation, so distinct one from the other that I have a difficulty in believing them to be the same species. In the supplement above referred to, Mr. Raffill's photograph clearly shows two features: a somewhat narrow, pointed leaf, and upright habit of growth; and a dense spotting on both leaf stem and flower stalk or peduncle. The spotting, of a dark crimson-brown colour, is mentioned in all the descriptions of the species I have read. In the other form of H. Katherinæ to which I would draw attention, the leaf is wider in proportion, the point more obtuse, and the blade of the leaf has a more horizontal habit, giving the plant a distinctly different

appearance. In addition to this, the plant is absolutely unspotted. The figure in *Bot. Mag.*, t. 6778, gives a fairly good idea of this form. A tendency to a deciduous habit in the spotted form, not so observable in the other, may point to a hybrid origin, possibly to H. multiflorus, a species having a lateral peduncle, not a central one, as stated in error on p. 73. The flowers in both forms show little or no difference, to the best of my recollection. M. E. de Wildeman, in his monograph, *Les espèces du genre Haemanthus L. (sous-genre* Nerissa, *Salisb.)*, Bruxelles, 1903, draws attention to the improvements effected in this species by cultivation, but that, I imagine, cannot account for such radical differences, and we also know that both forms have been imported from Natal. Will some expert on this genus enlighten us? H. Kathermæ is stated to be the only representative of the subgenus Nerissa in South Africa. This fact, I think, adds to the interest of the question. *Walter E. Ledger, Wimbledon.*

SOCIETIES.

ROYAL HORTICULTURAL.

February 11.—This meeting, coinciding with the annual general meeting, was exceedingly well attended, and as a result the hall in Vincent Square was quite filled with exhibits of many kinds. Among them was a very fine display of species of Solanum and cultivated Potatos from Messrs. Sutton & Sons, Reading, which was awarded a Gold Medal. The same firm showed extensively in the floral section. Ferns were less numerous than at the last meeting, but the examples shown were wholly of hardy species and varieties. Carnations were much in evidence, and Cyclamens were very finely shown.

Orchids from Messrs. Sander & Co. (St. Albans), Charlesworth (Bradford), Cypher (Cheltenham), and others brought much beauty and variety into the exhibition.

The awards made to novelties consisted of four Awards of Merit, recommended by the Orchid Committee, and one Award of Merit by the Floral Committee, in the latter case the award being for a variety of Cyclamen shown by Messrs. Hugh Low & Co.

It is generally recognised that the new practice of displaying the plants certificated by the Floral Committee upon a table by themselves will tend greatly to the convenience of visitors, who have often heretofore found much difficulty in finding the novelties selected for awards. The table is situated in the recess where the Fruit Committee assembles for its deliberations.

Floral Committee.

Present: W. Marshall, Esq. (chairman), and Messrs. C. T. Druery, H. B. May, Jno. Green, T. W. Turner, C. J. Salter, W. Howe, Jno. Jennings, E. A. Bowles, R. W. Wallace, W. T. Ware, W. Bain, Chas. Dixon, J. Douglas, Chas. E. Pearson, W. Cuthbertson, A. Turner, H. J. Cutbush, W. P. Thomson, E. H. Jenkins, W. J. James, Jas. Hudson, Jas. Walker, Geo. Gordon, C. R. Fielder, R. Hooper Pearson, J. F. McLeod, and R. C. Notcutt.

Messrs. J. Veitch & Sons, Ltd., made a most interesting display of a miscellaneous character with plenty of colour in it. There were observed the little Azalea amœna "Hexe," certificated in 1906, a variety with larger, if not more brightly-coloured flowers than the type; the white-flowered Kalanchoe Dveri, a Central African plant, having corymbs of white flowers borne on stalks 2ft. high; finely developed plants of Coleus thyrsoideus, with two and three fine spikes on a plant; Cheiranthus kewensis, Primula kewensis, Gerbera Jamesonii, Freesia refracta alba; small plants of Shaddock abundantly flowered, and other species of Citrus. Among some freely-bloomed plants of Azalea indica were choice examples of Deutsche Perle, President, Oswald de Kerchove, Simon Mardner (a beautiful double flower of rose-pink tint), Vervaeneana (an old favourite), Madame Vermeesh (like Deutsche Perle, but with prettily-crimped petals and semi-double in regard to form), and Apollo (a resplendent crimson flower). Other plants shown by the firm consisted of a number of their strains of Primula sinensis, and all of them good. We may name Chelsea Favourite (light pink), Brilliant King (deep crimson), The Czar (a so-called blue of good shape), Magnifica, blue (of a lighter shade), and The Duchess (white, with a purplish rose-coloured zone around the yellow eye). Messrs. Veitch also made a fine display with Perpetual-flowering Carnations, American and English varieties as cut blooms, together with a few plants growing in pots. (Silver-Gilt Flora Medal.)

Messrs. H. Cannell & Sons, Swanley, Kent, exhibited fine Chinese Primula plants. The blooms were notable for their large size in general, and the clearness of the tints. Striking varieties were Swanley Giant, Cannell's Red, The Duchess, Giant Salmon (a very large, perfect flower), Queen Alexandra (a large flower, of regular form—white), Giant Purple, an equally good bloom in Mrs. G. F. Raphael, of a lilac tint, and several others. (Silver-Gilt Banksian Medal.)

Messrs. W. Cutbush & Son, Nurseries, Highgate and Barnet, showed cut blooms and plants of Carnations. We remarked the new winter-flowering variety, Glendale, a white flower with scarlet edge, very attractive looking; Dazzle, a scarlet, of moderate size; Mikado, a pink bloom, with thin edge of white, and white base to the florets, very distinct; Mr. W. T. Onwake, of a cheerful-looking rose-pink tint; Mrs. Robert Norman, an immense but rather loose, white flower; Helen M. Gould, also big, double, and pink in colour, blotched or flaked with crimson; and St. Louis, a fine scarlet variety. There were many more that visitors to the Hall have observed on several previous occasions. This firm had set up the accustomed bank of cork-covered boxes, and filled them with Narcissus, Rhododendrons, Heaths, Pernettyas, Helleborus niger, and Alpines. The other exhibits consisted of forced plants of Prunus triloba, Wistaria sinensis, Amelanchier, Lilacs in variety, Azalea indica, and Daphne indica rubra. (Silver Flora Medal.)

Messrs. J. Carter, High Holborn, London, showed several varieties of Primula sinensis, such as Holborn Crested, Princess May (light pink), Coral (a salmon-pink), Aurora (a pink, semi-double), and a fine white variety named King Edward.

Messrs. J. Peed & Son, West Norwood, S.E., showed Lachenalia pendula, a quantity of plants of Primula obconica, a few of P. kewensis, some Cacti, Aloes, Sedums, Sempervivums, Saxifrages, &c.

Messrs. Sutton & Sons, Reading, exhibited a fine set of P. sinensis, showing the highest culture, the flowers, large and of much substance, circular in form, with overlapping segments. Very attractive were Sutton's Giant Crimson, Giant Salmon Pink, Giant White, the new dark blue, The Czar, a beautiful variety, and Improved Reading Blue. The Duchess is a pink-eyed, white variety, with yellow colour only found in the depth of the throat. It is an acquisition in Primulas, and the same may be said of some of the Duchess hybrids that formed part of the exhibit. Some of these are chance crosses, others purposely crossed. They are distinct in several points. (Silver-Gilt Banksian Medal.)

A nice group of hardy Ferns was shown by Messrs. H. B. May & Sons, The Nurseries, Upper Edmonton, for which a Silver Flora Medal was awarded. The group was rich in Polystichum species and varieties, in Polypodium and Scolopendrium, among which last were many plumose forms.

Mr. W. H. Page, Tangley Nurseries, Hampton, made a large and striking exhibit of Lilium longiflorum, with six or more blooms on each pair of bulbs in a pot. L. speciosum rubrum, with a dozen blooms, and L. s. album the same. The centre foreground of the group was occupied with cut blooms of Carnations of the finest varieties lavishly displayed. The blooms of the pink Lawson were extremely fine. (Silver-Gilt Flora Medal.)

From Mr. G. Reuthe, the Foxhill Hardy Plant Nursery, Keston, came hardy plants, viz., Galanthus Elwesianus, G. byzantinus, Iris alata, I. sophonensis, Sedum species, Crocus atticus, a charming light-purple flowered species, C. Imperati præcox, bright in colour, Rhododendron cinnamomeum, R. Falconeri, R. decorum, and others not in bloom; also Berberis Bealii, with spikes of blooms just opening, cut blossoms of Camellia and Lomatia pinnatifolia, a handsome foliaged plant, of erect habit of growth.

Mr. Seward, of the Nurseries, Hanwell, Middlesex, showed very finely-grown Cyclamen giganteum, for the most part bearing flowers in large numbers, and of the largest size, on stalks of great strength. (Silver-Gilt Banksian Medal.)

From the St. George's Nursery Company, Hanwell, was exhibited another collection of fine Cyclamen plants to which a Bronze Flora Medal was awarded.

Messrs. Hugh Low & Co., Bush Hill Park, Middlesex, were large exhibitors of Carnations, both cut blooms and plants. There were remarked besides the now more common varieties, several newer, including Mrs. Burnett, Jessica, Winsor, Maudina—a charming purple flower, Princess of Wales, of the "Malmaison" class, and Beacon. The plants shown included one of a most floriferous variety named Oriflamme, two years old, which has carried and will still carry flowers to the number of 51. (Silver-Gilt Banksian Medal.)

Mr. H. Burnett, Carnation grower, Guernsey, showed a small number of plants of remarkably fine quality. Besides varieties of Enchantress, we remarked the very distinctly-coloured Marmion, Mrs. M. A. Patten, white with narrow crimson flakes; Lady Fellowes, bright rose, &c.

The Guildford Hardy Plant Co. (A. R. Upton, manager) exhibited species of Veronica and Ericas, including hardy species, such as E. carnea.

An imposing corner group was arranged by Messrs. R. & G. Cuthbert, Nurseries, Southgate, Middlesex. The group consisted of Magnolia speciosa 5 to 6 feet in height, and among these Japanese Acers, Pteris and other species of Ferns were placed. At the back, so as to mask the wall, tall Palms were placed, and in the "low ground" hardy Azalea made grand patches of orange and yellow colours, and taller plants of Staphylea colchica in bloom, with Prunus also in flower, were the more conspicuous ones, and the group was edged by miscellaneous Ferns. (Silver-Gilt Banksian Medal.)

Mr. R. E. Gill, nurseryman, 14, Market Street, Falmouth, exhibited trusses of various species of Rhododendrons taken from bushes growing in the open air. There was great variety in the colours of the flowers, and the exhibit gave a good idea of the floral beauty afforded by these and other species of Rhododendrons in this wild part of the country. The exhibits as a whole were enhanced by an extensive array of water-colour drawings of these plants and other varieties. (Silver Flora Medal.)

Messrs. Thomas Ware, Ltd., Feltham, exhibited Corydalis thalictrifolia, to show its usefulness thus early in the year. Sedums, Saxifrages, Helianthemums, hardy Cyclamens in bloom, Aubrietia aurea foliis var., Teucrium aureum, &c. (Bronze Flora Medal.)

Primula obconica, and a double form of it, besides a large number of very well bloomed Cyclamens, in all colours, were shown by E. A. Hambro, Esq., Hayes Place, Hayes, Kent (gr. Mr. J. Grandfield). These were exceedingly creditable specimens of good cultivation. (Silver Flora Medal.)

Herbert Chapman, Esq., Rye, Sussex, showed Freesia Chapmanii, a yellow-flowered hybrid, with blotch of orange, and another seedling of light yellow tint, almost cream-coloured. There were many other seedlings showing variations from the type. Also several rare Irises that bloom early, and are very dwarf, such as I. Kielagei Improved, I. Aspasia, a flower of brilliant blue and purple tints.

Mr. W. Palmer, Andover Nurseries, exhibited uncommon forms of Primula sinensis, in which there is a kind of doubling in the flower which takes the form of a central funnel in place of the usual "eye." It is not unpleasing, but the yellow-coloured eye is a more effective feature.

The Misses Hopkins, of "Mere" Gardens, Shepperton, made a display with rockery plants on a scale much larger than usual.

P. A. Molleno, Esq., M.P., Cape Town and Guildford, Surrey, showed about a dozen flowering shoots of Ericas, much withered and dried after their long journey from the Cape to this country. Among other exhibits rarely seen here were blooms of Proteas, some expanded, others "closed for the present."

Messrs. BARR & SONS, King Street, Covent Garden, London, showed flowers of various Narcissus, of sundry rock plants in some quantity, Helleborus pulchellus, H. purpureus superbus, H. fœtidus, H. colchicus, and one called Rosie, also specimens of Crocus Korolkowii, Galanthus, Adonis, &c.

Mr. L. R. RUSSELL, Richmond Nursery, Richmond, Surrey, exhibited largely berried Aucuba japonica vera, varieties of Eleagnus, both variegated and green-leaved Ivies, &c. (Bronze Flora Medal.)

Messrs. JOHN WATERER & SON, the American Nurseries, Bagshot, showed a group of rare and choice species of Conifers, including Pinus monicola, P. flexilis, Abies pungens, A. ajanensis, A. concolor, A. pungens glauca, &c.

AWARDS OF MERIT.

Cyclamen "Salmon King."—Messrs. HUGH LOW & Co. exhibited plants of this Cyclamen with large well-developed flowers of bright salmon-red shade. An Award of Merit was recommended the strain.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair); and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshay, F. J. Hanbury, H. Little, W. Boxall, Stuart Low, A. A. McBean, J. Cypher, A. Dye, F. M. Ogilvie, F. Sander, J. Charlesworth, W. Cobb, W. P. Bound, H. G. Alexander, W. H. White, F. J. Thorne, H. Ballantine, W. Bolton, C. H. Curtis, A. J. Foster, C. J. Lucas, R. Brooman-White, N. C. Cookson, Gurney Wilson, and G. F. Moore.

J. BRADSHAW, Esq., The Grange, Southgate, was awarded a Silver-Gilt Flora Medal for a group the centre of which contained a fine selection of white forms of Cattleya Trianaea. One specimen of the pure white C. Trianaea alba had eight flowers. C. T. Esmeralda, a new pure-white variety with light-pink front to the lip, C. T. Diana of a delicate-blush tint, and other white varieties, which in the aggregate bore over forty flowers, were included. The coloured forms had for their best C. T. The Premier and C. T. Mrs. de B. Crawshay, both grand flowers. With the white Cattleyas were a strong specimen of the reddish scarlet Odontioda Bradshawiæ, a finely-flowered Cymbidium grandiflorum and other Cymbidiums; a selection of hybrid Odontoglossums, and a grand lot of varieties of Lycaste Skinneri, the white forms and white-lipped varieties being specially good.

Messrs. SANDER & SON, St. Albans, were awarded a Silver Flora Medal for a group in which their fine strain of Cattleya Trianaea was well represented, the flowers being all of the broad-petalled type, with finely-developed lips. C. Trianaea Rex was a very fine form with blush-white sepals and petals and large violet-crimson lip; another form was similar to the fine C. T. eboracensis, but larger and with a deep-orange tube to the lip, which was rose-purple in front. Of the varieties of Cypripedium insigne the variety Shorthorn was distinct in colour and with peculiar reflexed and decurved petals; and porphyreum and Thompsonianum were distinct. A batch of hybrids of Epidendrum Wallisii and E. Endresii were at one end, and at the other a pan of the singular terrestrial Orchid Barlia longibracteata, resembling a Satyrium, with dense heads of greenish flowers, the cleft labellums being tinged with rose. Among the other species noted were the white Vanda Watsonii, Saccolabium bellinum, Oncidium Warscewiczii, and others not frequently seen.

Messrs. CHARLESWORTH & Co., Heaton, Bradford, secured a Silver Flora Medal for an excellent group, in which were many fine hybrids. Two varieties of Lælio-Cattleya luminosa bore very handsome and richly-coloured blooms: the favourite Cattleyas Empress Frederick and Octave Doin were well shown, and other showy forms well displayed. Of the new introductions Odontoglossum Lambeauianum var. Lyoth had finely-shaped flowers closely blotched with claret colour of a darker tint than in the fine variety Idol Lælio-Cattleya Sylvia (L.-C. Phœbe × L.-C. Ascania) of complex parentage, resulting in a yellow-tinted flower with pale-yellow lip, having a well-expanded rose front. Others noted as specially fine were Odontioda Bohnhoffiæ, with three spikes of reddish-crimson flowers; varieties of Odontoglossum Oi ol tum, Lycaste Balliæ, L. lasioglossa, some distinct forms of O. Pescatorei, good varieties of Cypripedium aureum, &c.

Baron Sir H. SCHRÖDER, The Dell, Egham (gr. Mr. Ballantine), was awarded a Silver Flora Medal for two magnificent specimens of the rare Odontoglossum coronarium brevifolium, the one with five and the other with four spikes of wax-like chestnut-brown and yellow flowers, the largest bearing twenty blooms. The plants have been many years at The Dell, and flower with increasing vigour.

Messrs. JAS. CYPHER & SONS, Cheltenham, obtained a Silver Flora Medal for an extensive and well-arranged group, the centre of which was of good white and coloured forms of Lælia anceps, with which were good Odontoglossum Hallii, O. crispum, O. Adrianæ, coloured Masdevallias, &c. Among the many fine Cypripediums were the very beautiful and equally rare C. Beekmannii in fine condition; the fine C. George Moore, varieties of C. Almos, C. aureum, C. Thompsonianum, and many others, including a selection of dark-tinted C. Fairrieanum. There were also a number of good Lycaste Skinneri, some excellent Cattleya Trianaea, Odontoglossum Vuylstekei of a very fine type, various Brasso-Cattleyas, including the bronzy-purple B.-C. Gipsy, and some interesting species.

Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. W. P. Bound), showed an interesting collection of hybrids raised at Gatton Park, two of the most remarkable securing Awards of Merit (see Awards). Among the others were a selection of Phaio-Calanthe Colmanii from white to pink in colour; the pretty little yellow Brasso-Lælia fladosa, a fine form of Odontoglossum Wilckeanum, and the superbly-coloured Spathoglottis Colmanii with a strong spike of large yellow flowers spotted and marked with ruby-red.

Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea, were voted a Silver Banksian Medal for an interesting group containing a great variety of their pretty Cypripedium Countess of Carnarvon (villosum × Euryades). The flowers showed great variation in form and colour, those with rose-purple and white dorsal sepals predominating. Some of the dark-purple spotted varieties resembled good C. Euryades closely. In the centre were three plants of the fragrant, white Platyclinis glumacea, the clear yellow Dendrobium Ophir, Lælio-Cattleya Nysa, varieties of Odontoglossum Pescatorei, Lycaste Skinneri, &c.

Messrs. MOORE, LTD., Rawdon, Leeds, were awarded a Silver Banksian Medal.

Messrs. STANLEY & Co., Southgate, secured a Silver Banksian Medal for a group of good Cattleya Trianaea, Cypripediums, &c. Among the Cypripediums, C. villosum Stanleyi was a large and good form, and another, named enecullatum virens, was a good yellow sh flower with a distinct green back to the dorsal sepal. Sophronitis grandiflora, Lælia flava and others were also shown.

Messrs. MOORE, LTD., Rawdon, Leeds, were awarded a Silver Banksian Medal for an interesting group in which were some very fine Cypripediums. C. Alcibiades superbum had a noble flower, with large, white dorsal sepal, spotted with purple, the rest of the flower somewhat resembling C. Beekmannii; C. Fairrieanum nigrum, a very pretty flower, with broad bands of blackish-purple on the dorsal sepal, the clear white-ground colour showing between; C. villosum, Moore's variety, had a very dark flower of fine size, the greater part of the dorsal sepal being dark chocolate-purple, suggesting an intermediate stage between C. villosum and C. Boxalli. Forms of C. Euryades aureum and others were also shown.

Messrs. HEATH & SONS, Cheltenham, were voted a Silver Banksian Medal for a group of Cypripediums, Cattleya Percivaliana, &c. Among the Cypripediums the showy C. Mrs. Wm. Mostyn, with its dark purple blotched dorsal sepal, C. Swinburnei magnificum, good forms of C. Mons de Curte, C. Mrs. Tautz, and some unnamed hybrids were noticed.

Messrs. HUGH LOW & Co., Enfield, were awarded a Silver Banksian Medal for a very effective group, the centre of which was composed of very finely-coloured varieties of Cattleya Percivaliana, the centre specimen having 26 flowers. With them were many pretty forms of Cattleya Trianaea, two sturdy plants of the fine Cypripedium Minos, Young's variety, two forms of the large and well-formed Cypripedium J. Seymour (callosum × Prewettii), two good dark Cypripedium Fairrieanum, a plant of the singular Cirrhopetalum ornatissimum, Dendrobium nobile virginale, &c.

Monsieur le Marquis DE WAVRIN, Chateau de Rousele, Ghent (gr. Mr. de Geeste), sent two very beautiful and distinct varieties of Cattleya Trianaea, the flowers of which, however, had been damaged by fog. The variety Princess Elisabeth of Belgium was a noble flower, with broad white sepals and petals slightly tinged with lilac; lip large, white with rose-purple front. A very peculiar feature is that there is barely a trace of yellow in the tube of the lip. The other was silver-white with a slight mauve marking on the lip, which had a yellow disc.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), showed Cypripedium Gratrixiæ giganteum, a variety which does much to redeem Gratrixiæ from being too near C. exul. The flower is large, of fine substance, yellow with a white upper part to the dorsal sepal, which is spotted with purple. The flower has a polished surface, and it is very distinct. Mr. Wellesley also showed Cypripedium William Mostyn (villosum × Mons de Curte), with circular white dorsal sepal spotted with claret colour, the spots getting smaller as they approach the margin. Petals and lip yellow, tinged with red-brown, the petals having fine dark lines.

Monsieur MERTENS, Mont St. Amand, Ghent, showed hybrid Odontoglossums and Cypripediums.

R. BROOMAN-WHITE, Esq., Arddarroch, Dumbartonshire, showed a very fine lot of cut spikes of excellent varieties of Odontoglossum crispum, a grand form of O. loochristiense, some Lælia anceps, Cattleya Trianaea, &c.

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, showed a pretty Lælio-Cattleya between C. Trianaea and L.-C. Phœbe, with orange-coloured flower tinged with rose, the front of the lip being claret colour.

AWARDS.

AWARD OF MERIT.

Cymbidium Lady Colman (eburneo-Lowianum × Tracyanum), from Sir JEREMIAH COLMAN, Bart., Gatton Park (gr. Mr. W. P. Bound).—A very beautiful Cymbidium, with flowers as large as those of C. Tracyanum. Sepals and petals greenish sulphur yellow, with fine dotted lines of purple. Lip white with distinct red markings. A very attractive flower.

Diacro-Cattleya Colmanæ (Diacrium bicornutum × Cattleya intermedia alba).—A very remarkable bigeneric hybrid, and a very worthy addition to our gardens. In habit the plant resembles Diacrium (Epidendrum) bicornutum, and the inflorescence is produced in the same way. The scape bore one flower and three buds, the expanded bloom being white, 3 inches across, and distinctly intermediate between the parents. Also from Sir JEREMIAH COLMAN, Bart.

Lycaste Skinneri Orion.—A fine flower with broad blush-white sepals, and rose petals with narrow white lines and tips. Lip pure white. From J. BRADSHAW, Esq.

Sophro-Cattleya Antiochus rubra (S.-C. Cleopatra × C. Warscewiczii), from Messrs. CHARLESWORTH & Co., Heaton Bradford.—A very handsome and brightly-coloured flower of a rich rose-purple tint with darker veining on the petals. Lip deep rose-purple. The flower is novel in colour, and the plant a very compact grower.

Fruit and Vegetable Committee.

Present: Mr. A. H. Pearson (in the chair); and Messrs. W. Bates, J. Willard, A. Dean, H. Parr, A. R. Allan, Geo. Keif, W. Fyfe, E. Beckett, P. D. Tuckett, J. Gibson, J. Vert, J. Jaques, J. Harrison, J. McIndoe, C. Foster, O. Thomas, G. Wythes, H. S. Rivers, R. Lye, C. G. A. Nix, and W. Bates.

Messrs. RIVERS & SONS, Sawbridgeworth, staged a collection of Orange trees in pots on the front of the platform at one end of the hall, which comprised varieties previously exhibited. The collection seemed to have most decorative value. (Silver Knightian Medal.)

Mr. W. ROUPELL sent from his garden at Roupell Park, S.E., excellent samples of Apples Newton Wonder, Smart's Prince Arthur,

Chelmsford Wonder, and Sandringham, being grown within five miles of Charing Cross. (Bronze Banksian Medal and Cultural Commendation.)

Mr. H. WIGLEY, Hasbridge, Gravesend, sent for tasting, a bottle of Morello Cherry Wine. The committee were not favourably impressed with it.

A rather handsome-looking Apple resembling Blenheim Pippin, and thought to be a natural seedling from it, came from Mr. J. CARTER, of Budleigh Court, Glastonbury. It was agreed to send a deputation to see the tree when fruiting next year.

Messrs. BARR & SONS, King Street, Covent Garden, London, sent a small collection of curled and variegated Kales, receiving a vote of thanks.

The chief exhibit before the committee, and indeed without exception the finest of its kind ever seen anywhere was one of 268 named varieties of Potatos, most of them very perfect and beautiful samples set up by Messrs. SUTTON & SONS, Reading. The collection occupied staging 70 feet in length, and were three baskets deep on the table, with two other rows of baskets elevated at the back. In the centre, on the table, was a large glass case containing many small tubers of diverse shapes and colours raised from Solanum species, or from the Commersoni Violet or Blue Giant, and specially Solanum tuberosum, the species to which has been attributed the race of edible Potato of to-day. Also Solanum etuberosum, which has given progeny the first year closely allied to that of the garden Potato, and which the Messrs. SUTTON hold to be the true parent and progenitor of our existing Potatos. The seedings of S. tuberosum were small and worthless, those of S. etuberosum of good size generally, and promising next autumn to produce high-class tubers. Into the origins and merits of the various species represented we cannot enter here. With respect to the varieties staged, of white ones, very fine were British Queen, Dalmeny Beauty, Empress of India, Goldfinder, Duchess of Buccleuch, Centenary, Peckover, Crofter, Reading Giant, Northern Star, Conquering Hero, Superlative, Monarch, Windsor Castle, Satisfaction, Abundance, Culdees Castle, Highlander, New King, Eldorado, Sutton's Triumph, Duchess of Cornwall, Arbitration, White Blossom, Sharpe's Victor, Factor, Up-to-Date, Prizewinner, and Ninety Fold. Notable coloured Kidneys were Blue Giant, Professor, Border Queen, Beauty of Hebron and King Edward VIIth. Finely-coloured "rounds" were Vicar of Laleham, The Dean, Eighty Fold, Ruby Queen, Crimson King, and Purple Perfection (purples), Reading Russet, Epicure, Herd Laddie, Lord Rosebery, Adirondack, and the Sutton Flourball (reds), whilst Lord Beaconsfield and The Yeoman were purple-blotched. Of the fir-apple type there were white, pink and red tubers, and also of similar shape the black-fleshed Congo or Zulu. (Gold Medal.)

ANNUAL MEETING.

FEBRUARY 11.—The 104th annual general meeting of the Fellows of this Society was held on the afternoon of the above date, at the Royal Horticultural Hall, Vincent Square.

Mr. J. Gurney Fowler, treasurer, presided, in the absence of the president, Sir Trevor Lawrence, Bart., K.C.V.O., V.M.H.

NEW FELLOWS.

The minutes of the annual general meeting of February 12, 1907, were duly confirmed, and 96 new members elected.

REPORT OF COUNCIL.

The Chairman, in moving the adoption of the report, which was taken as read, said he occupied that post owing to the indisposition of Sir Trevor Lawrence, whose doctor had said that he must on no account face the present inclement weather. It was the first time for 26 years that Sir Trevor had not filled the chair. (Cheers.) Turning to the report, he said it dealt fully with what had taken place during the year. One of the most interesting items was the fact that the Fellows had increased to 10,000. That was the object they had always had in view. On December 31 the number was 10,000, but since then 142 more had been elected. That was believed to be the highest number belonging to any British Royal Society. The next matter was the Temple show. It had been arranged that there should be a private view for Fellows only and for friends of Fellows possessing transferable tickets. On Wednesday, May 27, from 7 a.m. to noon, only these would be admitted. That would afford a much-wanted opportunity to Fellows to see the exhibits more or less at their ease. (Cheers.) That was a matter that had always been before the council. Alluding next to the accounts, he said they were very satisfactory. The net income of the society was £6,477, an increase of £657. The subscriptions had increased by £953, the dividends and interest by £236; the lettings of the hall had increased by £826. The lettings now amounted to £2,052, and the expenses to £1,699, leaving a balance of £400. Therefore the hall practically stood them in nothing, and they held their fortnightly shows for nothing in the way of rent. (Cheers.) The results of the Temple show were very satisfactory, the profits showing an increase of £169 over last year. Holland House show was not so successful, owing to the wet second day, but there was an increase of £20. There had been a large increase in the cost of the *Journal*. That was owing to the publication during the year of the report of the Genetic Conference and two volumes of the *Journal*. In addition to that, it was thought that, inasmuch as the *Journal* which was now in the press ought to have been published in the current year, it was wise to make a reserve to meet the expenses of publication. The amount set aside for that purpose was £750. Had that not been done, the cost of the *Journal* would be much more next time, and there might be three or four volumes to be issued during the current year. As to the balance-sheet, the society had invested £3,045 in 2½ per cent. National War Loan, and nearly £5,000 in 4 per cent. Canadian Pacific Railway Consolidated Debenture Stock. They had spent £1,427 on completing the laboratory at Wisley, and that was an expenditure which would not occur again. The depreciation fund now amounted to £979, that had been set aside during the past two years. It was arrived at by setting aside 5 per cent. on the cost of furnishing, 7½ per cent. on the cost of the Wisley glass-houses, 7½ per cent. on the plant and materials, and £120 per annum was set aside for the renewal of the roof of the hall when the architect should think it necessary. The architect considered that sum sufficient.

Sir John Llewellyn, Bart., seconded. He said prosperity had arrived at last, and it should not be forgotten that with a society like theirs prosperity brought responsibility. During the past year the society had taken a most important step fraught with great possibilities in connection with the laboratory at Wisley.

Mr. H. J. Elwes said he could not too much congratulate the Society on its financial condition; seeing it was so flourishing, he felt surprised that only £16 11s. 6d. had been spent on the library. He did not think that the necessity for a really first-class library was fully realised. He knew there were also trust funds, but he thought that the society could spare more than £16 11s. 6d. At present the library was in the charge of Mr. H. R. Hutchinson, one of the clerks. That gentleman always rendered him the most valuable assistance, and seemed to be able to find the most obscure papers at once. Their library should be under a librarian, and Mr. Hutchinson should be raised to that status. As to the *Journal*, he suggested that its general and scientific contents should be separated and published so. He preferred quality to quantity. Many of the old quarto *Transactions* contained far more valuable papers than the modern reports, and were more valuable to the society than those printed to-day. ("No!") With regard to the Masters' Memorial Fund a meeting had been held at which it was decided to establish Foundation Lectures on the Science of Horticulture. He did not know whether that meeting was known by the members of the society generally. He himself received a circular, but he said he would not subscribe to lectures. He believed Dr. Masters would rather have had the money spent on the library. If the feeling of the society favoured lectures, care should be taken as to what lectures were given. Any man could lecture on any given subject. That was not enough. A great deal of money was wasted—or spent—on lectures which were attended by very few people, and were apparently given because money was left for the purpose. Many such lectures might well be left alone. He hoped the matter would be ventilated.

Rev. J. H. Pemberton also alluded to the *Journal*, and said he should like to see it issued monthly. Such bulky volumes as at present issued were hard to digest.

Rev. G. H. Engleheart suggested that the staff of the society should render more assistance at the shows to those who were not prepared with trade apparatus. This might be done now that the society was so much better off. He had lost some exceedingly valuable flowers which he wished to take back for breeding purposes. Another important matter had reference to the awards. These were too easily gained, and their value should be raised. When he was on the council it was almost the annual injunction of the president and council to the various committees that they should be more sparing in bestowing the awards. The First-Class Certificate had been raised, and perhaps the Award of Merit had been sensibly raised, but he alluded to the giving of medals to the groups in the show. There seemed to be a feeling that almost every exhibit should have something given to it. That was a little undignified for such a society as theirs. He once met a gardener who was growing some fine plants, and he suggested that they should be taken to the Horticultural Society's meetings. The grower turned upon him as he spoke of the society's "pearls," and asked what distinction would it be to him when the society gave medals to a man for putting up a bank 50 feet long of herbaceous stuff or anything else. He thought they had rather cheapened their highest award, the Gold Medal. The highest awards should not be reserved solely for flowers produced under glass at the expenditure of so many tons of coal, but should also be given for productions of open-air gardens. He did not wish to do away with those beautiful things, but were not their awards given too much in that direction?

Mr. Arthur A. Sutton said he could hardly follow the last speaker in every detail, but he was sure the majority present would agree with what Mr. Engleheart said about the medals. They should not be given so lavishly.

Mr. R. W. Wallace (Colchester) said the sub-committees were most painstaking, and were not appreciated as they deserved to be. Many groups nowadays got only votes of thanks. The groups as a whole had advanced in quality, and that accounted for more medals being given.

Mr. Alex. Dean said the Fruit Committee took the greatest care in awarding the medals.

Mr. Engleheart said he was speaking only of the general tendency. Whatever might be the excellence of the exhibits, they should be constantly pushing up the standard of their awards, which should be made really worth obtaining.

Mr. Cuthbertson suggested that shows should not be held on the day following Bank Holidays. It was not fair to their men to ask them to work on holidays.

The Chairman, in replying, said they had had a most interesting discussion. As to the library, Mr. Elwes admitted that there were other funds devoted to the library. Speaking offhand, he could not say how much it was, but the Fellows had never, to his knowledge, complained that they could not obtain any particular book. If Mr. Elwes would say what useful books were missing, the Council would be very glad to obtain them. With regard to the *Journal*, it certainly had cost a good deal. He had already explained that, but if it were issued separately as suggested, that would add very considerably to the expense of publication. To have the *Journal* published monthly would be very nice, but the cost of postage of 10,000 copies every month would hardly justify the step. The *Journal* volumes were rather larger than they might have been, because fewer had been issued. They would endeavour to keep them to a more reasonable size. As to the "Masters'" Fund, that hardly came within the Society's business, although it had been taken up by prominent members of the Society. He did not know who suggested the lectures——

The Secretary (Rev. Mr. Wilks): I did!

The Chairman: I do not think Mr. Elwes suggested any other proposal.

Mr. Elwes said he firmly believed, from his discussions with the late Dr. Masters, that that gentleman would have wished anything that might be subscribed to be given to the library

The Chairman: The library is a "Lindley" library, and there would be very little memorial to Dr. Masters in it.

Mr. Elwes: The matter has never been brought before the members.

The Chairman: The secretary will explain. As to Mr. Engleheart's suggestion that more assistance should be given in the hall during shows, the Council would see if something could be done. Mr. Engleheart had raised the burning question of the awards. On the present occasion in the Floral Committee there were nine votes of thanks, and in the Orchid Committee there was one. He believed the awards were only given where they were justified. At any rate, this was the intention. As to the Bank Holidays, he felt if they could do away with the hardship spoken of, it would be a great advantage: but if their shows were to be held fortnightly, it could not be helped. The Council would see if some change could be made.

The Secretary, referring to the "Masters' Fund," said they had suffered a great loss in the death of Dr. Masters. At a meeting of the Scientific Committee it was brought forward that some memorial should be instituted, and he proposed that it should take the form of lectures. That proposition was submitted to the Council, and approved by them. A circular embodying that fact was sent out. A number of subscriptions had been received. Two of them were given conditionally. Mr. Elwes, they had heard, would not subscribe to lectures, which was the object for which subscriptions were asked; and another, who, he supposed, had heard of Mr. Elwes' condition, said he would not subscribe unless the subscription was retained for the object for which it was invited. (Laughter.) It was the desire of the Council and the Society to perpetuate the memory of Dr. Masters to future generations. The library was meant to perpetuate the name of Dr. Lindley. Other suggestions had been made, but he ventured to say that as lectures were put forth in the circular as the object of the subscriptions, the money should be devoted to that purpose.

Mr. Elwes said no opportunity had been given the members to express their opinion on the subject.

The report was adopted.

The officers of the Society were re-elected, with the exception that Mr. E. A. Bowles, M.A., F.L.S., succeeds the Earl of Tankerville as a member of the Council.

COMMONS AND FOOTPATHS PRESERVATION.

LORD EVERSLEY presided over the monthly meeting of the Commons and Footpaths Preservation Society held recently at 25, Victoria Street. It was reported by the chairman that a large number of members of Parliament had balloted for the society's Public Rights of Way Bill, and that Mr. R. Winfrey, M.P., had secured the fifteenth position. The Bill was set down for second reading for May 29, and the society had received promises of support from leading representatives of all parties. The main object of the Bill was to enable the provisions of the Prescription Act to be used in connection with the proof of highways and to simplify and cheapen litigation in footpath cases. It was decided to prepare a Bill to facilitate the regulation of rural commons, and Sir John Brunner consented to introduce the Bill on the society's behalf. It was pointed out that in many neighbourhoods commons formed the camping grounds of vagrants, who could not be satisfactorily dealt with without bye-laws made under a regulation scheme, and it was felt by the society that the time had arrived when privileges of compulsory regulation, similar to those enjoyed by the metropolis since 1866, with proper safeguards of the rights of the lord of the manor and commoners, should be extended to the whole of the country.

The solicitor reported that 11 Railway and Water Bills now before Parliament affected common lands and open spaces, the total area proposed to be absorbed exceeding 1,614 acres. Twenty-one other Bills affected Commons and rights of way. It was decided to press for the insertion in the Burnley Corporation, Monmouthshire County Council, and Pontypridd Waterworks Bills, under which large areas of common lands have been scheduled, of clauses to provide for the public right of access to the commons. It was also decided to support the local opposition to the Fishguard and Rosslare Railways and Harbours Bill, which seeks to absorb the whole of Goodwick Moor, and to oppose, if necessary, the London and Windsor Motor Roads, Tramroads and Tramways Bill, which would involve serious injury to Ravenscourt Park, Stamford Brook, Back Common, Chiswick, and other open spaces. The secretary (Mr. Lawrence W. Chubb) reported that the society was dealing with 120 cases of encroachment on commons or obstruction of rights of way, and that since the last meeting several footpaths had been re-opened as a result of its efforts. The society was stated to be arbitrating at the request of landowners and local authorities in three cases, and it was decided to oppose a scheme for the enclosure of Coopers Hill Common, Glos., a beautiful open space, 136 acres in extent.

CHESTER PAXTON.

UNDER the auspices of this society, Mr Robt. Newstead, A.L.S., &c., of the Liverpool University, delivered by special request a lecture entitled, "The Life History of the House Fly."

The subject-matter of Mr. Newstead's paper was based, for the most part, on the investigations that he had recently conducted in the city of Liverpool, with the view of ascertaining the nature and extent of the breeding places, habits and life-cycle of the common house fly, so that some measures may be devised for the destruction of this ubiquitous pest. The nature of the investigation was not given in detail, but it comprised the examination of over 300 ash-pits, about 40 stable middens, poultry yards, piggeries, and faecal matter lying in the courts and passages of the slums. The survey was restricted to five areas embracing in all 68 streets, special attention being given to those areas where infantile diarrhœa was most prevalent. A brief resumé of the evidence which has been adduced, by various authorities, bearing testimony to the importance of this as actual or potential carriers of disease in man was given. Temperature, Mr. Newstead said, had a marked effect upon the developmental stages of the fly: a sudden check from heat to cold will materially prolong any one of the stages. Eggs hatched out eight to twelve hours in a temperature of from 70° to 80° F., at a temperature of 60° F. in twelve hours, but at 45° F. they did not hatch until the third day, and then only when placed in a warmer atmosphere. The larvæ or maggots mature in the shortest period in fermenting materials in a temperature between 90° and 98° F., the complete cycle under the most favourable conditions being from 10 to 15 days, but a colder temperature prolonged the cycle to several weeks.

The principal breeding places in towns are middens containing horse manure only, middens containing spent hops, and ashpits containing fermenting materials such as old bedding, paper, straw, &c. They were also found breeding in all kinds of fermenting vegetable refuse, bedding in poultry pens and piggeries, temporary collections of manure, and human excreta when mixed with fermenting refuse. As a means of destroying the breeding places he recommended that all stable middens should be thoroughly emptied during the months of May to October, at intervals of not more than seven days, and ashpits at intervals of ten days. The application of Paris Green (poison) at the rate of 2 ozs. to 1 gallon of water to either stable manure or ashpit refuse will destroy 99 per cent. of the larvæ: and a 1 per cent of crude atoxyl (poison) in water will kill 100 per cent. of fly larvæ. Other measures were also recommended, and it was stated that the methods of control were under investigation. It was interesting to note that where fowls were kept they destroyed 75 per cent. of the fly maggots, there being a marked diminution of maggots in all cases where poultry were kept in stable yards.

The set of lantern slides which Mr. Newstead exhibited gave added interest to the lecture.

DEBATING SOCIETIES.

READING AND DISTRICT GARDENERS'.—One of the most interesting meetings in connection with this association was held recently, when Mr. T. J. Powell, of Park Place Gardens, Henley-on-Thames, gave a practical demonstration on the artistic arrangement of flowers. The first object lesson placed before the members was the decorating of a dinner table. The table had been laid to seat twelve persons complete with cutlery, glass, candelabras and silver vases. The central display consisted of an arch, around the pillars of which was trailed Asparagus Sprengeri, intermingled with sprays of Begonia Gloire de Lorraine. Under the arch was a splendid plant of Salmon Queen Cyclamen. At intervals were placed smaller arches decorated with similar foliage and flowers, the whole presenting a charming effect in pink. By request, Mr. Powell followed with the making of a lady's spray and gentleman's button-hole with Violets, also a small hand bouquet with the same flower. When these had been finished the time had arrived for closing the meeting, and it was decided that the meeting should be adjourned. Therefore the subject will be brought on again towards the latter part of this session, thus showing that practical demonstrations are exceedingly popular, and tend to make such societies a benefit to both old and young members of the gardening profession. Mr. H. Wilson, The Gardens, Lower Redlands, staged a collection of Apples, consisting of the following varieties: King of the Pippins, Golden Noble, Annie Elizabeth, Blenheim Pippin, Pott's Seedling, Warner's King, Bismarck, The Queen, &c. The association's Certificate of Cultural Merit was awarded to the exhibitor.

MANCHESTER HORTICULTURAL IMPROVEMENT SOCIETY.—At the fortnightly meeting, held on January 30, at the Memorial Hall, Albert Square, Mr. F. Robinson presided. Mr. H. J. Clayton, Wharfe Bank, Ilkeskelt, York, gave a lecture on "The Culture of Hardy Fruits." *A. M.*

HORSHAM HORTICULTURAL.—At the monthly meeting held on February 5, Mr. Edwin Neal, Gardener to J. Nix, Esq., Tilgate House, Crawley, gave a lecture on "Hints for Amateurs and Cottagers on Kitchen Gardening." The lecturer dealt lucidly with work to be done, and its performance during each month of the year; emphasising the need for deep cultivation, mulching, cleanliness, &c. Concluding his discourse, Mr. Neal gave a list of the best varieties of vegetables suitable to the soil of the district, and stated the best time for sowing. *G.*

CARDIFF GARDENERS'.—The fortnightly meeting of this society took place at the Philharmonic Restaurant on the 4th inst., Mr. H. R. Farmer presiding. The evening was devoted to "Questions" by the members. Many questions were put forward which created a good deal of interesting discussion. Amongst them were: "What are the reasons we do not get better results from the hardy fruit garden?" "Is there any remedy for suppressing the Cucumber spot?" "Summer or winter pruning of fruit trees?" "What is the cause of cracking in the berries of Foster's Seedling Grape?" "What is the best chemical to kill eel-worm?" These questions were discussed.

——— The annual dinner of the society took place in the same building on January 29. G. H. Batram, Esq., presided, and there were 50 members present. *R. T. W.*

STIRLING & DISTRICT HORTICULTURAL.—The usual monthly meeting of the association was held in Stirling on February 4. Mr. Geo. Petrie presided over a crowded attendance which had assembled to hear Mr. P. Murray Thomson, S.S.C., Edinburgh, deliver a lecture on "The Reproduction of Plants from Seed as explained by the Mendelian Theory." After giving some historical facts concerning Gregor Mendel's life and work, Mr. Thomson mentioned that the results of his experiments appeared in a paper published in 1865, which was afterwards lost to science till 1900. Its discovery led to a revival of interest in these matters; numerous experiments have been made with the object of testing what is now generally known as the Mendelian theory during the past six years. The lecturer showed, largely by means of diagrams, the results Mendel observed when experimenting with plants selected for that purpose. It was also pointed out that the old florists' theory, the mother or seed-bearing plant for habit, and the father or pollen-producing plant for colour, had been exploded. He urged all horticulturists to engage in a little experimental work, as thereby their labours would be made more interesting. Mr. Thomson will remove to England in March, and his departure will cause a great loss to Scottish horticulture.

THE WEATHER.

THE WEATHER IN WEST HERTS.

Week ending February 12.

A warm and dry week. All the days and nights during the past week have been warm for the time of year. On the warmest dry the temperature in the thermometer screen rose to 53°, and on the warmest night the exposed thermometer did not fall below 38°. Both of these readings were high for February. The ground is now warm, the temperature at 2 feet being 2° warmer, and at 1 foot deep 4° warmer, than is seasonable. There has been now no rain worth mentioning for five weeks, the total rainfall for that period amounting to only about a quarter of an inch. For three weeks there has been no measurable percolation through either of my soil gauges. The sun shone on an average for 1¼ hours a day, which is nearly half an hour a day short of the mean duration for this part of February. Light airs have alone prevailed during the week, the direction being throughout some westerly point of the compass. The mean amount of moisture in the air at 3 p.m. was six per cent. less than a seasonable quantity for that hour. *E. M., Berkhamsted, February 12, 1908.*

MARKETS.

COVENT GARDEN, *February 12.*

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

Cut Flowers, &c.: Average Wholesale Prices.

Trade still remains very quiet. Heavy supplies and slow demand. *E. J. Newbon, Covent Garden and St. Pancras, February 12, 1908.*

COVENT GARDEN FLOWER MARKET.

There is yet but little improvement in the trade for pot-plants. There is not much variety in the flowering plants; Azaleas are the most prominent, and well-flowered specimens sell fairly well. Cinerarias are very good. Chinese Primulas and Genistas are fairly well flowered. Begonia Gloire de Lorraine and the white variety have recovered from the effects of fog, and well-flowered plants are seen. The supply of Erica hyemalis is nearly over for the season. E. ovata, though not quite so bright as E. gracilis, is very pretty. E. melanthera is still very good. Marguerites are not quite so plentiful, and they are selling at better prices. Spiræa japonica is seen in well-flowered plants, also S. astilboides floribunda. A few good Liliums are seen, but they are now generally sold out early in the mornings. Solanums are still very good, but I find that supplies are nearly exhausted. Daffodils, Hyacinths, and Tulips in pots are good in quality, and over plentiful.

FOLIAGE PLANTS.

Kentias are still making higher prices, but there is not a large demand for them. Cocos Weddelliana, Geonoma gracilis, and Phœnix rupicola are very good in several sizes. Latanias and Asparagus tenuissimus and A. Sprengeri are good. Pandanus Veitchii was noted in various sized plants; those with the terminal leaves quite white sell well for use in ordinary decorations. There is but little trade for the coloured Dracænas at the present time, and Crotons (Codiæums) are not much in demand. Ficus elastica seems to have gone out of favour. Aralia Sieboldii and the variety Moseri do not make high prices, but there is a fair demand for them. Aspidistras are well supplied, and prices are lower than at the same period last year.

CUT FLOWERS.

Daffodils were not quite so plentiful at the end of last week, and blooms of best quality were cleared out at slightly advanced prices, but this week very large supplies have arrived. Those from English growers are certainly of the best quality, yet those from the Channel and the Scilly Islands arrive in very good condition. The varieties Horsfieldii, Sir Watkin, Golden Spur, and "Emperor," are of high quality. Narcissus Soleil d'Or, Paper White, and other varieties are abundant. Liliums were not quite so plentiful and prices advanced early in the week, but larger supplies were in again this morning. Eucharis and Gardenias are now scarce. White Azalea sells better now that good Chrysanthemums are scarce. Lily-of-the-Valley is over plentiful, and is being sold in the streets at very low prices. Good English Violets are seen, and large supplies arrive from France. Roses are uncertain. I find that best blooms of "Liberty," which were making 8s. per dozen, are now down to 6s. In Orchids I noted fine Cattleyas, Cœlogyne cristata, Odontoglossums, Dendrobium nobile and D. Wardianum and Cypripediums. Cut foliage is well supplied. Smilax and long trails of Asparagus are good. Croton leaves are the only really good bright-coloured foliage we have at the present time. Daffodil leaves make almost as much per bunch as is obtained for the blooms. *A. H., Covent Garden, February 12, 1908.*

SCHEDULES RECEIVED.

The National Sweet Pea Society will hold its eighth annual exhibition in the Royal Horticultural Hall, Vincent Square, Westminster, on Friday, July 24. The Society will also hold a Provincial Show in Dublin, on Wednesday, August 5.

Midland Counties Sweet Pea Society.—The schedule of this newly formed society is now to hand. We note that the Rt. Hon. The Earl of Plymouth is president of the Society, whilst among the vice-presidents and on the Floral Committee are many noted cultivators, including several names connected with the National Sweet Pea Society. The Society's first show is to be held in Wolverhampton on July 29, 1908, and the prizes offered amount to £70. In addition to this several medals will be awarded. The schedule contains the rules of the society and regulations for exhibition. Copies may be obtained on application to the hon. secretary, Mr. Owen F. Trott, 104, Waterloo Road, Wolverhampton.

TRADE NOTICE.

AMERICAN NURSERY COMPANY.

We are informed that the American Nursery Company has acquired all the real estate, property, business, and goodwill of F. & F. Nurseries, Springfield, N.J., The Bloodgood Nurseries, Flushing, L.I.—established 1790—Fredk. W. Kelsey, New York City, and the New Jersey and Long Island Nurseries. These concerns will hereafter be conducted as branches of the company under the same local management as heretofore. The officers of the company are: Fredk. W. Kelsey, president; William Flemer, vice-president and treasurer; Theodore Foulk, vice-president; and P. H. Goodsell, secretary.

REMARKS. Rhubarb from the Yorkshire district is now coming on the market in much better condition, and supplies are also being received from Essex. The sale for English Grapes remains good, but the supplies are shorter. Mandarine Oranges from Palermo are now of very fine quality, and are selling more freely. Teneriffe Tomatos are arriving in smaller quantities, and consequently prices have advanced. The last consignment of Winter Nelis Pears from the famous Rogue River Valley has arrived, and their condition suggests that they have been packed too long before being shipped. *P. L., Covent Garden, Wednesday, February 12, 1908.*

Obituary.

JOHN BOOTH.—We regret to announce the death of Hrn. John Booth, nurseryman, which occurred on Wednesday, February 5, at Berlin, in the 72nd year of his age. The deceased was well known in horticultural circles, and especially in connection with trees and shrubs, of which he had formerly a very extensive collection in his nursery near Hamburg. He was by birth an Englishman, but had for many years carried on the business of nurseryman in Germany.

Answers to Correspondents

AMERICAN GARDENING JOURNALS: *Hartop.* The *Garden Magazine*, published by Doubleday, Page & Co., 133-137, 16th Street, New York, at 15 cents per copy, per year $1; the *American Florist*, published at 1133 Broadway, New York, subscription, yearly, for Europe, $2 50. The chief office where subscriptions and correspondence must be addressed is at 324, Dearborn Street, Chicago; the *Weekly Florists' Review*, a journal for florists, seedsmen, and nurserymen, the Florists' Publishing Co., 530, Caxton Buildings, and 334, Dearborn Street, Chicago, subscription to England 2$ 50; *Horticulture*, published at 11, Hamilton Place, Boston, Mass., weekly, subscription to England, $2.

APPLE ORCHARD WASTE FRUITS: *E. W. B.* You could convert them into cider, which, when fermented, would afford alcohol by distillation. In Normandy a mild kind of spirit—popularly known as "brandy"—is extensively made from cider, selling at about 1 fr. per litre. The waste, if cleanly treated, would make jelly good enough for culinary uses. There are some books published on wine-making and on distillation that would afford the information you require. Enquire at the office of *Exchange and Mart.*

BOX HEDGE: *F. G. B.* The early part of April is the best time to cut a Box hedge. If drought or dry weather follows the operation, the plants should be moistened overhead daily by means of a syringe or garden hose. The soil should be loosened with a fork, and a top dressing of leaf-mould or old potting soil applied. About ten months ago the writer cut a Box hedge hard back, and it was treated as described above, with excellent results.

BRITISH GARDENERS' ASSOCIATION: *F. G.* We seem to gather from your letter that you are not a professional gardener, and if this is the case you will not be eligible for election to this society. But you can write to the secretary, Mr. J. Weathers, Talbot Villa, Talbot Road, Isleworth, Middlesex.

BRITISH GARDENERS IN THE UNITED STATES OF AMERICA: *W. W.* See a note on this subject in the issue of *Gardeners' Chronicle* for February 2, 1907, p. 80.

CARNATIONS: *E. H., S.* The plants are very badly infested with a fungous disease (Heterosporium). If the stock generally is in a condition similar to the specimens we have received, your best plan will be to destroy them by burning, and start afresh. If you obtain fresh plants it will be useful to spray them occasionally with sulphide of potassium as a preventive of disease.—*G. H.* The lower leaves are attacked by the Carnation black mould, Heterosporum echinulatum. Destroy diseased plants and syringe the rest with Bordeaux Mixture.

CARPET-BED DESIGNS: *A Reader.* A book of designs and how to plant them may be obtained of Messrs. H. Cannell & Sons, The Nursery, Swanley, Kent.

COCCUS ON FOREST TREES: *Subscriber.* The only thing to be done is to spray the trees with an insecticide. It will be an easy matter to cleanse the trunks in this manner, but if the trees are of large size it will be very difficult to get the spray on to the uppermost branches.

COOL GREENHOUSE: *M. E. C.* You neglect to inform us what species of plants are contained in the house. If the collection comprises miscellaneous species there will be some of more or less degree of tenderness. In any case, it is necessary to have means at your disposal to repel frost, and therefore it would be unsafe to entirely discontinue the use of fire-heat during this or next month.

CUPRESSUS AND PICEA: *W. B.* The trees are suffering from root-rot caused by a fungus. Remove the soil for some distance round the roots of the remaining trees, sprinkle the roots with quicklime, then fill up again. The surrounding soil should also have quicklime lightly pricked in to destroy the white spawn present.

GERANIUM: *G. H.* There is no organic disease, but plentiful traces of insects.

HORTICULTURAL COLLEGES: *Miss Young.* You might write to the principals at the Horticultural College, Swanley, Kent; "Lady Warwick" Hostel, Studley Royal, Warwick; Edinburgh School of Gardening for Women, Murrayfield, Midlothian; Royal Botanic Society's School of Gardening, Regent's Park, London; and the Reading College, Berkshire.

IMPORTATION OF ODONTOGLOSSUMS: *Odonto.* The fresh-collected plants are conveyed along the river Magdalena to Baranquilla and Savanilla, from whence they are shipped to Europe.

LAWS FOR MARKET GARDENERS: *C. B. L.* We believe there is at present no book which deals with this subject, but you may possibly get the information you require from our issues of November 3 and November 10, 1906.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: *Glasgow.* Cœlogyne cristata.—*Rev. I.* Goldfussia (Strobilanthes) isophylla; 2, Peperomia Verschaffeltii; 3, Chlorophyton variegatum; 4, Stenotaphrum glabrum variegatum; 5, Abutilon Savitzii.—*T. T.* Oncidium pubes.—*Correspondent Garrya.* Garrya elliptica.

PEAT: *J. S. D.* Consult our advertisement columns, or insert a small advertisement yourself stating that you are prepared to buy large quantities.

PELARGONIUMS: *Correspondent.* We suspect that the failure has been caused by planting the cuttings too deeply, and the grub has entered the stem after the commencement of decay.

PLANTS FOR WALL-TOP: *R. R.* With so small a cavity for containing soil, you must give unremitting care to the plants during their growing season and in hot weather, otherwise failure will ensue. Six suitable plants would be as follows: Onosma taurica (yellow), Saxifraga, Cotyledon pyramidalis (white, pink-spotted flowers), Campanula muralis (pale blue), Achillea umbellata (white), Aubrietia "Dr. Mules" (deep violet), and Iberis sempervirens (white). Dianthus deltoides (rose), Corydalis lutea (yellow), and Zauschneria californica (scarlet) would also be suitable. We do not think Ferns would be of much service to you.

SPRAYING FOR PLUM APHIS: *L. F.* The earlier spraying is commenced the better is the chance of keeping the pest named in check, and the chief difficulty is to provide a mixture that is strong enough to destroy the insects, and at the same time one that will not injure the blossoms or tender young leaves as they expand from the buds. Well-diluted quassia and soft soap is usually safe, but it is not so effectual as petroleum or kerosene emulsions, though greater care is needed both in the preparation and application of the latter liquid. Half a pound of soft soap can be boiled in a gallon of water, and two gallons of petroleum added slowly and well stirred in while hot, using a strong syringe to assist in the mixing. This is important, and should be continued until it is seen that a thorough emulsion has been formed. Diluted with about 50 gallons of water, this is commonly safe enough for application to Plum foliage; but it is wise to err on the side of a little extra dilution and repeat the dressings several times at intervals of a day or two. Much depends upon the condition of the foliage; in mild, moist weather the young leaves are often extremely tender. Varieties differ also in their liability to injury from such mixtures, and it is always wise to test the effects on a small scale before proceeding to a general or extensive spraying. The *Book of Garden Pests*, reviewed on p. 83 in last week's issue, gives further information on this and kindred subjects.

SWEET POTATO (*Batatas edulis*): *An Old Reader.* This is propagated by tubers set out at distances of 1½ feet apart, and preferably on ridges, 1 to 2 feet above the general level, so as to afford greater depth of soil and warmth than could be obtained by surface planting. The thick end of the tuber should be planted downwards, and the top end, which is quite small, should be only an inch or two beneath the surface. Plant the tubers in a warm position. The stems and foliage are the better for being supported on tall Pea sticks. If much increase of stock is required, layer the stems.

THE SYSTON, PERSHORE, AND GISBORNE'S PLUMS: *L. F., Ashby-de-la-Zouch.* When these Plums are obtained true to name they will be found to be distinct, though there is a close resemblance between the first and the last (which is also sometimes seen under the name Mrs. Gisborne). There has been considerable confusion in the naming of Plums in some districts, and in this case we have seen all three under different names. It is easy to distinguish the Pershore by the shape of the fruit, which has gained it the local title of "Egg Plum." The Syston is superior to Gisborne's both in the size and flavour of the fruit, and is readily increased by suckers. See also note on p. 101.

TULIPS: *Jeannot.* Your Tulips are attacked by the "Tulip mould," Botrytis parasitica, Cav. This is one of the most serious pests amongst Tulips. The bulbs are covered inside the outer brown sheath with the spawn of a fungus, which forms small grain-like bodies (sclerotia), which produce as soon as brought into the houses for forcing a greyish mould, which rapidly destroys the bulb. Hitherto no remedy has proved efficient and the disease cannot be checked on account of its rapid and virulent mode of growth. When potting the bulbs the surface of the pots should be covered with a thin layer of sand mixed with powdered charcoal. This frequently prevents mouldiness. Also the frames, &c., should be perfectly dry, well ventilated, and the pots embedded in ashes. Thereafter they may be covered about 6 to 8 inches with ashes, soil, or any kind of porous material. A bulb once attacked must be destroyed. The ashes, soil, or covering used in keeping the bulbs back should on no account be used again for bulbs of any kind, when attacked bulbs have been contained therein, because the sclerotia live in the soil for a good many years, and they will re-infect Tulips, &c. We cannot undertake to state a probable cause of the Spiræas failing. Please forward one or two of the clumps, which show the abnormal growth.—*Puzzled.* There is no disease present to account for the failure, which is therefore due to some detail in the cultivation or to want of condition in the bulbs themselves.

WALL GARDENING.

IT may be admitted at the outset that in many cases this aspect of gardening has been entered upon without a due regard for the proper positions for the walls which are to be employed as gardens, with results that have sometimes proved unsatisfactory.

I venture to submit that it ought to be laid down as an axiom that no wall garden should be formed in a position where the wall itself has not a distinct *raison d'être* apart from that of being the home of the plants which are planted in or upon it. There is no real need for erecting a wall in many places such as are at present being employed for the purpose of wall gardens, and some of these are obviously in improper positions. A wall should serve one of several purposes—a shelter, a division, a support for a bank, a boundary, or a screen. There are a few other objects for which a wall suitable for a garden is erected, but the most valuable of all for wall-gardening is one built for the purpose of a retaining support for a bank; in such a wall plants suitable for wall-gardening have a better chance of success than in any other, because they are not so much exposed to the risks of drought inseparable from those which have no great body of soil in or behind them. Many walls which have been, or are being, converted into wall-gardens would be much more satisfactory were they covered with suitable shrubs or climbers.

There are, however, many walls apart from those suitable for supporting a bank of soil, which can be usefully employed for the cultivation of plants, and of these the best are certainly those constructed for the special purpose. These should be constructed of fair-sized stones, built without mortar, and with plenty of crevices between them, while they should also be double, having a space filled with soil between the two faces of the wall, the latter being properly bonded together to prevent the wall from spreading and falling asunder, as would be the case were there no cross bands to hold the faces together. It is necessary, in building such a wall, to fill in the soil as the work proceeds, as otherwise it would settle down irregularly and leave open spaces, which would be detrimental to the welfare of the plants. It is advisable, also, where it can be done, to give the wall a slight "batter" so that the rainfall can run into the crevices, and this will also simplify the watering that will be required in continued dry weather, unless it is entirely planted with drought-resisting subjects. By giving the stones a slight tilt upwards at the front as far as is consistent with the stability of the wall the watering of the plants will be assisted in no slight degree. Such a wall should not be surmounted by the usual copestones, but should be open so as to admit of the rain finding its way down to the soil beneath. Bricks are used where stones are scarce, but the effect is not so good. Planting is best done when the wall is in process of being built, but this, of course, calls for the proper consolidation of the soil as the work proceeds. A good modification of this wall is one having one smooth face built with mortar and the other constructed with open joints for the plants. There are certain positions in which this kind of wall may be preferable, such as, for example, the screening of an ash-pit or rubbish heap, where a properly built wall is desirable for the interior, but which is required to be covered with plants on the side next the house or garden. Here, again, attention must be paid to the proper bonding of the two sides.

The retaining wall for a bank is a much simpler matter, and presents little difficulty. In all cases, however, there should be a "batter" and the slight tilt of the stones already mentioned. The degree of batter depends greatly upon the slope desired, and a little is all that is called for in this case, although when it is carried up at a fair angle it strengthens the wall immensely. I have found it desirable to place some soil between the joints of the stones as the work proceeds, making this as firm as possible to prevent any more subsidence than can be helped. It is scarcely necessary to add that the foundation stones must be "well and truly laid," and that they should be of sufficient size to prevent the wall from sinking in a soft soil, being carried down as far as necessary to a fairly firm foundation.

The task of converting an existing wall into a wall-garden is not so easy, and several methods have been adopted. An old wall, built with large joints and with loose and crumbling mortar, can be covered with plants by scraping out a sufficient quantity of the lime, and either planting young subjects or sowing seeds in good soil thrust firmly into the holes. I have found a compost of stiffish loam and cow dung answer well, especially if placed in the holes when it was in a damp state. Indeed, in some cases it is necessary to mix up clay and cow dung into a stiff, mortar-like paste with water and thrust it into small openings with a piece of wood, afterwards, when it had become a little drier, sowing a few seeds in a hole and covering again with a little soil. If a coping exists on the wall it can be utilised, if flat, by placing narrow stones or bricks on either side, so as to leave a space between the stones in the width of the cope; the vacancy is then filled up with good, rather stiff, soil, and the plants put in position.

Still another method is followed with success, and it is one which is very suitable for many walls where such a covering as that afforded by Pinks and other rather trailing plants is desired. This is by fixing pockets, formed of stones, on the face of the walls. This is effected by driving spike nails into the wall, but of sufficient length to allow of about 5 or 6 inches projecting.

On these are placed flat stones, fixed with cement to the spikes and the wall, and this has an edging of stones or cement arranged round it, and the space filled with good compost, such as that indicated for other subjects. If these pockets can be made about 6 inches deep and the wall-garden watered in dry weather, many plants will thrive admirably, and will soon leave few bare spaces between the pockets if these are placed closely enough. One of the best examples the writer has seen of this style of wall-gardening was an excellent one on a low wall beside the house of Mr. F. Bedford, the gardener at Straffan, Co. Kildare, Ireland.

As a rule, except in the case of a wall against a bank, it is desirable to select plants which can withstand a little drought at times. For the top of a wall-garden of the ordinary type of building there is nothing so good as the Flag Iris, and this is exquisite when in bloom, with the sun shining, maybe, through the translucent petals of the flowers. Carnations and Pinks are also good, and one of the features of his garden which most delighted the late Mr. F. W. Burbidge, of Trinity College Gardens, Dublin, was the original wild Carnation growing on the top of the walls. Mulleins also look well, and there are in such places admirable positions for Helianthemum, Cistus, and a number of plants which dislike too much wet at their roots and like a full exposure to the sun. For the other parts of the wall-garden the choice is embarrassingly great. Pinks, either the species of Dianthus, or the garden forms of Dianthus plumarius, are excellent, and nowhere do they look better than hanging over a wall. Such Androsaces as A. lanuginosa are exquisite on a low wall; and there are such beautiful Campanulas as C. isophylla, for warm gardens, or C. portenschlagiana, and C. garganica, with its variety hirsuta, besides a number of others, for the colder districts where C. isophylla cannot withstand the winters. In a wall-garden, however, it will be found that many plants which die out in the open garden will live and thrive. The lovely Gerbera

Jamesonii is known to the writer as thriving in a garden on a wall against a bank where it would be impossible to retain it on the level; Erinus alpinus will also establish itself on a wall where it would die in the open if on the flat, and I know one wall in particular which has thousands of plants on its surface and presenting a most delightful appearance in the time of bloom. In southern England and Ireland the Mesembryanthemums are glorious on a wall.

These notes must, however, be more suggestive than exhaustive; there are so many beautiful plants for a wall-garden that a lengthened catalogue would be needed for detail. I may, however, suggest Tunica saxifraga, Silene alpestis and S. Schafta, the silvery encrusted Saxifrages of the type of Aizoon and others, S. lantoscana, for example, being exquisite with its plumes of bloom bending gracefully from the wall. Lychnis Lagascæ will also thrive on a wall when it would die out in the ordinary rock-garden. There are also many Sempervivums and Sedums which are ideal plants for the dry and sunny wall; and flowers of quite opposite requirements, such as the Ramondias, or the shade-loving Ferns, can be accommodated on the shady sides of the walls or stone-supported banks. Some of the Lithospermums are excellent wall plants, and with sufficient soil the Gypsophilas will also succeed; Erysimum, Digitalis, and many more will give their full quota to the effect of the wall-garden; while some of the newer Wallflowers, besides the old forms of Cheiranthus Cheiri, will look well, and will thrive longer than in the other parts of the garden.

There is, indeed, practically no limit to the variety of flowering or ornamental plants which offer themselves to us for the wall-garden, when this is placed aright, properly constructed, well planted, and carefully tended; and they will assist in making our gardens more beautiful and more interesting. *S. Arnott.*

NEW OR NOTEWORTHY PLANTS.

DIACRO-CATTLEYA × COLMANIÆ

(DIACRIUM BICORNUTUM × CATTLEYA INTERMEDIA NIVEA).

THIS very interesting bigeneric hybrid (fig. 45) was exhibited by Sir Jeremiah Colman, Bart. (gr. Mr. W. P. Bound) at the meeting of the Royal Horticultural Society on February 11, when an Award of Merit was conferred upon it by the Orchid Committee.

In its habit of growth Diacro-Cattleya × Colmaniæ resembles a slender plant of Diacrium (Epidendrum) bicornutum, its fusiform pseudo-bulbs being furnished with thick, dark green leaves, and its inflorescence, 12 inches or so in height, being erect, and produced in the same manner as in Diacrium bicornutum. In Diacrium the pseudo-bulbs are hollow, but the stem of the new hybrid has the appearance of being solid, although this has not yet been definitely decided. Reference to our illustration shows that the influence of the white form of Cattleya intermedia has predominated in the size, texture, and form of the flowers, and it is interesting to note the effect of the Diacrium parentage in the retention of the peculiar form, and distinctly trilobed character of the labellum. The pure white of the sepals and petals of Diacrium bicornutum appears in the new hybrid, but the purple spotting on the lip of that species is entirely obliterated. The result is not only an interesting plant scientifically, but a very worthy new garden subject. Other crosses with Diacrium bicornutum have been raised by Mr. Bound at Gatton Park, and notably one between it and Epidendrum radicans, and in which the pseudo-bulbs are slender, like E. radicans, and furnished with aerial roots, the flowers being red.

VEGETABLES.

FORCING CAULIFLOWERS IN SPRING.

THE excellent Cauliflowers grown under glass seen at the Temple Show and earlier in the year, are examples of vegetables that are scarce and of much value at that season.

As the Cauliflower can be cultivated at a small cost in regard to space and labour, it should be more commonly grown. Gardeners who rely upon plants raised in the early autumn may experience serious losses by frost; and in order to make these good they should sow seeds of a variety that forces well and is of rapid growth. The seeds should be sown from the end of January and onwards. In some private gardens a warm-house is not always available, but a cold frame is usually to be found, or hand-glasses or "cloches," under which the seeds may be sown at an early date, and the resulting plants will provide heads some weeks in advance of those from the first sowing made in the open on a south border. As regards the varieties and the method of cultivation, much will depend upon the number required and the means available for forcing them. It is surprising how well certain sorts of Cauliflower can be grown in quite small pots from seed sown at this season. I have been enabled to cut nice serviceable heads three months after sowing the seed, grown in 6-inch pots, placed in cold frames. They also do well if planted out in rich soil in frames when just large enough to be handled; but in this case they require more care in affording air, being liable to attacks of mildew, which may likewise occur on plants in pots. Dusting with flowers of sulphur occasionally will sometimes destroy this pest.

I have alluded to pot and frame culture, but there is another system doubtless of more importance. For if the seed is grown under glass and the seedlings be afforded timely shelter for a few weeks, they may be planted out-of-doors, and give good returns some weeks before the plants grown entirely in the open come into use. I would advise that sowings be made in pans or boxes, but it is not well to crowd the plants, and the young plants must be pricked out in others to prevent spindling.

Cauliflower seeds germinate, and the plants grow, very quickly; the seedlings must at once be put into a light house near the roof glass or damping off will set in. For many years I used to raise Cauliflowers in pans placed over the hot-water pipes in a forcing house, and afterwards transfer them to cold frames; indeed, various shifts had to be made at times in order to make sure of a crop. The most critical time is at the start, since too much warmth weakens the plants, as also does thick sowing.

In a few weeks the plants that are pricked off into boxes will be large enough to plant out on a south or other warm sheltered border, or at the foot of a south wall. The soil should be well enriched. Even in such positions it is prudent to afford protection from cold winds, and it is advisable to draw rather deep drills in which to plant. At this part of the season, hand-glasses are valuable for a time. The small forcing varieties of Cauliflowers do not require much space, and about 15 to 18 inches between the rows will suffice; with this close planting protection is an easy matter. What must be avoided is the crowding of the plants.

Of varieties there are three or four good forcing ones, which are noted for their compact growth and earliness. Veitch's Extra Early Forcing is one of the best, and seed sown in February under glass and planted out late in March will be ready in May. It is a fine frame or pot variety, and the heads are close and white. The plant is unusually dwarf in growth, excellent for the earliest supplies, and of just the right size for table. Another variety is Sutton's First Crop, having small white heads of a delicious flavour; it is a rapid grower as a forcer or pot variety, and one of the earliest, not unlike the Early Snowball, but it has a closer curled head and is more compact in growth. Last year I had a new early Cauliflower of excellent quality, and quite as early as any of those named above; this was Carter's Forerunner. It is a very fine introduction, and one that will be much liked for the first crop in the open. It is remarkably vigorous, and has a larger head than the varieties already named; this will make it most valuable in large gardens. *G. Wythes.*

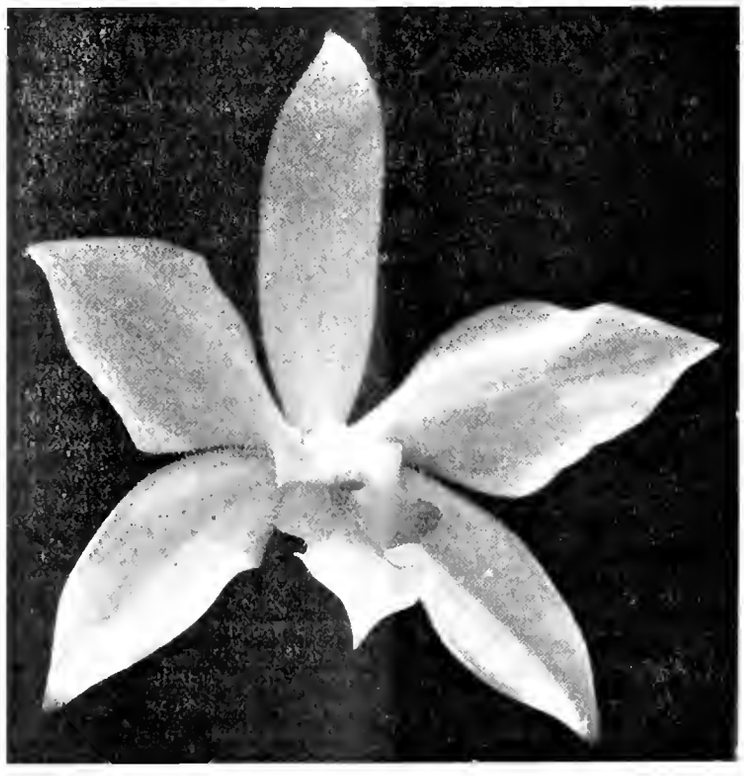

FIG. 45.—DIACRO-CATTLEYA × COLMANIÆ: FLOWERS WHITE.

RARE INDIAN LILIES.

FOR more than 30 years I have been especially interested in the different members of the genus Lilium, and in the course of that long period many changes connected therewith have come under my notice. Some species that were once popular are now comparatively rare, while others unknown, or nearly so, a quarter of a century ago, are now grown in considerable numbers.

Just now four species, natives of the temperate regions of India, viz., Lilium neilgherrense, L. nepalense, L. polyphyllum, and L. Lowii, are very rarely met with, though at one time they were by no means particularly scarce. Lilium neilgherrense, a native of the Neilgherry Hills, in India, bears, at least in some examples, the most massive flowers of all the Trumpet Lilies. In colour they vary from almost white to deep primrose, and some have the tube more attenuated than others. This extreme form represents the Lilium tubiflorum of Wight, which is now regarded as synonymous with L. neilgherrense, for intermediate shaped flowers may often be seen. Somewhere about 30 years ago, a splendid coloured plate of Lilies was presented with the *Gardeners' Chronicle*, the said plate being under my observation as I am writing. A magnificent and life-like flower of the Neilgherry Lily occupies the centre of the group, and stands out markedly from all its associates. At the time the plate was published, L. neilgherrense was very little known, but soon afterwards the late Mr. William Bull, of Chelsea, commenced importing it yearly in considerable numbers, so that throughout the greater part of the 80's it was no uncommon circumstance to find numerous flowering examples during the autumn months, for this is its usual season of blooming. Since about the year 1890 this Lily has been gradually becoming scarcer, and now in common with the three others above named, is omitted from most catalogues.

Though such a remarkably handsome Lily, and though imported bulbs never fail to flower, L. neilgherrense has never proved amenable to cultivation in this country. I tried many experiments in its culture, but all I could ensure was a crop of bloom the first season, comparatively few the next year, and perhaps two or three isolated flowers after that time. It is essentially a greenhouse species, and, as a rule, is happier when planted out in a prepared bed than in pots, since the flower stem will often, on leaving the bulb, proceed in a horizontal direction underground for some distance before making its appearance. On the other hand, the stem is sometimes pushed up directly from the bulb in the usual orthodox manner. Before the practice of retarding Lily bulbs became general, L. neilgherrense was greatly valued as the only Lily that could be had in bloom at the time of the Chrysanthemum shows, and even now, though others take its place, our gardens are the poorer for its practical disappearance.

Lilium nepalense.—It is perhaps doubtful whether any other Lily has attracted as much attention on its first appearance as did this species when shown by Messrs. Low on September 11, 1888, on which occasion a First-Class Certificate was awarded it by the Royal Horticultural Society. True, it is said to have been introduced some years before, and to have flowered in this country, but prior to 1888 many conflicting opinions prevailed as to what L. nepalense really was like; therefore when it proved to be such a distinct and beautiful plant everyone was delighted. The flowers, which are of a short, funnel shape, have the segments reflexed almost to the same extent as some members of the Martagon group. The centre of the flower—that is, the basal half of the segments—is of a rich chocolate-purple colour, while the reflexed portion is a kind of greenish-yellow. There is, however, a good deal of individual variation to be found in the colour of the blossoms, some having the purplish tint much more highly developed than others. Lilium nepalense reaches to a height of 4 to 6 feet, and flowers during the autumn months.

Lilium polyphyllum.—This Himalayan Lily is an exceedingly pretty member of the Turk's Cap section, with narrow, elongated bulbs suggesting in shape those of the Siberian L. tenuifolium. The bulbs of L. polyphyllum are, however, the larger of the two, and from them are pushed up stems that reach to a height of a couple of feet or thereabouts. The flowers, which have the marked reflex characteristic of the Martagon group, are in colour a kind of greenish-yellow marked with purple. Generally speaking, this Lily must be regarded as a greenhouse species, but the late Mr. G. F. Wilson used to succeed wonderfully with it out-of-doors at Oakwood. Now it seems to have almost dropped out of cultivation.

Lilium Lowii (also known as L. Bakerianum).—A native of Upper Burmah, and introduced in 1893, this Lily seems now to get scarcer year by year. It is of slender growth, with very narrow leaves, while the bell-shaped flowers are white, freely spotted in the interior with purple, though in this respect there is a considerable amount of variety.

Although the above Indian Lilies are all difficult to establish, and on this account are exceedingly rare, one species, also a native of Upper Burmah, viz., L. sulphureum, has proved hardy in the southern portion of this country, and become established in places. It is somewhat strange that this should be the case, for it is, I believe, often met in a state of nature associated with L. nepalense, which last is so difficult to grow. A curious feature of L. sulphureum—which, by the way, was first known as L. Wallichianum superbum—is the presence of a quantity of bulbils in the axils of the leaves, which causes it to stand out unique among the Enlirion or tube-flowered group of Lilies. Even where it is not hardy, L. sulphureum is a very handsome Lily for the greenhouse in late summer or early autumn. Good bulbs can now be obtained at five shillings each, certainly not an extravagant outlay for such a fine Lily.

Though it cannot be termed rare, the noble Himalayan Lilium giganteum merits at least a passing notice, for in its striking heart-shaped leaves, its towering flower shaft, and long, tubular blossoms, it is totally distinct from any other member of the genus. *W.*

PLANT NOTES.

CRAMBE CORDIFOLIA.

THIS Circassian species, belonging to the Cruciferæ, is not a common plant in gardens. The plant possesses large leaves and attains a height of 7 feet, and is quite hardy, growing in any good garden soil. It is readily increased by seed or division, and seedlings usually blossom the third year.

ITEA VIRGINICA.

THIS is an American shrub of much merit, growing about 8 feet high. The flowers are white, and appear in June in drooping racemes from 3 to 5 inches in length. Its other attraction is the deep red of the foliage in the autumn, making it one of the best at that season. The plant requires a moist soil, and is, therefore, a very suitable one for planting on the margins of lakes and streams, either singly or in groups, the latter being the best for effect. *F. M.*

IXORA MACROTHYRSA (SYN. DUFFII).

I HAVE seen this stove-flowering plant, grown as single stems about 4 feet high, with trusses of blooms fully 16 inches across, which have preserved their freshness and beauty for over five weeks. The flowers, which are borne in immense terminal corymbs, are of a rich deep vermilion colour, shaded with crimson, and are set off to great advantage by the deep green leaves which often attain a length of 9 and 10 inches. This Ixora being a native of the South Sea Islands requires abundant heat and moisture, and should be given a light position, free from draughts or checks of any kind. It is best grown as a single stem, and flowered in about a 7-inch pot. Propagation is effected by cuttings, taken preferably in the early summer or early autumn, in which case the plants would be at their best about the following October. When taking cuttings it is advisable to select short-jointed shoots, and when detached, the cuttings should be carefully split into (but not through) the node, which will greatly aid them in striking. The cuttings should be inserted singly in small pots, in sandy peat, and plunged in fibre with about 80° bottom heat. When well rooted, which often takes five or six weeks, they should be potted on into a compost of fibrous peat, with a little good loam and plenty of sand. Good drainage is essential, as the roots soon suffer if the soil becomes sour. While the plants are growing they must be well supplied with water and freely syringed to keep down mealy bug and red spider. The young plants require shading from the sun when it is very bright, though plenty of light and heat are at all times essential. Great care should be taken as regards ventilation, if any is necessary, when the plants are coming into bloom, as a cool, draughty, or foggy atmosphere will cause the flowers to drop in a most disastrous manner. *W. H. Middleton.*

NOTICES OF BOOKS.

"MISSOURI BOTANIC GARDEN, 18TH ANNUAL REPORT, ST. LOUIS, 1907."

THIS well-known American garden issues, as is well known, rather bulky annual reports. The current volume contains matter of considerable interest, apart from the details of the routine work of the institution. A lengthy illustrated article deals with the literature of Furcræa, with a synopsis of the known species. The author, Mr. J. R. Drummond, has dealt with many of the Kew types. An abnormal Odontoglossum Cervantesii, and a virescent form of Oxalis stricta are described by Henri Ilus. The latter plant seems generally to come true from seeds, and has been distinguished as var. viridiflora. T. W. Blankenship contributes the third part of the Plantæ Lindheimerianæ, containing an interesting biography of Lindheimer himself. The volume closes with articles by Dr. William Trelease on additions to the genus Yucca, and on Agave macroacantha and allied Agaves, both of which are illustrated.

"FERTILISERS AND FEEDING STUFFS."

THIS excellent little work has deservedly reached a fifth edition. It is written primarily for farmers who have had no scientific training, though references to standard works are given for the benefit of those who can profitably use them. Dr. Dyer is a leading authority on the subject with which he deals, and he understands how to convey a very large amount of invaluable information in the simplest language. The book ought to be widely known and read.

[1] By Bernard Dyer, D.Sc., with notes on the Fertilisers and Feeding Stuffs Act, 1906, by A. J. David, F.I.C. 5th edition revised. 1908: Crosby, Lockwood & Son; price 1s.

USES OF THE MOTOR IN HORTICULTURE.

(Continued from page 100.)

The next vehicle to consider is that designed to carry from 2 to 2½ tons.

A chassis of this description, without body, may be purchased for £500.

This vehicle will probably answer the purpose of most people interested in horticultural enterprise better than the 4-ton vehicle—that is, it will appeal to the majority.

Before going further with this article, it may be as well to point out that the main object is to show, as clearly as possible, what may be done with motor vehicles provided that they are given reasonable care and attention. The figures given for depreciation and repairs are particularly high, and considerable allowance is made for depreciation, not that at the end of five years the motor is of no further use to its owner; on the contrary, it should be just as useful and capable of doing its work as well as on the day it was purchased, and in the meantime it will have paid for itself. Depreciation really should not be put down at any fixed percentage. For instance, if this item be deducted from the running costs of the 4-ton vehicle given above, the road mileage will be 6d. instead of 8d., and the ton mileage from 2d. and 4d. to 1½d. and 3d. respectively. The prospective purchaser should compare these figures with what his present method of transport is costing him, allowing also for the probable saving which will be effected by less packing as required by rail transport, or if it is an outlying piece of land which is to be developed, then the saving in rent or purchase of land must be credited to the motor. It will also be found that the goods will be delivered in better condition than by rail every prospective purchaser is given a fair trial of the vehicle, when this will be demonstrated to him; this, too, should be taken into consideration. If all these items combined will not show a sufficient saving to pay for the vehicle within a period of four years, then the writer would advise that the purchase should not be made.

With reference to repairs, provided that the adjustments and lubrication are properly attended to by the driver, and that the vehicle is not over-loaded or over-driven, it will be found that no repairs are required until it has run between 18,000 and 20,000 miles, except to the brake blocks, which will have to be renewed periodically. Breakages, if any, due to faulty materials, will be made good by the manufacturer, i.e., if the purchase be made from a firm of repute, and the necessary guarantee obtained. There is at least one firm that makes excellent vehicles and is prepared to supply them on the hire purchase system. The extra cost amounts to 5 per cent. per annum on the first cost of the motor. In addition to this, the vehicle can be maintained in good working order at a fixed sum per annum, for a period of years. This should appeal to those who might not find it convenient to pay out such a large sum of money on delivery of the motor. The maintenance contract would also settle any doubts there might be as to the running costs.

To return to the 2-ton to 2½-ton vehicle, the annual cost of running is made up as follows:—

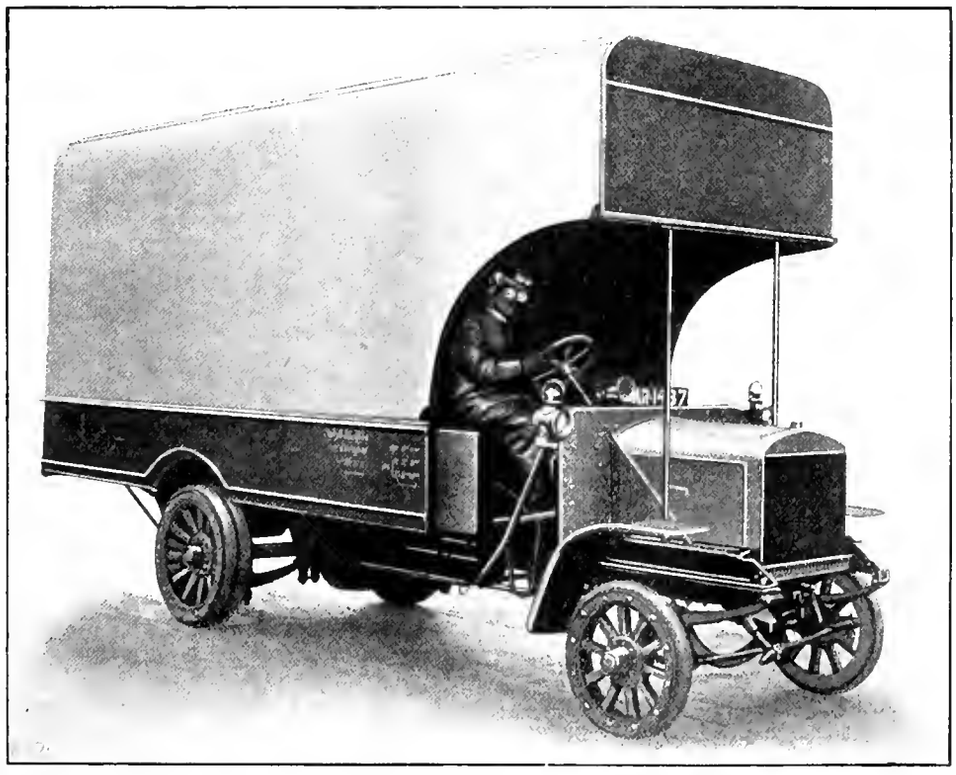

FIG. 46.—MOTOR VAN CONSTRUCTED FOR JOSEPH ROCHFORD, AND HOLDING 290 "FLATS" OF GRAPES.

TABLE No. 2.

Depreciation on £500 at 20 per cent.	£100	0	0
Petrol, 1½d. per mile for 26,000 miles	162	10	0
Tyres, 1¼d. per mile for 26,000 miles	135	8	0
Repairs, 10 per cent. on £500	50	0	0
Driver, 52 weeks at 35s.	91	0	0
Oil, waste, light	7	10	0
Sundries, insurance, &c.	25	0	0
	£571	8	0

The figures are based upon 500 miles per week, as the lighter weight permits of a higher speed.

The cost per road mile is approximately 7¼d., and per ton mile loaded one way 5½d., or loaded both ways 2 9-10d.

The 30-cwt. to 2-ton van will cost £385, and as in the difference between the 4-ton and the 2½-ton vehicles, the differences in the running costs only vary in the three items—depreciation, petrol consumption, and tyres. Compare Tables No. 1 and 2:—

Petrol, 2d. per mile.	Petrol, 1½d. per mile.
Tyres, 2d. per mile.	Tyres, 1¼d. per mile.
Depreciation on £700.	Depreciation on £500.

It is the opinion of the writer that the figure for repairs should not be put down at less than £50.

Then the running costs work out as under, and also based upon journeys amounting to 500 miles per week:—

Depreciation on £400 at 20 per cent.	£80	0	0
Petrol, 1d. per mile for 26,000 miles	108	6	6
Tyres, 1d. per mile for 26,000 miles	108	6	6
Repairs	50	0	0
Driver, 52 weeks at 35s.	91	0	0
Oil, waste, and light	7	10	0
Sundries, insurance, &c.	25	0	0
	£470	3	0

The cost per road mile is 4 3-10d., or 2⅘d. per ton mile fully loaded both ways, and 5¾d. loaded one way only.

On a similar mileage the cost of working a 20 to 25-cwt. van works out at £396, and for a light delivery van to carry from 5 to 8 cwt., £180 per annum. A tri-car suitable for a lad to drive and to carry 3 to 4 cwt. may be purchased for £80, and the upkeep will be about the same rate.

Compared to horse traction, the cost by motor shows a saving of at least 50 per cent., and in some cases much more than this; the matter depends largely on the conditions of delivery.

In the above figures it may be noticed that only £7 10s. per annum is allowed for lubricating oil, &c., this will probably be found to be not quite sufficient. It is necessary to draw special attention to this item, because although there should be no stint in the use of the oil, precaution should be taken to prevent the prodigal waste that takes place.

In all other cases the figures are rather above than below the amounts necessary.

Careful record should be kept of the petrol consumption, so that as soon as the number of miles per gallon show a falling off, the cause may be sought for and remedied. There is no surer method of checking the efficiency of the vehicle than this.

Before many months have passed, motor-carrying businesses will be established that will cater for the small growers who have not sufficient produce to fully employ a vehicle of their own. These, of course, cannot expect to get the work done so cheaply as those in a more fortunate position, but in a greater or lesser degree the benefit of motor transport will make itself felt throughout the market-gardening world. To thousands of growers the day they are rendered independent of the railway companies will be the dawn of future prosperity. *Hugh Miller, C.E., M.E.*

(To be continued.)

NURSERY NOTES.

PRIMULAS AT READING.

At the present time many of the glasshouses in the nursery of Messrs. Sutton & Sons are filled with the various kinds of Primula sinensis and its allies, in conjunction with the firm's well-known strain of the florists' Cyclamen. The display of Primulas is not of the nature of a comparative trial, but rather shows the cultivation of a series of types and varieties, some so fixed in character as to reproduce almost the whole of their progeny true from seed. The ungainly plant, big of leaf and of stem, is apparently unknown at Reading, but there are hundreds and thousands of plants that impress one irresistibly by their uniformity of habit and their large flower-trusses, which over-top the

leaves. In the "giant" or "magnifica" and other types the heads of flowers (in many shades of colour) are lifted well into view, although naturally the "pyramidalis" and "stellata" types have the most exalted inflorescences. The flower spikes of some of the "star" Primulas at Reading range from 12 inches to 20 inches in height, the plants being of quite an ordinary size and growing in pots not more than 5 inches in diameter. For some years past the varieties of the stellata group have been exceedingly popular, and so much in demand that in certain instances, despite the large number of plants grown, the firm have experienced some difficulty in securing sufficient seeds for their requirements. The plants when in flower are eminently suited for table decoration and for many other purposes, whilst they are useful for supplying cut flowers at a season when other flowers are scarce. Some of the more important varieties of this group are White Queen Star, Ruby Star, Ruby Star (double), Dark Blue Star (almost equal in colour to the famous "Czar" in the large-flowered type), Lord Roberts (a pleasing tone of salmon), and Mont Blanc. The last-named, while providing a Fern-leaf character, retains the chief characteristics of the true stellata type, with dark leafage coupled with large and pure white flowers. Mont Blanc and White Queen, the latter with opaque white flowers, represent the best of the white-flowered forms. There is, however, a move forward to varieties having very large flowers, and these are known as "Giant Star" in their several colours, White Carmine, &c. The beauty and the elegance of these stellata forms cannot well be over-estimated.

The pyramidal strain may best be described as being midway in habit between the old florists' and the stellata forms. There is also a type represented by the magnifica hybrids, with their large, handsomely fringed flowers in shades of rose-pink, crimson, &c., and with foliage decidedly ornamental in character. Perhaps the most remarkable section of all these Primulas is that known as "The Duchess," remarkable alike for its own intrinsic beauty and merit and for its almost unique progeny. The original of this group received an "Award of Merit" from the Royal Horticultural Society some six years ago, and at the present time its influence may be seen in one of the finest hybrid races among these plants. Such well-marked varieties as Crimson King, Brilliant King, Lord Roberts (salmon), The Czar (violet-blue), Brilliant Rose, &c., constitute the best selection of the self-coloured forms. Pearl, a variety of 30 years' standing, and Snowdrift, are instances of fixity of character and absolute trueness to type. Plants of these varieties seen at Reading and raised from seeds are of remarkable uniformity of habit, and afford evidence perhaps of the limit in their particular direction in plant evolution.

Of the "giant" strain it may be said to be unique, and any attempt to exalt or glorify the beauty of the flowers would be superfluous.

Many thousands of Cyclamens are also grown at Reading, and here again we meet with great size, brilliancy of colouring, and good form in the flowers that are set off by the handsome foliage. *E. H. J.*

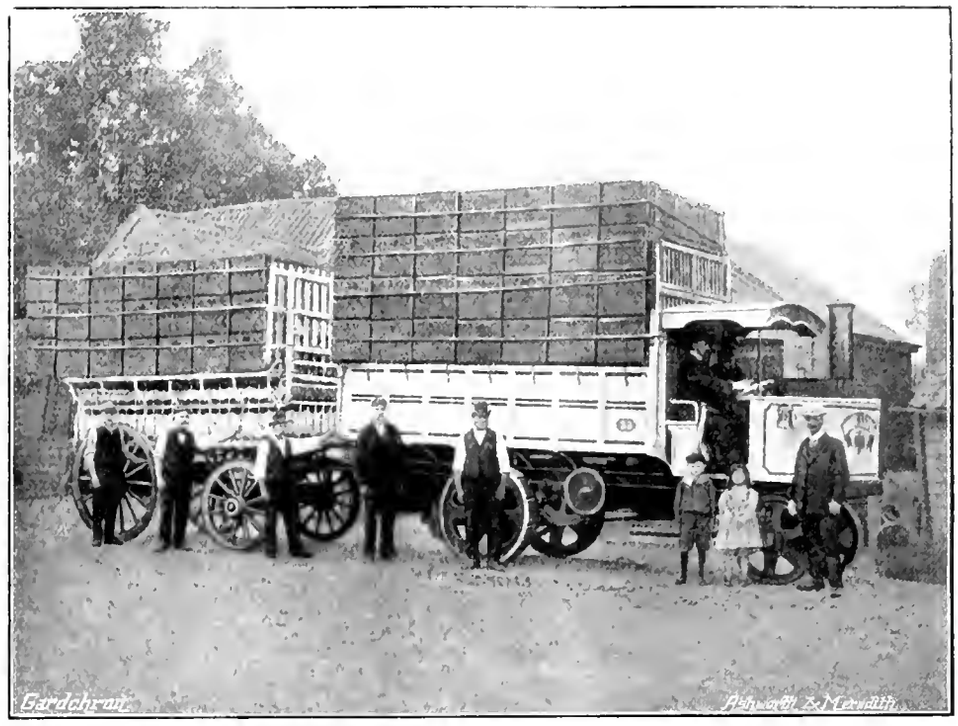

FIG. 47.—MESSRS. MANN AND SONS' STEAM TRACTOR LOADED FOR COVENT GARDEN MARKET.

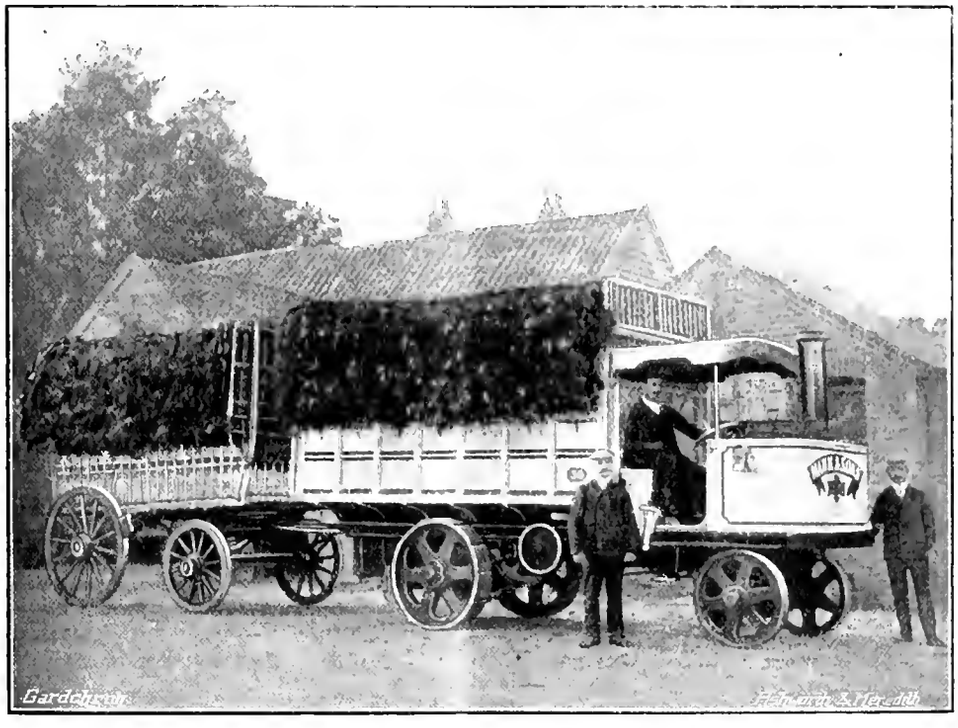

FIG. 48.—THE TRACTOR RETURNING LOADED WITH MANURE.

THE ROSARY.

ROSE MRS. JARDINE

AN American, writing in the *American Florist* for December 21 last, gives it as his opinion that this variety, raised by Messrs. Dickson & Son, Newtownards, Ireland, is "one of the most beautifully formed flowers of any Rose now in cultivation. The colour is between Bridesmaid and Killarney. It is also fragrant—a very good feature. The flowers are borne on good stout stems. The habit of growth is vigorous and strong, with buds forming on every new shoot. It is said to bloom continuously, being more prolific than Bride or Bridesmaid." I am curious to know if this eulogistic expression is borne out by growers in this country.

NEW VARIETIES OF ROSES IN THE U.S.A.

"A LEADING society lady in the U.S.A. gave utterance to the protest against being compelled to wear Bride, Bridesmaid, or American Beauty, for her frequent functions; this was only too true, and the lady in question simply gave utterance to the general complaint concerning the pre-eminent flower, the Rose. A change has taken place, and new varieties are accorded a very different position from that given a few years ago. It is well for the Rose that such is the case, else the Carnation would have continued its triumphant march to the point of disputing the leadership with the Rose. . . . So many qualities have to be present in a variety that lays claim to favour as a forcing Rose that the progress made will seem slow, but nevertheless it is within the range of possibility to gain entirely new and unique colours and forms." The foregoing is extracted from a paper read before the Chicago Florists' Club by Mr. E. G. Hill, of Richmond, Ind., on December 12 last. He further said that in his belief the forcing varieties of the Roses of the future will come largely from an admixture of Rosa rugosa with the present H.P.'s. Still, the strong old Bourbon varieties like Gloire de Rosomanes should be made to furnish their rich scarlet tones to the new varieties.

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Aerides, Vandas, &c.—Orchids now claiming attention include Vandas, Aerides, Angræcums, and Saccolabiums. The plants should be examined and be either repotted or afforded fresh material at the surface, according as each particular case demands. The larger species should be grown in pots on the stage, while the smaller kinds should be given a position near to the roof, from which they should be suspended in teakwood baskets or small pans from the rafters. All these plants when in a strong and healthy condition require plenty of pure air and sunlight. They should not be kept excessively dry at the roots at any season. With the lengthening days and increasing activity of growth the supply of moisture, both at the roots and in the atmosphere, should now be increased, and whenever the outside conditions will admit, overhead spraying should be practised. The majority of these species are best accommodated in the warmest division of the range, but very satisfactory results can be attained, and especially with Vanda and Aerides, when they are placed in the warmest end of an intermediate house.

Vanda cærulea.—Judging from the enormous quantities of this plant imported annually, it is more extensively grown than any of the other large growing members of the genus. It is a free-blooming, healthy-growing plant when properly treated. I find they thrive best in a temperature slightly higher than that generally afforded to Odontoglossums, and while these Vandas enjoy a cool treatment they are not adversely affected by solar heat, providing that abundant moisture and ventilation are afforded them. They, however, enjoy the cool night temperature, and at that time recoup their energies after the heat of the day. Thus treated, the growth of these plants is active, free, and of a harder and more vigorous nature than that produced under hot and close conditions. The plants, too, are more free in blooming, whilst the flowers produced are of a better colour and have increased substance. The pretty species V. Amesiana, V. Kimballiana, and V. Watsonii should also be grown in a cool, intermediate temperature, and being small in habit, are best suspended close to the roof ventilators. Aerides japonicum and A. vandarum should be given a similar treatment.

Repotting and compost.—Fresh rooting material should be afforded these plants annually. Equal parts of Osmunda fibre, well broken up, and clean fresh sphagnum-moss, with a liberal addition of coarse silver sand, broken crocks, and charcoal, the whole well mixed together, forms a good compost in which the fleshy roots of these plants will thrive. When potting, provide plenty of material for drainage and pot moderately firmly. Finish with a surfacing of fresh moss, trimmed neatly. Healthy plants that are furnished with leaves down to the surface of the compost need not be repotted, but they should have all the old rooting materials carefully picked from amongst their roots, and the drainage made perfect, after which some of the new compost should be worked in to within an inch of the rim of the pot. Specimens that have become "leggy" should have the leafless lower portions of their stems removed so that when the plants are repotted the lower leaves will be on a level with the rim of the receptacle. All aerial roots produced during the growing season should be induced to enter the rooting materials.

PLANTS UNDER GLASS.

By THOMAS LEGG, Gardener to A. SPELING, Esq., Kier, Perthshire, N.B.

Stove plants.—These plants should now be examined to see whether they need repotting, and any that do not require it should have the drainage placed in perfect order—a very important point. Care should be taken to place one large hollow piece of crock over the hole, with its hollow side downwards, with smaller pieces covering it, and over these should follow a sprinkling of finer crocks which have been passed through a ½-inch meshed sieve. It is not the quantity of crocks that makes good drainage, but the way they are placed, so as to take up as little space as possible. When repotting put in a small quantity of soil at a time, and press evenly down round the side of the plant with a flat smooth rammer to the required firm condition. The finer the roots of a plant, the more firmly it should be potted and *vice versâ*; this is a good rule to follow in repotting most plants.

Ferns.—Hothouse Ferns will now require repotting and examining. The soil most suitable for nearly all species of Ferns is a light, sandy, fibrous loam, peat, leaf-soil, sand, and finely broken lime rubble, together with some broken soft bricks. In repotting, the new soil should be very firmly rammed with the potting stick and be put into the pot in small quantities only, and a few bits of broken bricks put near the surface of the soil will also be beneficial to the plants. Although Ferns grow best in a firm soil, it should be of a very porous nature, so that the water applied may pass readily away. Shading should now be placed on the fernery, or the bursts of bright sunshine will scorch the new fronds. Blinds should be placed on all hothouses that require shading, and strict attention should be given not to allow the blinds to remain down whenever the sunshine is gone. Neglect to this point will cause plants to become drawn and weakly.

Amaryllis.—Bulbs which are starting into growth should now be removed to a light position in a warmer house, very little water being afforded at this stage, but they should be syringed twice a day until the flower spikes appear, when a small quantity of weak manure water should be applied regularly, increasing its strength later on. As soon as the flowers open, remove the plants to a cooler house. Amaryllids flower more freely if they are allowed to fill their pots with roots and are fed liberally with liquid manure. After flowering place them in a place suitable for ripening the bulbs and leaves, so as to secure good flowering the following year, water being gradually withheld until the leaves are decayed, or in the case of such as are evergreen, till the soil is dry.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Fig trees.—Where the trees are grown out-of-doors the materials used during the winter against injury by frost may now be gradually removed in the milder parts of the country, and the necessary pruning operations carried out. These will consist in removing as much of the older wood as can be spared and any shoots that have been damaged by frost, leaving a sufficient number of young shoots without shortening them, as it is at the extremities of these that the fruits are produced. Pruning should be very carefully done on trees that are growing in unconfined borders, or nothing but gross shoots will be produced by such trees, and these will never ripen nor bear fruit. It is better in the case of Figs to have the roots in borders restricted as to width and length, which may be done by digging a trench about 4 feet from the main stem, more or less according to the size of the tree, severing all the strong roots, and filling it with brickbats or similar rough materials. By this means and by careful disbudding, well-ripened and short-jointed shoots will be ensured and but little pruning with the knife required. Trees that are growing in restricted borders should be top-dressed with loam, wood ashes, and mortar rubble, reduced to a fine state, together with a sprinkling of bone-meal, mixing all well together before use. Liberal applications of liquid manure to these trees, as soon as the fruits attain to the size of Walnuts, will be beneficial. In planting the Fig afford ample drainage materials. Plant only against south or west walls in gardens north of the Humber river. Make the border thoroughly firm, so that the shoots will be short-jointed, and do not make use of a too rich mixture of soils. The chief ingredients should be good pasture loam one year in stack, mortar rubble, and wood ashes. It is better to apply manurial top-dressings afterwards than to make a border excessively rich.

Grafting.—If fruit tree grafting is contemplated, the present is the most suitable time for heading down the stocks before the sap begins to rise. In cutting off the crowns of large trees the limbs or branches should be left sufficiently long to allow of being shortened by about 1 foot at grafting time. If the shoots from which the scions will be cut have not as yet been taken, these should now be secured and laid-in in thin rows or very small bundles in the soil beneath a wall with a north aspect or under shady trees. Examine trees grafted last year, and if the grafts have made good growth cut back any of the stronger shoots if more branches are wanted to form the framework of the tree, and remove all weak and useless shoots unless the flow of the sap is likely to be excessive. In the case of trees that were grafted two years ago, and on which the scions have taken successfully and growth is likely to become too dense, those worst placed should be removed entirely so as to let in the sunlight, otherwise much mischief will result next year.

Labelling trees.—Take advantage of bad weather when outside work is impossible, to put lasting labels to all the newly-planted or other trees, a list of the names having been prepared some time ago. Fruits in the Apple and Pear rooms should be frequently examined, and every fruit that shows signs of decay removed, the sound fruits being handled as little as possible. Pears are mostly over for the season, but late varieties of Apples will remain good for some time longer.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Early Melons.—For Melon plants raised in the manner previously advised, make a firm ridge of loam inclined to be clayey, mixed with a small quantity of fresh soot and crushed mortar rubble or leaf-soil, on a firm hot-bed. Once the ridge, or hillock, of soil is warmed through, the plants, after being moistened at the roots, should be firmly planted upon it at 2 feet apart, and the stems trained on the cordon principle to a trellis fixed near to the roof glass; side growths, as they form at the base of the stems, should be rubbed off, and the principal leaves carefully preserved. With a view of securing very early fruits, some of the plants should be stopped when they reach to about 18 inches up the trellis. The superfluous male blossoms should be removed at short intervals, thus promoting the growth of fruitful lateral shoots; these should be secured to the trellis as they extend, and be stopped at one leaf beyond the first fruitful blossom. The rest of the plants may be allowed to extend their shoots and strengthen them before being stopped. These plants will subsequently yield fruits in succession to the former. Attention must be paid to the ordinary routine of Melon culture during the flowering period, and a buoyant, fairly dry atmosphere maintained. Plants that are to be fruited in pots should receive the same kind of treatment, and seeds sown as may be required for successional crops. In the above manner are Melon plants managed at the Hendre Gardens.

Early Peaches and Nectarines.—As soon as the blossoms fade, the morning syringing of the trees should recommence, and on fine days it should be done sufficiently early in the afternoon likewise, so that the trees may get dry before nightfall. Regulate the temperature of the house as soon as the fruits begin to swell freely, so that at night it may range from 55° to 60°, and about 5° higher than these figures during the day. Admit a little air early in the morning, increasing the volume gradually if the day is sunny, and gradually reducing it as sun heat declines, finally closing the ventilators so as to keep the house for a short time at 65° to 70°. Disbudding should begin at an early stage of growth, and be followed up gradually so as not to cause any sensible check to the flow of the sap. In the formation and maintenance of a perfect tree, disbudding plays an important part, and much foresight and discrimination are called for. A beginning may be made in thinning the fruits on trees that are carrying too many as soon as they have reached the size of Hazel-nuts. The final thinning should not be carried out until the fruits begin to form a hard stone. Let the borders be tested for moisture at intervals of two or three weeks, and afford water copiously when

it is seen to be required. Manure water should be supplied when extra assistance is needed, using mild applications of artificial manure or diluted liquid manure from the stable or cattle shed.

Early-fruiting permanent Vines.—A sufficient number of the best lateral shoots of the early vines having been retained to clothe the rods—these being stopped at the second or third leaf beyond the selected bunches of fruit a few days before the blossoms expand—they should be carefully secured to the wires, and the sub-laterals pinched back to a single leaf. Maintain a tolerably dry and freely circulating atmosphere, assist the fertilisation of the blossoms in the usual manner, and do not delay to remove the over numerous bunches or to thin the berries of those bunches that are to remain, which should not be so numerous as to over-tax the strength of the vines. Supply nutriment to the roots according to the strength of the vines, remembering that it exerts the greatest effect when applied with discretion in the earlier stages of the development of the fruit, the stored-up sap having then become exhausted and root growth more active.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

THE exceptional weather experienced in this locality during the past month (scarcely any rain having fallen during that period) has kept the land in good working condition for getting in early seeds and accomplishing various other seasonable work.

Autumn-sown Onions.—This is one of the earliest crops to need attention, and far better results are obtained by transplanting the plants to a well-enriched, deeply-trenched piece of ground than by allowing them to remain where the seed was sown. Take the earliest opportunity of carrying out this transplantation. Apply to the surface of the ground a thorough dressing of soot and wood ashes, and afterwards rake it down finely, leaving it as level as possible. Plant the Onions in rows drawn at distances of 1 foot to 15 inches apart, putting each plant 10 to 12 inches distant from each other. Make the soil very firm about the roots, and if dry give a thorough watering. Any spare plants should be pricked in thickly together on any odd piece of ground for early use. White Emperor and White Leviathan are distinct varieties and are among the best for furnishing early supplies, but as both are bad keepers they should not be planted too freely, the Rocca varieties being better for later use.

Shallots.—These should be planted immediately if this work has not already been done; they are perfectly hardy, and the earlier the growth is made in the year the better for the plants. Providing the ground is well enriched each season, Shallots may be allowed to occupy the same site for a number of years together. Soot and farmyard manure should be incorporated freely with the staple.

French Beans.—Little difficulty will now be found in getting a plentiful supply of this favourite vegetable. Plants which are fruiting should be given copious supplies of liquid manure and occasional applications of "Clay's Fertiliser." Maintain a moist atmosphere and thoroughly drench the foliage twice daily with tepid water, and from now onwards do not employ strong fire-heat; an atmospheric temperature ranging from 55° to 65° will be ample. To maintain a continuous supply of this vegetable, sow seeds at intervals of ten days or a fortnight. At this season I prefer to sow Canadian Wonder rather than any other variety. Its vigorous constitution ensures success under forcing conditions.

Turnips.—Seeds may be sown in fine soil on quite mild hot-beds in portable frames near the glass. They resent hard forcing, but excellent young roots may be obtained quite early in May if treated as I describe. Both Early Red and White Milan are excellent varieties; so also is Carter's Forcing, a long-rooted variety possessing much merit and one we have grown for some years past. Matured roots of Turnips in the open ground should be pulled and stored in the coolest place possible (one under the shade of a north wall for choice), or these will soon be growing apace and be of little value if left in the ground. Avoid placing too great a quantity together, or they will develop heat and become useless.

Mushrooms.—Beds which were made up in the open during last autumn should now be yielding good crops. The old material which has been used for covering should be entirely removed and replenished with new. Those beds in the Mushroom house which are in bearing should be damped twice daily, and those which have been in bearing some time may be given a good soaking of farmyard liquid in a warm state. Strictly avoid employing fire-heat after this date unless the weather be exceptionally cold. More Mushrooms are spoiled by excess of fire-heat than from any other cause. Make up other beds at regular intervals.

PUBLIC PARKS AND GARDENS.

By JAMES WHITTON, Superintendent of the Parks and Open Spaces in the City of Glasgow.

Larger areas.—As regards still larger areas, intended for the purpose of playing grounds, say, from 1 to 4 acres, there is room for greater variety, and opportunity may be presented for making the place a recreation ground in a wider sense. It must, however, always be borne in mind that the main object is the provision of a playing-space for children not over school age—that is, 14 years. Nowadays, to kick something seems to be the main desire of the majority of town boys, and to provide a space whereon they can exhaust this exuberant energy in the playing of football is to meet one of their chief requirements. Therefore, in planning these grounds, a pretty full share of the available space should be allotted for that game. As cricket is not so popular with boys in the North, we are not so often called upon to cater for that game; still, as a grass sward is more desirable than one devoid of a green blade, in some towns provision is now being made for the youthful cricketer. Space for games suitable for girls has also to be considered, for in such cases the requirements are in favour of conditions more pleasant to the eye. In most towns of any size, examples showing good and bad features are to be seen. A careful study of these will show what to avoid, and this is perhaps of more importance than the imitation of some merely striking feature.

An example.—Though it is not quite up to the highest ideal of what might be accomplished, I may describe one example which has met the requirements of a district more fully than was expected. The site formed part of an exhausted brickfield, is about 4 acres in extent, and was set off as a building plot. On its acquisition, certain restrictions were made as to its use, while the place had to be enclosed by an ornamental iron railing. As the term ornamental is one of those delightfully vague expressions, no difficulty was encountered when a simple but sensible vertical railing of the so-called unclimbable type was erected. Inside the boundary railing is a border of trees and shrubs which act like a frame to a picture, while a strip of grass with a series of simple flower-beds on a circular plot of grass at each corner completes the main border. Then follows a path 8 feet in width, which is bordered by a breadth of grass and a line of trees. The central area is thus nearly a parallelogram with the corners rounded off, and it is bisected by an ordinary field fence. One half is set down with ashes, and its area is surrounded by a fence covered with wire netting, so that the boys when playing football are kept within the area. Goal-posts are prohibited, but the smaller boy has other expedients to mark the goals. This arrangement has proved highly successful. In the case of the other half of the central area, which is laid down with grass, there is a double set of swings and giant strides erected in a square, which is floored with tar macadam. The caretaker's and the general shelter, with conveniences, is built as one block exactly in the centre of the ground, the shelter for boys facing the ashed area, and that for girls the grassy one. Here we have a type which has met with much approval from park and sanitary authorities when investigating municipal establishments. The place in question serves its primary purpose as a playground for children; it also serves as a visiting ground for invalids, and mothers with infants, so that the path round it is well supplied with seats. A source of interest is created by the trees and shrubs and the few simple flowers put in the beds in summer and spring. It adds considerably to the amenities of the locality, and the dwellings overlooking the playground command a higher rental than others in the vicinity.

In the laying out of such places, it is assumed that all the work will be carried out intelligently and on the most approved methods. The only point calling for special remark is the necessity of providing thorough drainage to the spaces allotted for games. In our wet locality, with a retentive clay soil, we have in some places put in 4-inch field drain tiles in lines 6 feet apart, and covered these with rough cinders and ashes; even this is not more than enough to serve the purpose.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Propagating Dahlias from cuttings.—The old tubers should now be placed in a temperature of 55° in a position near to the glass, and should be lightly covered with soil. An occasional syringing with clear water will induce the formation of sturdy shoots suitable for cuttings. These should be detached with a sharp knife, and be inserted singly in small pots filled with sandy soil. They will soon form roots, after which they should be gradually hardened. If the ground in which Dahlias are intended to be grown has not been already prepared, it should be well dug and freely manured, throwing the soil up roughly with the spade during the process.

Seeds of single Dahlias may now be sown, but their propagation from cuttings is to be preferred.

Abutilons raised from cuttings, inserted about September and that are now well established in 6-inch pots, will furnish fine specimens for planting out about June.

Fuchsias intended for summer-bedding purposes may be trained either as dwarf, bush, or standard plants. They should now be removed from their winter quarters into a warmer structure, and as soon as they break into leaf they should be cut back, have the old soil shaken from their roots, and be re-potted in a mixture of rich sandy loam and leaf-soil.

Seeds.—I am now sowing seeds of certain plants that have produced fine effects in beds and borders from June to November. The chief points to observe are to make the soil in pots, pans, or boxes moderately firm, to sow the seeds thinly, and from the start strive to secure the sturdiest possible growth. A moderately warm greenhouse is the best structure in which to place these seeds, and old soil obtained from the potting bench, sifted well, the most suitable soil. The dwarf, or so-called carpet, varieties should have their shoots pinched early in order to induce a dwarf, spreading habit of growth. Seeds of Antherieum, tall, medium, and dwarf; Browallia elata, Dianthus Heddewigii, and D. sinensis, Petunias, Lobelias, Pyrethrums, Verbenas, Nicotiana Sanderæ and N. sylvestris, and Marguerite Carnations may be sown thinly, each in quantity sufficient to make a feature when seen at a distance.

Carnations.—When these plants are employed in beds or borders in the grounds, the soil should be well prepared now, or, if this was done earlier, it should receive a dressing of wood-ashes, lime, rubble, and fresh soot, and be dug over with a fork before any planting is begun. Carnations Raby Castle and Duchess of Fife are free-flowering varieties of pleasing colour, strong in constitution and growth, and are excellent for beds or borders. Let the beds, &c., be formed well above the general ground level, when such varieties as the old Crimson Clove and Gloire de Nancy have to be wintered in the open air. Carnations that were planted out during the past autumn months in sheltered positions for early flowering should have the beds cleaned, the ground afforded a light dressing of fresh soot, and the surface pricked up; when dry, the soil should be made moderately firm about each plant.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as parcels of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—
Sale of Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY—
Compact Freehold Property, Highlands Nursery, Old Shoreham Road, Portslade, at The Mart, Tokenhouse Yard, E.C., by Protheroe & Morris, at 2.

MONDAY AND THURSDAY—
Herbaceous Plants and Bulbs, Lilinms, Azaleas, Ferns, &c., at 12; 1,000 Roses at 1.30, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

WEDNESDAY—
Perennials, Hardy Bulbs, Lilies, Gladiolus, Begonias, &c., at 12; 3,600 Roses, also Fruit Trees, at 1.30; Azaleas, Palms, Plants, &c., at 5, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY AND THURSDAY—
Unreserved sale of the whole collection of 9,000 Orchids, by order of Messrs. Hooley Bros., at Littleme Park, Southampton, by Protheroe & Morris, at 1.

FRIDAY—
Imported and Established Orchids, at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12 45.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich 40°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, February 19* (6 P.M.): Max. 53°; Min 42°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, February 20* (10 A.M.): Bar. 29·9; Temp. 51°; *Weather*—Overcast.
PROVINCES.—*Wednesday, February 19* (6 P.M.): Max. 51° Cornwall; Min. 43° Hull.

Larch Blister.

It is seldom an easy task to unravel the complex chain of causes that together are responsible for the existence of an epidemic disease, and the correspondence which has recently appeared in our columns clearly shows that the scourge of the Larch plantations in Britain is no exception to this rule. We have always to distinguish between the immediate and the contributory causes, and it is only when the nature of the latter comes to be understood that we can hope to grapple with the pest with much hope of ultimate success.

The organism that produces the Larch blister or canker was originally recognised by Willkomm, but the full history of Dasyscypha calycina, the fungus concerned, was first described by R. Hartig, who came to the following conclusions. The fungus can infect only through wounds. The infecting spores are produced in saucer-like fructifications which develop solely in damp air. The fungus attacks the living bark (including the bast) and cambium, and even penetrates the wood; but its advance is checked during summer when the intact bark-tissue is separated from the diseased cells by a specially manufactured layer of cork, while in autumn and winter the fungus evades the intervening cork and advances into healthy tissue. Hartig thus concluded that damp air and wounds are essential to the spread of the disease. As sources of injury he mentioned physical agencies and insects.

Mr. Massee suggested that species of Chermes were largely responsible for the wounds, and he succeeded in artificially infecting a Larch through such a wound. This mycologist's view was independently reached by Mr. Burdon, who worked as an entomologist. Mr. Carruthers was the only other British naturalist who communicated new ideas or facts, and he stated that infection could take place through unwounded organs.

We may take it as most probable that infection is accomplished mainly, if not exclusively, through wounds. But in discussing the evidence for and against Mr. Massee's view as to the part played by Chermes, it is necessary to take into consideration the conditions determining infection of a plant by a fungus.

In many, and probably in all, cases there is a struggle between a parasitic fungus and the host-plant that it attacks. On the one hand the fungus absorbs food from the host, pours forth ferments that dissolve the walls of the host's cells, and often, if not always, excretes poisons (toxins) that tend to paralyse the living protoplasm of the cells reached. On the other hand the host-cells often respond by efforts to shut off the fungus by ensheathing the fungal threads and its own walls with thicker cell-walls, or, as in the Larch, by producing obstructive layers of cork in the deeper intact cells; and the host-cell may employ chemical means of barring the progress of the parasite, by excreting various bodies noxious to the fungus and even paralysing its poisons.

It is therefore evident that the result of the struggle between the Larch and Dasyscypha will be decided by the relative strengths of the defence and attack. This in turn will be dependent upon the vigour of the individual Larch and the virulence of the individual Dasyscypha. Thus the constitution of the particular tree will partly decide the result, as is suggested by several of our correspondents. Furthermore, the prevailing external conditions may play a decisive part by favouring one combatant at the expense of the other. The high temperature during summer may give the tree the mastery and cause the quiescence of Dasyscypha, which wakes up when autumn and winter lull the Larch to rest; or it may be that these effects are due to other causes.

Now, in considering possible relations between the attacks by Chermes and Dasyscypha, it is necessary to distinguish three stages in the fungus attack: first, the arrival of the infecting spore; secondly, the initial infection; and, thirdly, the spread of the fungus within the Larch, all three of which may be determined by different sets of conditions. In general, attacks on trees committed by insects and fungi respectively are favoured by opposite conditions of humidity. Dry weather (and climate) favours the insect and is hostile to the parasitic fungus; dampness has the reverse effect. In this particular case dry weather, by preventing the manufacture or opening of the infectious fructifications, might give the Larch ample time to heal wounds made by Chermes. For this and other reasons, then, it would be quite possible for an abnormal attack by Chermes to take place in a dry season without any succeeding large attack by Dasyscypha, even if the fungus gained entrance only by wounds made by Chermes. This hypothetical case alone shows that arguments against Mr. Massee's view based upon lack of proportion between Chermes and Dasyscypha attacks lose much of their force. But, even supposing that after the heavy attack by Chermes the spores did gain entrance through some of the numerous wounds thus made, the vigour of the defence by the Larch might prevent proper infection, or might limit the growth of the fungus. Such cases of limited and localised infections are known to occur, for vigorous trees, though infected, may show no blister, and the emerging fructifications are the first obvious sign that the tree is diseased. Moreover, we have often seen Dasyscypha thriving on fallen twigs, so that it may at times be almost or entirely confined to the dead part or, at most, to the first infected living part of the bark of a living Larch. Such cases of incomplete attack might escape the eye of any but a specialist, and give rise to the possibly false impression that under circumstances apparently favourable to infection by the fungus, no such infection has followed a severe attack by Chermes.

On the other hand, as Sir Herbert Maxwell points out, even if there were a proportion between the attacks by Chermes and Dasyscypha, the two attacks may be the result of a common cause, namely, previous weakness of the Larch. Yet it may be replied that if in such paired attacks, the one by Chermes invariably preceded that by Dasyscypha, we should be justified in attributing the latter infestation, at least provisionally, to the former.

Though the evidence in favour of the view that Chermes is mainly responsible for the spread of Dasyscypha cannot perhaps be regarded as fully established, yet the view has considerable probability in its favour, and that probability has not been lessened by the discussion in our columns. The problem is one that deserves full investigation; indeed, the whole question of Larch blister requires investigation in this country, for the conditions under which it is rife or absent do not, in Great Britain, seem to accord with the conclusions reached by Hartig and the German foresters.

OUR SUPPLEMENTARY ILLUSTRATION.—Considering their somewhat stiff habit of growth it is surprising how effective, by careful arrangement, the various succulent plants may be made for summer bedding. As in Regent's Park (see Supplementary Illustration), a mound cut up by depressions for various depths will be found the most suitable place on which to display a collection of these plants. The larger-growing Agaves, Aloes, Echinocactus, and Yuccas occupy the higher and more prominent positions, the lower grounds being planted with Opuntias, Cereus, Echeveria, Crassula, and Cotyledon. A finishing touch is given by the judicious use of such carpeting plants as the Arenaria, Sedum, Herniaria, Sempervivum, and Antennaria. In arranging a bed of this kind the greatest care is necessary in order to avoid stiffness and formality; by adopting the mound system of planting and employing suitable carpeting plants a decidedly natural and pleasing effect may be brought about. It may be of interest to state that in the bed at Regent's Park of which an illustration is given, about 90 species and varieties of succulents are used, the total number of plants in all being 7,650. The other picture in the illustration affords a view of a large flat bed at Hampton Court, and planted with a miscellaneous collection of low-growing species, relieved with occasional "dot" plants.

ROYAL HORTICULTURAL SOCIETY.—The fortnightly exhibition of flowers and fruit will be held at Vincent Square, Westminster, on Tuesday, March 3. At the afternoon meeting of the Fellows a lecture on "Bulbous Plants in New Zealand" will be delivered by Mr. E. WHITE.

———An examination in elementary horticulture for lads and young men under 19 years of age will be held under the auspices of the Royal Horticultural Society on Wednesday, March 25, in as many different centres in Great Britain and Ireland as circumstances may demand. The general conduct of this examination will be on similar lines to that of the more general examination. Intending candidates may obtain a copy of the syllabus from the secretary, Royal Horticultural Society, Vincent Square, London, S.W.

SURVEYORS' INSTITUTION.—The next ordinary general meeting of this society will be held on Monday, February 24, 1908, when a paper on "The Small Holdings and Allotments Act, 1907," will be read by Mr. W. G. S. ROLLESTON. The chair will be taken at 8 o'clock. The annual dinner of the institution will take place on Wednesday, February 26, 1908, at 7 p.m., at the Whitehall Rooms, Hotel Metropole.

NATIONAL CHRYSANTHEMUM SOCIETY. The fourth annual dinner inaugurated by this society in conjunction with their exhibition of market varieties of Chrysanthemums will be held at Lyons' Café, 200, Piccadilly, W., on Monday, February 24, at 7 p.m. The chair will be occupied by Mr. R. BALLANTINE.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.—We warmly congratulate the authorities of this charitable institution, and gardeners generally, on the legacy of £3,000 bequeathed to the institution by the late Mrs. JOHN RYLANDS, who has left a sum of £473,000 to public institutions and charities. The interest on £3,000, even at 2¾ per cent., is sufficient to maintain four male pensioners in perpetuity.

THE GERMAN DAHLIA SOCIETY.—This society has celebrated its 10th anniversary by bringing together in a dainty *brochure* the principal events that have happened in connection with it since its foundation in 1897. Shows have been held every year, and it is pleasant to be able to congratulate the society on its success, for only in one year did the budget show a deficit. The membership has steadily increased from 80 in 1898 to 131 in 1907. A good feature of the report is the inclusion by name of all the varieties of Dahlia raised by German growers. We heartily wish the society continued prosperity.

LEGACY TO A GARDENER.—It is reported that Lord BATTERSEA, who died in November last, bequeathed £100 to his gardener, a similar sum to his butler, and a life annuity of £60 to his valet, and one year's wages to each servant in his employ.

EFFECTS OF FOG ABROAD.—We often hear complaints of the evil effects of urban fog on the vegetation that exists in and around our great centres of population; but we do not suffer alone. According to a writer in *La Tribune Horticole*, the dense fogs that have prevailed in Belgium have done an immense amount of damage to plants under glass. Brussels has suffered badly, and the buds of Cattleya, Lælia, Dendrobium, and other Orchids have shrivelled without opening; whilst the forced Lilacs shed their blossoms in showers while being cut for the market.

CHEMICAL FIXATION OF NITROGEN.—The question of the utilisation of the atmospheric nitrogen is one of overwhelming importance, not only to those engaged in horticulture and agriculture, but to the whole human race. It is known, of course, that certain lowly plants working under suitable conditions can perform this task, and there have been various other methods that have been invented by chemists for the same object. The best known of these is perhaps the electrical one, utilising the energy of waterfalls for the purpose. But the upkeep of the plant is apparently so heavy as to make the method anything but certain from a commercial point of view. It is with interest therefore that we learn of another way of oxidizing the nitrogen by means of steam and heated coke. The details of the process are not yet made public, but the results look hopeful, both on the score of cheapness and practicability.

THE LATE JOHN BOOTH.—We are informed that Herr JOHN BOOTH, whose death was recorded in our last issue at his country seat near Berlin, came of a Scotch family, his grandfather, JAMES BOOTH, having emigrated in 1798 from Scotland to a village near Hamburg, where he founded the well-known nurseries, which were kept up through three generations till 1884. JOHN BOOTH, after having given up his business, moved to Berlin and devoted himself entirely to a work already begun by his father, namely, the introduction of valuable exotic trees from North America into the German forests. Foremost among them was the Douglas Fir, on which he had published his first book in 1877. He gained powerful support from Prince BISMARCK, who raised large plantations of Douglas Fir in his forest at Friedrichsruhe. In 1896 JOHN BOOTH published his second book on the North American Trees and their Adversaries, and in 1903 a further work on the Introduction of Foreign Trees to the Prussian Forests under Bismarck. That the Douglas Fir now holds a prominent place among German forest trees is largely due in the first instance to the activity of JOHN BOOTH.

THE PARIS FLOWER TRADE.—The flower trade of Paris is one of the largest of its kind in the world, owing to the wealth of floral decoration employed by its citizens. According to a writer in our contemporary, *Le Jardin*, more than 200,000 flowering plants daily arrive at the City Market, and this is exclusive of the enormous supplies of cut flowers. The plants are grown partly on the outskirts of Paris itself, and partly in the surrounding country districts. Some 200 growers, who altogether occupy about 150 hectares (370 acres) of ground, of which one-third is under glass, send the whole of their produce, to the annual value of about 5,000,000 francs, into the city. This is exclusive of the forced Lilacs from Vitry, and the Roses from La Brie, which account for another million and a half francs. Other towns contribute cut flowers to about the same value. In addition, some 30,000,000 plants in pots are annually received from these sources, besides the large quantities of Camellias, Roses, Azaleas, &c., which arrive from more remote districts. An immense number of bulbs, Orchids, and other exotics are also imported from foreign countries, swelling the large amount already indicated to a truly huge total.

LETTERS FROM CHINA.—Professor SARGENT has again kindly favoured us with extracts from a letter received from Mr. E. H. WILSON. It is dated December 12, 1907. "Among the more interesting of the last seeds sent are those of two Catalpas (fruit 2½ feet long), a new Pterocarya in addition to P. hupehensis and P. Paliurus, a new Cedrela, two new Celtises, the hairy Davidia, the Tulip-tree, a Walnut with a spinescent endocarp, Cercis racemosa, a Beech, many Maples, Roses, Euonymus, Celastrus, Oak, Chestnut, &c. The Oaks and two-leaved Pines will yet turn me gray, and I'll leave them aside for the moment. The Chestnuts (sweet) are very interesting. I have all forms from the shrub 1½ to 3 feet, with its tiny nuts, to trees 50 feet high. One form which evidently produces a single acorn-like nut of excellent flavour is perhaps the finest of all. That all the Chestnuts hereabout are mere forms of one species is difficult to believe. Considering how largely I collected here in 1900-1901 for Messrs. VEITCH, I am astonished at the results to date. As illustrating this I may cite Vitis. I know not how many kinds I sent Messrs. VEITCH, yet this year I have eight to ten species I never met with before. As a set-off against this it must be mentioned that I have failed to rediscover many plants, but by a remarkable coincidence nearly all of these are already in cultivation with Messrs. VEITCH. Heretofore I have assumed the large Abies on the mountains north of Ichang to be the same as the one in the far west. In this I was wrong. The Hupeh species has light brown or gray-coloured cones, the western species dark violet-purple cones. I have only been able to secure about 50 good cones and a rather small quantity of seed. There are many thousands of trees, but cones are very scarce this year. However, in 1901 I failed to secure a single cone or seed. Dr. HENRY, too, failed in the same respect, though, I believe, Père FARGES succeeded. The herbarium collection is much finer than anything I have got together before, being replete with fruit, seeds and barks. The collection of barks I find of great interest, and I believe will prove of systematic value especially in variable and composite species. For example, many of the forms of Quercus variabilis are readily distinguishable by the bark alone. One of the finest forms of this species has a magnificent corky bark over 1 inch thick."

NITROGEN FOR PLANT GROWTH.

THE question of the plant's supply of nitrogen is one of the most interesting of the plant-food problems of the day, and is possibly the least understood. A large proportion of the fabric of all plants consists of nitrogenous material, and this portion of its structure is of fundamental importance to its well-being.

Further, it is upon the nitrogenous matter of plants that animals depend for the proteid material—blood, flesh, &c.—since animals can only utilise for this purpose nitrogenous material already elaborated in the tissues of plants or in the bodies of other animals.

SOURCES OF NITROGEN.

Plants may absorb their nitrogenous food in two ways, either by means of their leaves from the free nitrogen of the air, or from the ammonia gas or the nitric acid, by means of their roots, from the stores within the soil.

With regard to the first of these, the absorption of free nitrogen by means of the leaf, the question cannot, perhaps, be said to be definitely settled even yet, though the general trend of scientific opinion is to the effect that no such absorption and direct utilisation by the green plant takes place.

With regard to the second of these problems, the assimilation of plant-food from the soil, it is known that plants obtain their nitrogen almost entirely in the form of nitrates dissolved in the water of the soil. These nitrates, as they are formed by the soil-germs, combine either with lime to make nitrate of lime, or with potash to make nitrate of potash, when they become easily

available plant-foods, and can be taken up by plant-roots as required.

Soda, to some extent, may take the place of potash or lime. The Rothamsted experiments show that when nitrate of soda is used as the source of nitrogen supply, an application of potash is not always necessary, but when sulphate of ammonia is used as the source of nitrogen supply, then potash must also be applied, and at frequent intervals a dressing of lime also.

FORMATION OF NITRATES IN THE SOIL.

It has long been known that the addition to a sterile soil of a quantity of a more fertile one rendered the sterile soil fertile and productive; and the operation of top-dressing poor soils in this manner has been practised for ages.

Science reveals to us the fact that this increase in fertility is accompanied by an increase in the quantity of nitrates in the soil, and that this is brought about through the agency of the soil-germs or bacteria.

Professor E. Henry (see *Trans. Sac.*, 1898) found that decaying leaves of forest trees, such as Oak or Beech, possess the power of fixing the free nitrogen of the air in considerable quantities. The fallen foliage on the surface of the ground in an oak forest was found to have accumulated about 11½ lbs. of nitrogen per acre, and in the case of Beech tree leaves 19¾ lbs. of nitrogen per acre was annually accumulated.

This enriching of the soil in nitrogenous material or nitrates is due to the effect of the living organisms of the soil working upon the decaying leaves which supply the carbohydrates necessary to enable them to absorb and utilise the free-nitrogen of the air.

Manures such as dried blood, farmyard and stable manure, seaweed, &c., owe their great value as plant-food to the fact that their nitrogen is converted into soluble nitrates through the agency of the soil-germs.

These ceaseless workers attack the humus matter which is derived from the vegetable and animal remains left in the ground. They attack all manures applied to the soil, and their combined efforts result in the purification of soil and air, and in the manufacture of suitable plant-food

It is also bacterial germs, in all manner of shapes and groupings of individuals, that attach themselves to the roots of the leguminous family Clovers, Beans, Peas, Lucerne, &c.—and by their work at the roots take the free nitrogen of the air which exists in the interstices of the soil and convert it into nitric acid.

We know now with practical certainty that nitric acid, and, therefore, nitrates cannot be formed in the soil without the work of bacteria germs, and it may be—for our present knowledge and reasoning of the subject seems to point in that direction—that we shall find that every process in nature in the breaking down and in the building up of plant-food; in fact, that all the varied processes that are taking place in the soil for the growth of crops are brought about by the agency of these living organisms which are continually at work. The soil is both a store-house of plant-food and a laboratory in which that food is manufactured into such a form that crops can use it.

The soil may be ever so rich in the raw material necessary for conversion into plant food, but if the little chemical manufacturers be not present in sufficient numbers, or be weak in vigour, through lack of pure air, potash, or lime, there will not be a sufficient store of finished food products awaiting the searching root-fibrils of the growing crops.

THE NEED OF AIR AND MOISTURE.

A gardener cannot control the amount of sunlight and rain that falls on his land; but, by his horticultural methods, he can do a great deal to atone for the deficiencies of climate.

Thorough and skilful cultivation will, in a cold season, help to preserve the warmth in the soil, and in a hot season it will help to check the too rapid evaporation of the small amount of moisture that there may be in the soil during such periods.

Thorough cultivation will also enable the surface air and moisture, warmed by the heat of the sun, to penetrate around the soil particles, and it will enable the roots of the plants with greater ease to penetrate and take up the plant-food which has been made soluble by the soil-germs. *J. J. Willis, Harpenden.*

FIG. 49.—PEAR BLICKLING; A LATE VARIETY OF FIRST-CLASS QUALITY.

(For text see page 123)

PEAR BLICKLING.

THE varieties of late Pears of first-class quality are not numerous, and any addition that helps to prolong the season when these valuable fruits are available must be welcomed, and especially when, as in the case of the variety under notice, it combines the very highest excellence of flavour with late keeping. In January of last year Mr. Allan, of Gunton Park Gardens, submitted to the Fruit Committee of the Royal Horticultural Society a Pear which he had discovered growing in the gardens at Blickling Hall. This pear no one appeared to know by name. The Committee recognised in the fruits a new variety of high merit, and, after naming it Blickling, they unanimously conferred upon it an Award of Merit. We are indebted to Mr. Allan for the opportunity of figuring this new Pear, which has been aptly described as a late Doyenné du Comice, for it is of delicious flavour. Mr. Allan is of opinion that it is quite the best-flavoured Pear in season in January, and when at its best equals Doyenné du Comice in both flavour and other good qualities.

NOTES FROM A FRENCH GARDEN.

THE preparation of the hot-beds for frames and lights is nearly finished, and the first beds were started on January 15; breakfast Radishes and forcing Carrots were sown first, and Cabbage Lettuces (Little Black Gotte) were planted a few days later; all are now growing nicely. The Radishes already show the first leaf, and in many cases will be ready in the course of 10 or 12 days. The first Carrots (Little French) are just showing the seed leaves. The small Lettuces, which were sown on October 1, and pricked off a few days later under the bell glasses or cloches, when just big enough to be handled, have done well here this winter, as we have had no fog. Now in the damp hot-beds they have formed a little heart, and we are much pleased with them. This week we have had to look through the beds to remove the oldest leaves from the Lettuces, as the ground must always be kept very clean.

The weather has been so mild that the Radishes have become drawn, but we cannot admit air, as this would be prejudicial to the Lettuces.

We have sown our first batch of Melons, an improved strain of the Cantaloup Fond Blanc de Paris. The seeds were sown in small trays just as Cucumbers are sown, and they germinate in the Cucumber house as this saves making up a hot-bed. We shall pot them up into 60-size pots when big enough, using very good loam, and when they have become nicely rooted they will be put in a hot manure bed prepared a few days beforehand.

On February 12 we started the hot-beds for Cos Lettuce Green Paris; these were sown and grown like the Cabbage Lettuces until the middle of November, when they were given more room by transplanting.

We grow one Cos Lettuce under each cloche or bell glass, and three Cabbage Lettuces (Little Black Gotte) in the first batch only; they are set in a triangle round the Cos.

There are three rows of cloches per bed, 42 in each row, set alternately in the rows.

We plant nine rows of Cos Lettuces, the cloches covering the plants in the 2nd, the 5th, and the 8th row respectively. When this first batch is marketed at the beginning of April we shall plant Cauliflowers "Briancourt" in the place of the Cos Lettuces, and cover with the cloches the 1st, the 4th, and the 7th row of plants, which are by then half-grown. When they are ready to cut we shall shift the cloches on to the 3rd, the 6th, and the 9th row, and by the middle of May this third batch will be cleared, leaving the necessary space for the Cauliflowers. *P. A., Mayland, Essex, February 14.*

LAW NOTE.

RAILWAY RATES.

MR. JUSTICE A. T. LAWRENCE, the Hon. A. E. Gathorne-Hardy, and Sir James Woodhouse—the Railway and Canal Commission—on the 4th inst. heard an application by the Mutual Transport Co., of Guernsey, which was formed for the purpose of conveying fruit produce to the mainland, and by Mr. W. Entwisle, a Guernsey fruit grower, for a through rate between Newhaven and London, Birmingham, Manchester, and Leeds. They alleged that, by the present rates charged for the carriage of fruit, the French grower who sent his fruit to the same market via Dieppe and Newhaven was unduly preferred and the Guernsey grower unduly prejudiced. The defendant railway companies—the London, Brighton and South Coast, and the London and North-Western—denied that there was any undue preference or prejudice. The case was argued in November last, and then came up for judgment on the 4th inst.

Mr. Justice A. T. Lawrence, in delivering judgment, said there were two items complained by the applicants—first, the charge made for the conveyance of French Tomatos from Dieppe to Newhaven, and, secondly, the land carriage from Newhaven, it being alleged that the difference was 7s. 4d. per ton from Newhaven to Birmingham in favour of the foreign produce. As to the first point, it resolved itself into a complaint that the freight charged for French produce by steam vessels belonging to the Great Western Railway of France, but in which the London, Brighton and South Coast had some interest was too low, but the arrangement had been in existence for 40 years, and had been found to work satisfactorily, and he could not see that, in this matter, there was any undue preference of the foreign produce. As to the land carriage, the difference of charge was admitted by the defendants, but they said it was due to the difference in the system of packing adopted respectively by the French growers and the Guernsey growers. The French packed their fruit in cases, and the Guernsey growers packed theirs in baskets with cross handles, and larger at the top than the bottom, the result being that double the weight of French fruit could be got into a railway truck as compared with the Guernsey produce. If, said the defendants, the Guernsey growers would pack their fruit in cases, like the French, they would carry it at the same rate. Under all the circumstances, he found it impossible to hold that any undue preference of the French grower, or any undue prejudice to the Guernsey grower, had been proved. The other Commissioners concurred, and the application was accordingly dismissed.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

A SUSSEX WASTE.—I am surprised that anyone can be found in this democratic age to openly advocate the enclosure of common land. However badly the land is used or not used at the present time, to take it away from its present owners would be nothing short of robbery. I am glad to hear that the commoners are active in defending their rights, although their methods may be rough; possibly if they had the means they would be more polite and go to law, but, being poor men, they must be content with primitive methods. Acting on the principle, "Unto him that hath to him shall be given, and from him that hath not shall be taken away even that which he hath," the rulers of our country have sanctioned numerous Enclosure Acts, with the result that the land has gradually been filched from the commoners, whose living it was, to be added to large estates. It is true that compensation was given in most cases, but only the one generation of commoners got it; and their descendants, who had as much right to the land as their predecessors, found themselves bereft of their ground and left with nothing to show for it. Even when the commoner had a little piece of land given to him by way of compensation, it was soon sold and lost to posterity. Because the commoner is too poor to bring his land into cultivation is no reason why it should be taken away from him; rather he should be helped to make a start on it. If land is running to waste, and no one who has the right can or will cultivate it, then the only fair thing to do would be for it to fall to the State. The State, in such a case, could enclose it and do one of two things with it. If the land were only fit for afforestation, the State could plant it and divide it up, giving the commoners the first chance of taking over the improved portions at a low rental to recoup the State for its work. If the land were fit for agricultural operations, the State could put it into working order and proceed as with the afforested land. In this way the commoner would get the full benefit of his rights, and would be unable to sell his allotment. His descendants would again get first choice, and in the event of their not caring to take the land or there not being any legal descendants, the land would go to anyone who cared to become the State's tenant, on condition that the cultivation was carried on. This condition would be necessary to prevent the land being gradually allowed to run wild for sporting purposes. This may be a Utopian idea; but we can give a Land Purchase Bill to Ireland, why not assist our own people for a change? I think, if Mr. Simpson had a horse and cart given to him in order to assist him to live, and happened to become too poor to keep his cart well painted and cleaned and the horse well fed, he would think it very unjust if some rich neighbour stepped in and took it away from him, because he could keep it up better and prevent its becoming an eyesore to the public. Yet this is a parallel argument to his. Before people recommend the enclosure of common land, let them consider the significant fact that our Poor Laws date from the first Enclosure Act. *Wilfrid M. Bear.*

CALCEOLARIA PINNATA.—I was much interested to read, in the article on "Calceolarias," p. 88, by Mr. J. Douglas, of the appearance of C. pinnata in a Surrey garden. This species appeared in these gardens in a part of a rock-garden devoted to Orchis in the same year and in the same strange manner as Mr. Douglas describes. The bed had been made from loam cut on the estate and peat from moors situated a few miles away, so that the seed could not have been introduced in the new soil. No seeds of any kind were sown, nor were any new plants placed within several feet of the spot where they appeared. Calceolaria pinnata, as far as I can learn, has never been seen in this district before. *F. C. Puddle, Scampston Hall Gardens, Rillington, York.*

R.H.S. MEETINGS AND BANK HOLIDAYS.—The very reasonable request made by Mr. W. Cuthbertson at the recent annual meeting of the Royal Horticultural Society for greater consideration being shown to those trade and garden workers who, because meetings have followed close on Bank Holidays, were perforce kept at work on those days, instead of getting a holiday like the rest of their fellows, merits kindly consideration. The excuse made for holding meetings on the Tuesdays succeeding Bank Holidays was that, as the meetings had to be fortnightly, such an arrangement could not be avoided. But the fortnightly rule has exceptions, for instance, the present interval between the last and next meeting is three weeks. By that longer interval there will be no meeting on Easter Tuesday, but there will be meetings on Whit Tuesday and the day following August Bank Holiday. This last might easily have been avoided, and no one would have complained had there been an interval of three weeks between the shows at that season. It would also have avoided holding a meeting in the great Shrewsbury show week, another matter worthy of consideration. *F.R.H.S.*

WHAT IS AN HERBACEOUS PLANT?—The interesting discussion of this subject shows how difficult it will be for persons concerned with the management of exhibitions to come to a common agreement upon the question, and the need is pressing for some definite rule on the subject to be adopted by all societies and judges. The difficulty has often impressed itself upon me, not only when judging, but when visiting flower shows as a spectator. I can recall one instance in which a judge passed over a good stand in a class for "hardy herbaceous flowers" because it contained two Lilies. I do not think he was justified in doing this. In another case, where shrubs were excluded, a prize was given to a stand which included a shrubby Hypericum. The exhibitor, on being taxed with this privately, said: "Oh, it's only a sub-shrub!" So far as I have observed, the best solution of the wording suitable for a schedule has been "Hardy border flowers—shrubs and annuals excluded." This, however, as will be seen from the circumstance just noted, is far from being a perfect wording. I have seen a bunch of Dimorphanthus mandshuricus shown in such a class, and the stand received a second prize, the judge probably being unaware of the nature of the flower. A class for "Hardy border flowers—shrubs and annuals excluded" admits biennials, and some difficulties arise here. Is an Antirrhinum grown as a biennial to be admitted or excluded? At an autumn show is the same flower, treated as an annual, to be allowed? Strictly speaking, an Antirrhinum is a perennial, but it is not so everywhere. Many other instances of difficulties have been quoted, such as Phygelius capensis, which with me is a shrub, but in some other persons' gardens is an herbaceous plant. It is, of course, easy to offer destructive criticism of the present methods of judging and the present wording of schedules, but when constructive work in the way of offering suggestions for an improvement upon the present method or want of method is considered, many difficulties are met with. A possible basis of agreement might be arranged by requiring "Hardy border flowers—shrubs, trees, and annuals excluded,' leaving some responsible body like the Royal Horticultural Society to take up the interpretation of the latter proviso, and to issue a short list of the nature of an *index expurgatorius*, ruling out certain things occasionally shown as coming under the schedules, but which are, strictly speaking, either shrubs or not hardy. The difficulty of drawing up such a list is certainly great, but, after all, I do not think that it is much greater than the "too much alike" lists in, say, fruits, Sweet Peas, or other plants. It might be limited to the subjects which present much difficulty, such, for example, as the Phygelius. Such a list would probably be accepted by the leading provincial and other societies, and would serve a most useful purpose. The question of hardiness might be solved in a similar manner, taking as a basis the plants hardy under average conditions in the United Kingdom, and issuing a list of those which are on the border line only. *S. Arnott.*

PARSLEY IN WINTER.—This simple herb sometimes gives the gardener more trouble and anxiety than any other crop. It was my lot for over 20 years to provide a more or less supply daily without intermission. Like most gardeners, I planted some in frames annually, mainly in order that it might still be available in snowy weather. When the supply ran short in spring, we have tided matters over more than once by keeping the lights closed and applying a lining of fermenting materials. Having some spare lights 10 feet long, these were put over a breadth of Parsley on a south border. The lights were laid on pieces of quartering resting on bricks sufficiently high to clear the Parsley. The lights were put on early in the autumn to throw off the rain, for in this district Parsley and many other plants seem to suffer more from a heavy rainfall on retentive soil and from an excess of atmospheric moisture than from frost, which is often more severe in the Midlands and even further south. The Parsley will sometimes die off in frames at any rate, it has done so with me. This may be perhaps for want of sufficient ventilation, but I never lost any under such a covering as I have described. *W. P. R., Preston.*

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

FEBRUARY 11.—*Present:* Mr. E. A. Bowles, M.A., F.L.S. (in the Chair); Rev. W. Wilks, Dr. M. C. Cooke, Dr. A. B. Rendle, Prof. G. S. Boulger, F. D. Godman, W. B. Hemsley, H. T. Güssow, W. C. Worsdell, A. W. Sutton, W. Hales, L. H. de B. Crawshay, G. S. Saunders, H. J. Elwes, J. T. Bennett-Poë, C. T. Druery, G. Gordon, W. Cuthbertson, J. Douglas, and F. J. Chittenden (secretary).

Red Currant twigs twisted.—Mr. H. T. Güssow showed shoots of Red Currant twisted and curled at the tips, arising from the confinement of the young growths under nets.

Microloma linearе.—Mr. J. O'BRIEN sent specimens of this uncommon Asclepiad, showing how it climbs over bushes in its native home in South Africa. The plant was figured some time ago, but is very rare in cultivation.

Bigeneric Orchid hybrid.—Sir JEREMIAH COLMAN showed a hybrid raised between Diacrium bicornutum and Cattleya intermedia alba (see fig. 45, p. 114). The colour of the Diacrium had been almost entirely lost except for a tinge of sulphur in the labellum. The parent species are usually regarded as being widely separated in natural relationship, but a hybrid between D. bicornutum and Lælia cinnabarina was awarded a Botanical Certificate on March 14, 1905.

Nomenclature of hybrid Orchids, &c.—Some discussion took place with regard to the naming of hybrids between species assigned to two or more genera. The general opinion was that such hybrids should, when raised between plants belonging to two different genera, have the names of both genera indicated; but where the progeny was the result of crossing a bigeneric hybrid with a plant of another genus altogether, a purely conventional name should be assigned, preferably with a distinctive termination. The further discussion of the matter was adjourned to another meeting.

Diseased Sweet Williams.—Lady HOPKINS, of Romsey, sent Sweet Williams in a dying condition, with pale brown spots upon their leaves, which were due to the attacks of the fungus Puccinia dianthi. This fungus frequently proves fatal to the Sweet William, and the infection is said to be carried in the seed, so that whole batches are killed. The particular variety in the present case was "Pink Beauty," and the present is the second year in which the trouble has occurred, though in different spots in the same garden.

Insects on Oleander, &c.—Mr. G. S. SAUNDERS reported that he had examined the insects found upon various plants in a greenhouse, and sent by Mr. STANTON BROWN, A.R.H.S. They belonged to the family Psocideæ, and were specimens of the uncommon species Cæcilius Dali. This species is not known as plant pests, but are said to feed upon fungoid matter of various kinds, mould on palings, and rust fungi on leaves, &c. They are most frequent upon the bark of trees.

ROYAL GARDENERS' ORPHAN FUND.

ANNUAL MEETING AND ELECTION OF CANDIDATES.

FEBRUARY 14.—The 21st annual meeting was held at Simpson's, Strand, on the above date, Mr. Henry B. May, Chairman of the Committee, presiding. The attendance of subscribers was rather below the usual number, due doubtless to the fact that the Fund is so admirably controlled by the Committee, so that no loophole for adverse criticism seems open.

After the minutes of the previous annual meeting had been read, the Chairman suggested that the Report of the Executive Committee for 1907, with the balance-sheet, printed copies of which were in the hands of all present, should be taken as read.

REPORT OF THE EXECUTIVE COMMITTEE.

In presenting their Twentieth Annual Report, which practically brings the official record of the operations of the Fund since its establishment up to its twenty-first birthday, the Committee most heartily congratulates all past and present supporters on another year of steady progress and increasing prosperity and usefulness, and on a record of good work accomplished during the twenty years of the existence of the Fund, such as none could have anticipated, who, in the early months of 1887, took part in laying its foundation.

At the end of the first year a very modest start was made with the election of eight candidates at a cost of £139 15s. At the end of 1907, the number of children in receipt of the full allowance, granted after election, was 95, while nineteen others were receiving much-needed financial assistance while waiting for advancement to the full pay list, the total amount distributed during the year being £1,511 10s., or £100 more than the previous year's total. At the commencement of 1907, there were 95 children receiving the full allowance, and nineteen were added to the list at the Annual Meeting in February, bringing up the total number of orphans elected during the twenty years to two hundred and thirty-six, while the total sum expended in allowances and grants in aid during the same period amounted to no less a sum than £17,884 12s. 6d. The total amount of the receipts from all sources up to the end of 1907 is £20,884, to which, besides providing the large sum distributed in accordance with the objects for which the Fund was established, has enabled the Committee to provide a Reserve Fund of over £11,000, all well invested, and the dividends accruing from which more than provide for all necessary working expenses.

As regards the accounts of the past year, which show an increase in receipts over 1906 amounting to £69 18s. 10d., an increase of £100 in the children's allowances, an addition of £120 16s. 11d. to the amount invested in Consols, an addition of £50 to the Deposit Account, and a larger sum carried forward; the Committee have again to deplore the one weak spot, *i.e.*, the

P. RUDOLPH BARR,
M. ROWAN, } *Auditors.*

February 3, 1908.

comparatively small sum received in the form of annual subscriptions, and once more most earnestly appeals for a larger measure of support under this heading.

Under the genial, and so happily appropriate, presidency of "the children's Lord Mayor," Alderman Sir William P. Treloar, Bart., the annual Festival Dinner held at De Keyser's Royal Hotel, E.C., on May 23rd, was again both socially and financially an unqualified success, the Chairman's list for the second time in the history of the Fund exceeding £1,000, while the attendance of friends and visitors was also larger than heretofore. In commending the claims of the Fund to generous support, Sir William remarked that "the work done was beyond praise, and it was a terrible thing to be left destitute, so that it was the bounden duty of all to assist those children whose unhappy lot it was to be left without parents or money," and so satisfactory a response must have been as gratifying to Sir William Treloar as it was to your Committee, and they gratefully tender to him their hearty and most cordial thanks, at the same time inviting the subscribers at the Annual Meeting to join them in marking their sense of his kindness by electing him a Vice-President.

With the utmost possible satisfaction the Committee make the announcement that in order to fittingly celebrate the coming-of-age of the Fund, the noble President, the Duke of Bedford, K.G., has most kindly consented to preside at the forthcoming festival, which has been arranged to take place at the Hotel Cecil on Tuesday, May 12th, when it is earnestly hoped that all friends and supporters will unite with the Committee in their efforts to render the festival worthy of such an auspicious occasion.

The warmest thanks of the Committee are again most heartily accorded to all who have assisted in promoting the welfare of the Fund during the past year, and especially is grateful acknowledgment due to the Right Hon. Mary, Countess of Ilchester, Sir Frank Crisp, and Major John W. Dent, for so kindly opening their private gardens to the public in aid of the charity, to the Stewards at the annual dinner, the Honorary Local Secretaries, and the many good friends in such centres as Altrincham, Chesterfield, Bradford, Reigate, Chislehurst, &c., who have again sent up most acceptable contributions.

With very sincere regret the Committee records the fact that the Fund has suffered grievous losses during the year by the lamented deaths of so many constant and valued supporters. From the rôle of Vice Presidents the names of Lord Battersea and Dr. Maxwell T. Masters, F.R.S., will be greatly missed. Lord Battersea will be specially remembered for his graceful advocacy of the claims of the charity to the support of all lovers of Horticulture at the annual dinner in 1900, while Dr. Masters from the inception of the Fund had whole-heartedly supported it in every way, and specially rendered most valuable assistance in the drafting of the rules which, largely owing to his sagacious counsel, have since been found to work so smoothly. Very deeply indeed do his old colleagues deplore the loss of Mr. John Assbee, who for nineteen years was one of the most regular attendants at the meetings of the Committee, and an enthusiastic and sympathetic worker, and who, by his admirable organisation of the splendidly successful floral displays held in Covent Garden Flower Market in 1888 and 1889, so largely helped to increase the size of the "nest egg" of those early days. Very keenly felt also is the death of Mrs. Charlotte Head, widow of Mr. W. G. Head, a former active member of the Committee, and who, since her husband's death, had been an enthusiastic collector for the Fund, and in a few years raised a sum amounting to nearly £150. Other supporters whose contributions will be greatly missed were Miss Ann Hayes, Mr. J. F. Blackwell, J.P., Mr. Charles Kauffman, Mr. James H. Veitch, and Mr. George May.

During the year the Committee has again been much gratified by the generous assistance rendered to the Fund and the keen interest taken in its management by the Treasurer, Mr. Edward Sherwood, who is hereby most gratefully thanked, and very cordially nominated for re-election.

The members of the Committee who retire by rotation are Mr. W. R. Alderson, Mr. George H. Barr, Mr. George H. Cuthbert, Mr. William Howe, Mr. John Lyne, Mr. William Poupart, Mr. Thomas W. Sanders, and Mr. William P. Thomson, and, all being eligible, offer themselves for re-election. For the vacancy created by the death of Mr. Assbee, the Committee has great pleasure in recommending the election of Mr. Edward Parsons, of Messrs. Parsons and Co., Ltd., Fruit Market, Covent Garden, a gentleman who for some years past has been a generous supporter of the charity, and a regular attendant at the annual festivals.

The Auditors, Mr. M. Rowan and Mr. P. Rudolph Barr, are again most cordially thanked for the carefulness with which they have made the annual examination of the accounts, a duty most cheerfully rendered, though annually making a greater demand upon their time owing to the steady growth of the institution. Mr. Rowan, who has regularly examined the accounts for thirteen years, is the retiring Auditor, and his unique knowledge of the books and the general trend of the Fund's operations makes him a too valued colleague to part with. He is, therefore, with much pleasure recommended for re-election.

In moving the adoption of the Report and Balance-Sheet, Mr. May remarked that nothing unusually eventful had occurred during the year. The Fund had received generous support, and the Committee hoped that this support would be given in an increasing measure. Most pleasant was it to read letters from mothers of orphans, written in high appreciation of the Fund's kindly help to them through their children. The members of the Committee had worked hard, and merited all praise and thanks.

At the first election eight pensioners were put on to the Fund. Last year they finished up with 95 orphans, and they had in the 21 years given help to 236 orphans. The annual Festival had been a great success, and their warmest thanks were due to the ex-Lord Mayor, Sir W. Treloar, Bart., for his generous help. Mr. May then read a letter from a lady, giving an excellent account of the progress in life made by certain orphans who, having benefited by the Fund, had now gone out into the world, filling good situations. He also read an interesting letter from Mr. H. J. Clayton, formerly of Grunston Park Gardens, Tadcaster, in which he suggested that an effort should be made to raise a sum of 10,000 shillings as a birthday offering to the Fund.

Mr. W. Marshall briefly seconded the motion, and, no further remarks being offered, the report was adopted.

Mr. W. Poupart proposed, and Mr. Bull seconded a cordial vote of thanks to Sir W. Treloar for his generous assistance to the Fund in presiding at last year's annual dinner. Mr. W. Roupell proposed and Mr. Lyne seconded the re-election of Mr. E. Sherwood to the office of treasurer, with thanks for past services. Mr. Caselton moved, and Mr. Gordon seconded, the re-election of Mr. M. Rowan as auditor, and thanking him also for efficient services.

Mr. A. Dean moved, and Mr. McLeod seconded, the re-election on to the committee of Messrs. W. R. Alderson, G. H. Barr, G. H. Cuthbert, W. Howe, J. Lyne, W. Poupart, T. W. Sanders, and W. P. Thomson, also giving them cordial thanks for past labours. Mr. B. Mansells proposed, and Mr. G. H. Cuthbert seconded, the election of Mr. E. Parsons, of Covent Garden, on to the committee, to fill the vacancy created by Mr. Assbee's lamented death.

The Chairman proposed the re-election of the secretary, Mr. B. Wynne, to his office, and spoke in high terms of the efficient services he had rendered to the Fund. Mr. W. Bates seconded the motion, which was carried unanimously.

Result of the Election.

At 4.30 p.m. Mr. Poupart, on behalf of the scrutineers, announced the result of the election as follows:—

	Votes.
Percy E. S. Warwick	377
Lucy M. Claxton	367
Alice Arnold	361
Herbert E. Smithers	358
Jeanie M. Lamond	353
John H. McCullum	322
Edward John Ward	294
Hilda A. E. Tickner	257
Bessie Seaman	221
Thomas H. Thomas	182
Ethel M. Blackmore	133
Dorothy Wiggins	130
William H. N. Mullens	127

Non-Elected.

Violet G. Randall	102
Reginald G. Grist	84
Alice R. Gascoigne	71
Ellen Ashton	60

The Chairman declared the first 13 candidates to have been duly elected.

Mr. H. J. Veitch then made an earnest appeal to the Committee, if in their power, to put the remaining four unsuccessful candidates on to the Fund, especially as it would be a graceful way of celebrating the 21st year's work of the Fund. Mr. T. W. Sanders cordially supported the proposal. The Chairman said he would leave the matter in the hands of the subscribers present, but it would mean a close run on their funds.

The resolution was unanimously carried, and thus the Fund starts the year with a clean election sheet. A cordial vote of thanks to the Chairman closed the proceedings.

The Friendly Supper.

The Committee and a few friends assembled at 6.30 p.m. for the annual friendly supper, Mr. Henry B. May, Chairman of Committee, presiding. The attendance was less than usual, owing to several members of the Committee being confined to their homes with influenza.

THE HORTICULTURAL CLUB.

FEBRUARY 11.—At the annual general meeting of this club, held at the Hotel Windsor on the above date, a satisfactory report was laid before the members. It showed that the membership was well sustained and the financial position good, though the club had to deplore the deaths of several members, including Dr. Masters, Mr. James Veitch, and Mr. Assbee. During the season a number of interesting and instructive lectures had been given after the monthly dinners.

Among the new members were Dr. Farmer and Sir Frank Crisp, the latter of whom had accepted the vice-presidency of the club. It was decided to invite Dr. Farmer also to become a vice-president. Sir John T. D. Llewellyn, Bart., was unhappily prevented by indisposition from being present either at the meeting or the subsequent dinner, at which Mr. Harry J. Veitch presided. Some 80 members and guests attended this function, including a good number of ladies, and the toasts were alternated with instrumental, vocal, and humorous interludes of high merit, while the tables were beautifully decorated with flowers, thanks to the generosity of Messrs. Jas. Veitch and Sons.

After the usual loyal toasts, Mr. Harry J. Veitch proposed that of the Horticultural Club, alluding to its association with the Royal Horticultural Society and to the aid rendered to that society at a critical period of depression, now so happily replaced by success such as had that day been recorded in the neighbouring hall. Dr. J. B. Farmer responded, and especially emphasised the value of the club, not merely as a social centre of horticulture, but as constituting a material adjunct to the greater society by its lectures, papers, and discussions, which did so much to bring together for mutual and general benefit the scientist and the practical grower, the one seeking the causes of natural phenomena, the other by exhibiting the results. The toast of the Royal Horticultural Society was given by the Rev. J. H. Pemberton, and responded to in a very humorous and piquant speech by Sir Albert Rollit.

Sir Frank Crisp proposed the health of the Chairman, Mr. Harry J. Veitch, and, in replying, Mr. Veitch proposed that of the Honorary Secretary of the club, Mr. E. T. Cook, to whom its success was so largely due by his efforts to obtain interesting lectures.

Mr. W. A. Bilney proposed the toast of the Visitors, to which Mr. P. Anderson Graham responded, and also Colonel Lewis, a visitor from the Cape, who gave an insight into our relations with the Colonies generally, and with South Africa in particular.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

FEBRUARY 6.—*Committee present:* Messrs. E. Ashworth (chairman), R. Ashworth, Cypher, Ball, Sander, Upjohn, Shill, Ashton, Ward, Warburton, Cowan, P. Smith, and Weathers (hon. sec.).

There was a slight falling off in the number of groups shown at this meeting, and it was noticeable that the number of Cypripediums especially was smaller. The competition in Sander's Cup for Cypripediums was well maintained, and exhibitors are keen for the possession of this valuable prize.

A. WARBURTON, Esq., Haslingden (gr. Mr. Dalgleish), staged a group of Cypripediums, to which a Silver Medal was awarded. In the group were C. × Archimedes, var. nigrum, C. × Marguerite, and C. × Fowlerianum, Vine House var., to all of which Awards of Merit were granted. Other plants worthy of note were C. × Traceyanum, and C. × Exul-Sanderæ.

G. SHORLAND BALL, Esq., Burton, Westmorland (gr. Mr. Herd), received a Silver Medal in the Sander Cup competition for a group of Cypripediums. The group was not large, but there were several interesting plants, including Cypripedium × Spiceroni, a hybrid between C. Spicerianum and C. × Thompsoni, both of which received Awards of Merit. C. × Veronicus, C. × Miss Louise Fowler, Ball's var., C. × Alcibiades, Ball's var., and C. × Sallie (the latter a cross between C. × Sallieri and C. × Leeanum virginale) were also granted Awards of Merit.

E. ROGERSON, Esq., Didsbury (gr. Mr. Price), staged a small group, to which a Bronze Medal was awarded. Cypripedium × Brilliant, Oakdene var., received an Award of Merit. Other notable plants in this group were Cypripedium × aurem var. Surprise, C. × Zeus, Oakdene var., and C. villosum var. "Prince Noir."

Mr. A. J. KEELING received a vote of thanks for a small group, in which was shown Bulbophyllum comosum.

J. MACARTNEY, Esq., Bolton (gr. Mr. Holmes), staged a miscellaneous collection of plants in which was a small group of Cattleyas and Lælias, in addition to a collection of Cypripediums. (Silver Medal.)

DREWETT O. DREWETT, Esq., Riding, Mill-on-Tyne, exhibited an interesting display of Cypripediums, several good forms of C. insigne being prominent. C. insigne "Grand Monarch," C. i. Procysn, and C. × Leeanum var. Purity received Awards of Merit.

H. J. BROMILOW, Esq., Rainhill (gr. Mr. Morgan), sent a magnificent display of Cypripediums, to which a Silver-Gilt Medal was awarded. In this group the following plants received Awards of Merit, viz., C. × Hera, Rann Lea var., C. × Greenbank, and C. × Greenbank var. rubens.

S. GRATRIX, Esq., Whalley Range (gr. Mr. Shill), received an Award of Merit for Cypripedium × Stepmanii.

Messrs. CYPHER & SONS, Cheltenham, had a good display of miscellaneous plants, Cypripediums, Cattleyas, &c., to which a Silver Medal was awarded.

Messrs. MOORE & Co., Rawdon, near Leeds, displayed a small group, in which was a plant of Dendrobium speciosum and a well-flowered plant of Lycaste plana var. Measuresiana, the latter receiving a Cultural Certificate.

Messrs. H. LOW & Co. were awarded a Bronze Medal for a small but very effective group of Cypripediums.

Messrs. SANDER & SONS, St. Albans, staged three good Odontoglossums, including one hybrid and two fine forms of O. crispum.

J. H. CRAVEN, Esq., Keighley (gr. Mr. Corney), received an Award of Merit for Cypripedium × Eury-nitens, the parentage being C. × Euryades and C. × nitens. *P. W.*

LINNEAN SOCIETY.

FEBRUARY 6.—At a meeting held on this date, Mr. Horace W. Monckton, Treasurer and Vice-President, exhibited specimens and lantern-slides of leaf-impressions from the Reading Beds, on behalf of himself and Mr. O. A. Shrubsole, F.G.S., who was prevented by illness from being present.

The first paper was by Mr. Clement Reid, F.R.S., F.L.S., on "Fruits and Seeds from the pre-Glacial Beds of Britain and the Netherlands," especially on the Pakefield specimens from the neighbourhood of Lowestoft (Cromer Forest-Bed), and from Tegelen, near Venloo, in the province of Limburg, Netherlands. The substance of his observations has been published in the *Verhandelingen* of the Amsterdam Academy and *Linnean Journal*, Botany, Vol. xxxviii. (1908), pp. 206-227. One special point was his discovery of a species of Euryale, which he had named E. europæa; in this name he had been forestalled by Dr. C. A. Weber, whose plant, though congeneric, was a different species, and came from the neighbourhood of Moscow. As therefore his own species had to receive another name, he proposed calling it after the locality in which it was found, E. burgensis.

A paper by Mr. S. T. Dunn, F.L.S., on "A Botanical Expedition to Central Fokien," was briefly laid before the meeting by the General Secretary. The author stated that in April, May, and June, 1905, a botanical expedition was undertaken, with three native collectors and one Chinese herbarium assistant, to the centre of the province of Fokien. The difficult journey from Foochow to Yenping was successfully accomplished, and enough stores deposited at that town to enable a large collection of plants to be made. The central portion of this province, which is as large as England and Wales combined, had never previously been visited by a botanist, and, as might be expected, a considerable number of novelties were discovered, and are here described, amounting to at least 40 new species.

BRITISH GARDENERS' ASSOCIATION.

FEBRUARY 11.—The last meeting of the Executive Council of this association was held at the Royal Horticultural Society's Hall, Westminster, on the above date, Mr. Chas. Foster in the chair. Twenty-four new members were elected, bringing the total up to 1,163. The Secretary submitted a detailed statement, estimating the receipts and expenses of a monthly *Journal*. The question was thoroughly discussed, and it was decided by eight votes to three that a monthly *Journal* should be established in April, after the next issue of the present quarterly one. A request to hold a meeting for the benefit of the gardeners employed in the London parks having been received, it was decided that one would be held at Carr's Restaurant on Saturday March 7, at 7 p.m., and the secretary was deputed to give an address on that occasion. It was also decided to send a delegate to address a meeting at the Wesleyan School, Evelyn Road, Richmond, Surrey, on Tuesday, February 25th, at 8 p.m., when Mr. Hawes will be in the chair. The secretary was instructed to procure a die for the new certificate. *J. W.*

NATIONAL CHRYSANTHEMUM.

FEBRUARY 17.—A meeting of the Executive Committee of this Society was held at Carr's Restaurant, Strand, on the above date, Mr. Thomas Bevan presiding. The chairman extended a cordial welcome to the newly-elected president, Sir Albert Rollit, who was present. Sir Albert, in reply, returned thanks for his election, and advanced several ideas for the increasing of the membership. A letter from Mr. C. E. Shea was read accepting his election as a vice-president, and also a letter from the Crystal Palace Co., confirming the dates of the shows and the conditions of the agreement between them and the Society. Two societies were admitted in affiliation.

One-third of the Floral Committee retiring by rotation, the following members were elected:—Messrs. Curtis, Higgs, Oliver, Prickett, Springthorpe, Felton, and Newton. The members of the Finance and other Committees were also elected. The prospective budget of the Society for the year was next submitted. The date of the annual outing was fixed for July 27.

The secretary stated that he had received a notification of flower shows to be held during the Franco-British Exhibition, at Shepherd's Bush. Mr. Harman Payne enquired if any provision had been made for a Chrysanthemum show towards the close of this exhibition, as there were sure to be enquiries from some of the foreign members of the N.C.S. The secretary promised to enquire and reply later.

DEBATING SOCIETIES.

BATH AND DISTRICT GARDENERS'.—The usual fortnightly meeting of this society was held on February 10, Mr. T. Parrott presiding. There were the customary exhibits of fruit, flowers, and vegetables. Three new members were elected. The subject of the annual outing was discussed. The hon. secretary (Mr. F. L. Ashman) stated that the committee hoped to arrange a visit to Cardiff Castle. On the proposition of Mr. F. W. Hooper it was unanimously agreed that, if it be possible, the outing should be held on the same day as the Cardiff flower show. The remainder of the evening was devoted to open discussion.

SALISBURY AND DISTRICT GARDENERS'.—At the meeting of this society held on the 12th inst., Mr. W. Palmer, Andover, read a paper on the "Primula." A large number of the members were present. The lecturer dealt especially with P. sinensis, giving full particulars of its cultural requirements. Many members were of the opinion that the "stellata" type was the most desirable and useful. Many questions were asked and satisfactorily answered. Besides a group of well-flowered plants of Primula sinensis staged by the lecturer, Messrs. Keynes, Williams and Co. had an attractive exhibit. Much interest was caused by some well-flowered plants of Primula × Kewensis staged by Mr. S. W. Tucker, Longford Castle Gardens.

GUILDFORD AND DISTRICT GARDENERS'.—The usual fortnightly meeting of this association was held on Tuesday, February 4, Mr. W. Hogsden presiding over an attendance of 50 members. Mr. W. F. Binfield delivered a lecture on the "Greenhouse Cyclamen," giving his method of seed sowing and the subsequent cultural treatment of the plants to the flowering stage. The most suitable compost in which to grow the plants, potting, watering, syringing, temperature, the use of chemical and organic manures, insect pests and their extermination, &c., were touched upon, and important details ably explained by the lecturer. The discussion which followed proved interesting and profitable. *J. G.*

BRISTOL AND DISTRICT GARDENERS'.—A meeting of this association was held on Thursday, February 13, at St. John's Parish Rooms. Mr. J. C. House presided over a good attendance of the members. Mr. Baily, a representative of the Reading society, read a paper on "Budding and Grafting." The lecturer afterwards gave a practical demonstration of his subject, interspersing brief explanatory remarks while he was operating. Mr. Baily was freely questioned, the answers to which were as instructive as the lecture. *H. W.*

WARGRAVE GARDENERS'.—At the last ordinary meeting of this association Mr. G. Stanton read a paper on "The Beauty of a Garden in Winter." Besides giving a description of the many trees, shrubs, and plants useful to furnish a cheering aspect at the dull period of the year many other points were considered, such as the shape, colour, and covering of leaf buds, the bark of trees, the effect of raindrops and frost on the leaves and branches, &c. A discussion followed the reading of the paper.

CHESTER PAXTON.—The third lecture for the winter session was delivered at the Grosvenor Museum, on Saturday, by Mr. Jos. Thompson, on the "Flora of India and Ceylon," his remarks being based upon personal recollections of his Indian travels. With the aid of a series of lantern slides the lecturer gave a clear description of the principal trees, plants, vegetation, and fruits of India. Some specimens were also exhibited by Mr. Thompson. The beautiful scenery of the Island of Ceylon was shown by a set of coloured slides, among which were some delineating the growth, gathering, and drying of the leaves of the Tea plant. The general Flora of this island was also well described.

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending February 15, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The *weather* was again finer and drier in the eastern and southern districts than in the west and north-west, but nowhere was it very bright, and a considerable amount of fog or mist was experienced during the earlier half of the period over England. Thunder occurred in the Hebrides on Thursday.

The *temperature* was above the average, the excess amounting to more than 3° in most parts of England and Ireland, and to nearly 5° in Scotland. The highest of the maxima were registered on rather irregular dates, and ranged from 55° in Scotland E. and Ireland S., and 54° in some English localities, to 50° in Ireland N. The lowest of the minima, which were recorded during the latter half of the week, were below 32° in all the English and Scottish districts, and as low as 22° in England S. and 21° in the Midland Counties. In Ireland, however, the thermometer fell no lower than 36°. On the grass there were minima of 17° at Greenwich, 18° at Llangammarch Wells, 19° at Kew, Cambridge, and Tunbridge Wells, 20° at Crathes, and between 20° and 25° in many other localities.

The *mean temperature of the sea* was again higher than the corresponding week of last year, the greatest excess being 4° at Fennan Bay. The values ranged from about 47° at Newquay and Seafield to about 39° at Margate and the Shipwash Lightship.

The *rainfall* was considerably less than the normal in all districts excepting Scotland N., where the deficiency was slight, and in England N.W., where there was a trifling excess.

The *bright sunshine* just equalled the average in Scotland E. and England S. and slightly exceeded it in the English Channel; elsewhere it was deficient. The percentage of the possible duration ranged from 35 in the English Channel, 29 in Scotland E., and 27 in England S. to 17 in Ireland N. and England N.W., and to 14 in the Midland Counties.

THE WEATHER IN WEST HERTS.

Week ending February 19.

Another warm week. During the past fortnight there has not been a single unseasonably cold day, and only one cold night—when the exposed thermometer registered 15° of frost. On the warmest day of that period, the 17th, which was also the warmest day of the year as yet, the temperature in the thermometer screen rose to 54°, which is about 10° higher than the average maximum reading for the middle of February. The ground still remains warm, and is at the present time about 2° warmer at 2 feet deep, and about 3° warmer at 1 foot deep, than is seasonable. Rain fell on four days during the week, to the total depth of rather more than half an inch, but previous to the 15th no rain worth mentioning had fallen for over five weeks. My soil gauges, through which no measurable percolation had passed for nearly a month, were re-started by the recent falls of rain, since which nearly three gallons has come through the bare soil gauge, but less than one gallon through that on which short grass is growing. The sun shone on an average for 2¼ hours a day, or half an hour a day longer than is usual at this period of the year. The first two days of the week were calm, but since then the wind has remained high, and in the windiest hour the mean velocity reached 18 miles—direction W.N.W. The average amount of moisture in the air at 3 o'clock in the afternoon fell short of a seasonable quantity for that hour by two per cent. The Double Snowdrop came first into flower in my garden in the spot selected for its observation on the 18th, or 10 days later than its average date in the previous 21 years, and precisely the same date as last year. *J. M., Berkhamsted, February 19, 1908.*

SCHEDULE RECEIVED.

Abbey Park, Leicester.—The annual show in the Abbey Park, Leicester, will be held on August 4 and 5.

MARKETS.

COVENT GARDEN, February 19.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

Watercress, per doz. bunches	0 4	0 6

REMARKS.—The supplies of English Grapes continue to be short, but bunches are arriving from the Cape. There is a good demand for Oregon and Californian Newtown Pippins, as the quality of these Apples is now very fine. Cape Fruit is arriving in increased quantities, but prices are practically the same as those of last week. Supplies of Apricots from Cape Colony are now finished. Teneriffe Tomatos are dearer. New Turnips and Carrots from France are now obtainable. Well-coloured Bananas are selling freely. English Mushrooms are cheaper. Trade generally shows a decided improvement. *P. L., Covent Garden, Wednesday, February 19, 1908.*

Potatos.

Kents: Up-to-Dates, 100s. to 105s. per ton; British Queens, 95s. to 100s. per ton; Scottish Triumphs, 95s. to 100s. per ton. **Lincolns:** Up-to-Dates, 100s. to 110s. per ton; Up-to-Dates (Blackland), 85s. to 90s. per ton; British Queens, 90s. to 105s. per ton; British Queens (Blackland), 80s. to 90s. per ton; Maincrops 100s. to 110s. per ton; Sir Jno. Llewelyn, 90s. to 100s. per ton; Sir Jno. Llewelyn (Blackland), 80s. to 85s. per ton; Royal Kidneys, 90s. to 95s. per ton; Royal Kidneys (Blackland), 80s. to 85s. per ton; Evergoods, 90s. to 95s. per ton; Evergoods (Blackland), 75s. to 85s. per ton; **Dunbars:** Up-to-Dates (red soil), 110s. to 115s. per ton; Maincrops (red soil), 120s. to 125s. per ton. **Scotch:** Up-to-Dates (grey soil), 90s. to 100s. per ton; Maincrops (grey soil), 100s. to 105s. per ton. **German:** Up-to-Dates, 4s. 3d. to 4s. 6d. per bag; Magnums, 4s. to 4s. 3d. per bag; Imperators, 3s. 9d. to 4s. per bag. **Belgium:** Kidneys, 3s. 9d. to 4s. per bag. **Dutch:** Up-to-Dates 4s. to 4s. 3d. per bag; Magnums, 3s. 9d. to 4s. per bag; Imperators, 3s. 3d. to 3s. 6d. per bag. Trade is very quiet, and there are heavy stocks in London; consequently prices are low. *E. J. Newborn, Covent Garden and St. Pancras, February 19, 1908.*

COVENT GARDEN FLOWER MARKET.

Although the weather has been more favourable during the past week, there does not appear to be much improvement in trade. This may be partly accounted for by much produce being supplied direct from the growers to the retailers, and this causes many complaints in the market. Many plant stands are empty, but cut flowers are most abundant.

POT-PLANTS.

There is not a great variety in really good flowering plants. Indian Azaleas are the most prominent. These plants are remarkably good, but the growers must be experiencing a considerable loss, for the demand is poor. One salesman informed me that he had never known such a bad season for trade as the present. Some well-flowered plants of Azalea mollis are now seen. Erica Wilmoreana is remarkably well flowered this season. I noticed good plants of this Heath on Mr. P. Ladd's and also on Mr. Sweet's stands. The latter grower has also E. persoluta alba in well-flowered plants: the variety ovata is of very good habit, but it is not of the best colour. Cyclamen seen are well-flowered, and there are some fairly good Chinese Primulas. Begonia Gloire de Lorraine is not over plentiful, and good Liliums in pots are rather scarce. Marguerites are now very good, and sell fairly readily. Genistas are now well-flowered. Daffodils are abundant, the varieties seen in pots being Golden Spur, Princeps, and the double Van Sion. Hyacinths and Tulips are also plentiful. Spiræas from forced clumps are obtainable, but at present they are not so good as those grown from retarded stock. There is little variation in foliage plants. Solanums are not yet quite finished.

HARDY FLOWER ROOTS, &c.

There is seen quite a variety of hardy herbaceous plants and biennials: these include Carnations, Pinks, Hollyhocks, Campanula persicifolia (blue and white), Coreopsis, Lychnis, Herbaceous Phloxes, Herbaceous Cornflowers, Galegias, Herbaceous Pyrethrums, Sunflowers, Canterbury Bells, Irises, Wallflowers, Delphiniums, Aquilegias, Violas, Lavender, Rosemary, hardy climbers, Roses, fruit trees, hardy shrubs, Conifers, &c. Also Strawberry plants, Cabbage plants, Rhubarb roots, a variety of Herbs, &c.

CUT FLOWERS.

Tulips are still a leading feature among cut flowers: samples vary considerably in quality, and some senders may be disappointed with the returns made. It is difficult to sell best samples, and any of second quality can only be sold to street hawkers at very low prices. Many of the costers are particular as to quality, and will pay good prices for best samples. Daffodils from English growers are very abundant. Victoria and Horsfieldii are the best "bicolors." Emperor, Sir Watkin, Golden Spur, and Henry Irving are other leading sorts. Narcissus poeticus and several varieties of the polyantha type are plentiful. Large supplies are now coming from the Channel and Scilly Islands. Roses vary considerably in quality. I noted some very bright blooms of the variety Richmond this morning. A few Mrs. J. Laing are also coming in the market, but they are rather small. Nipthetos is very good. There are very few good blooms of Catherine Mermet seen, most of them being of a very pale colour. Carnations are seen in large quantities at this season of the year. It is difficult to quote prices, for after the ordinary buyers are supplied the remainder is sold very cheaply. Gardenias and Eucharis are scarce. Lily-of-the-Valley, Tuberoses, Camellias, double white Primula, and Callas are all plentiful. Liliums vary but little. Imported flowers include Roses, Violets, Anemones, Ranunculus (double crimson and yellow), Yellow Marguerites, Mimosa (Acacia), Callas, &c. *A. H., Covent Garden, February 19, 1908.*

GARDENING APPOINTMENTS.

[*Correspondents are requested to* ***write the names of persons and places as legibly as possible.*** *No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting Box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.*]

Mr. J. C. LUNNON, for the past 2 years Gardener to Mr. A. P. HILLIER, Markyatebell, Dunstable, as Gardener to Mr. BECK, Harrold Hall, Bedford

Mr. JOHN MACGREGOR, lately Gardener to R. H. ELLIOT, Esq., Clifton Park, Kelso, N.B., as Gardener to WM. YOUNGER, Esq., Achen Court, Moffat, N.B.

Mr. GEO. KEW, late Gardener to Lord BRADFORD and for three months traveller to Messrs. RICHARD SMITH & Co., Worcester, as Gardener and Bailiff to EDWIN GREEY, Esq, Brookencote Hall, Chaddesley Corbett.

Mr. J. HAMMOND, late Gardener at Norton Curbeu, Warwick, and Ardencote Claverdon, as Gardener to G. P. FITZGERALD, Esq., The Island, Waterford, Ireland.

Mr. FRANK HURFORD, as Gardener to A. BOULDERSON, Esq., Beeston Hall, Neatishead, nr. Norwich.

Mr. WM. SIMPSON, late of Wemyss Castle Gardens, and previously at The Grange, Sutton, Surrey, has been appointed Steward and Gardener to R. C. FORSTER, Esq., at the latter place.

Mr FRED CLARK, previously Gardener to Lord BATEMAN, Shobdon Court, Shobdon, Herefordshire, as Gardener to A. E. WRIGLEY, Esq., Street Court, Kingsland, Herefordshire.

Mr. F. SOMERFORD, late Foreman at Gordhinog Gardens, Llanfairfechan, North Wales, and previously at Ingestre, Wentworth, &c., as Gardener to ALBERT WOOD, Esq., Bodlondeb, Conway.

Mr. J. T. HAYES, of Burbage, Hinckley, has been appointed, from amongst 217 applicants, to the post of Superintendent of Parks and Gardens to the Borough of Royal Leamington Spa.

ENQUIRY.

SEA SAND FOR BOWLING GREENS.—Can any reader give me his experience with sea sand for bowling greens or lawns? I have had this winter to strip a bowling green in order to level it, that has been treated for two years with tons of sea sand, and I have never seen such bad turf before. The colour of the grass is quite yellow. *W. Davis.*

Answers to Correspondents.

ADDRESS: *F. G. L.* The Prianlx Patent Trough Co., Ltd., St. Martin's, Guernsey.

BOOKS: *B. O. S. The English Flower Garden*, by W. Robinson, price 15s. 6d., or *The Flower Garden*, by T. W. Sanders, price 8s., would be suitable for your purpose. Both these works can be obtained from our publishing department. We believe Messrs. H Cannell and Sons, Nurserymen, Swanley, publish a work on designs for carpet bedding. *Mrs. B. British Fungi* or *British Edible Fungi*, both of which works are by Dr. M. C. Cooke, will be found suitable for your purpose. Thanks for your contribution to the R.G.O.F. box.

CALANTHE GROWTHS SPOTTED: *A. E. G.* The dark-brown spotting on the skin of the pseudo-bulb of Calanthe Veitchii is not an uncommon occurrence, and especially in the case of plants grown in the same garden and from the same stock for many years. The damage is often confined to the thin, silvery covering of the pseudo-bulb, and the new growths are quite healthy until the resting season arrives. In cases where the damage extends to the tissues of the pseudo-bulbs it is better to destroy all plants so affected, and to increase the stock from those only superficially harmed. It would be well to renew the stock by procuring perfectly healthy plants from some other garden.

DESTROYING MOLES: *F. B.* It is usually more difficult to trap moles at this season than at any other time of the year, and considering the creature's feeding habits it is almost impossible to administer poison. Fine meshed wire netting buried vertically to a depth of 18 inches or thereabouts would probably prevent them from burrowing, but the top of the netting must be above the surface of the ground, for moles often travel far distances above ground. To enclose a garden of considerable size with wire netting is a costly proceeding. Small lengths of barbed wire or pieces of bramble pushed into the burrows will often drive moles away from a locality. But, on the whole, when trapping fails, the most effective method is to soak small pieces of sponge or strips of any woollen material in petroleum and to push the soaked strips into the runs as near as possible where the moles first enter the garden. The cheaper and more noxious smelling the oil the better; that usually sold as paraffin oil is more effective than the refined brands. So long as the smell remains no mole will come near it. As long as the moles infest the neighbourhood fresh paraffin oil must be placed in the runs about every fortnight—oftener, should the weather be very wet Failure to trap moles is often due to carelessness in setting the traps. It is essential that every ray of light be excluded, or the mole will avoid the trap—usually by burrowing underneath it. Where the nature of the ground does not easily permit the trap to be darkened, an old wet sack should be laid over it. When setting traps care should be taken to disturb the runs as little as possible, and any soil which falls into the run should be carefully removed. These sagacious little creatures have a keen sense of smell, and are naturally suspicious of any unusual occurrence. Experienced trappers deliberately smother their hands with damp soil before placing the traps in position.

FEEDING BEES: *R. O. P.* If the bees have sufficient food they are best left alone, but if they are short then place the frame of honey under the quilts on a fine day. Replace the coverings as quickly as possible in order to prevent the heat from escaping, and afterwards fill up the corners with some soft material so that the heat may not escape through the gaping corners.

GRUBS ATTACKING CARROTS: *F. A. Edwards.* The grubs are those of a small fly, but they are, however, certainly not the grubs of the "Carrot fly" (Psila rosæ). Many of the grubs of flies feed on decaying vegetable matter or manure, so that if the soil has been recently dressed it is quite possible that they may have been imported in the dressing, and will not injure a future crop. If no dressing has been applied, they have probably been feeding on the roots of some other plant or plants. A little gas lime, or vaporite, applied to the land will no doubt kill them.

GRUBS IN SOIL: *A. L.* The pests attacking the roots of your Adiantum Ferns are weevils. Trap them with pieces of some vegetable such as Potato or Carrot, and hunt them at night, at which time they feed.

HARDY AZALEAS INFESTED WITH LICHEN: *R. H. E.* Spray the plants with the solution at half strength when the buds are quite dormant

INSECTS FROM A PIGEON LOFT: *T. S.* The insects which you send are meal worms, the grubs of a beetle belonging to the genus Tenebrio. They are not injurious to plants in any way, so you may safely use the manure as far as they are concerned. These grubs very much resemble wireworms, but they belong to a very different family. They are generally found in flour, meal, bran, or some other farinaceous matter.

INVENTION: *W. S.* Apply to the Registrar, Patent Office, 25, Southampton Buildings, London, W.C.

NAMES OF PLANTS: *D. P.* 1, Abies magnifica; 2, Cupressus Lawsoniana; 3, Thuya occidentalis; 4, Cupressus pisifera; 5, Cupressus Lawsoniana aureo-variegata; 6, Cupressus nootkatensis var. —*Veritas.* 1, Odontoglossum cordatum; 2, Oncidium crispum; 3, Aerides falcatum; 4, Brassia verrucosa —*W. B.* The Calanthe appears to be Calanthe Veitchii The labellum has withered, and the chief feature is thus destroyed. The Odontoglossum is O. Pescatorei. The species usually has some rose markings on the lip, but varieties such as you send are not uncommon.

NAMES OF FRUITS: *F. L.* 1, Harvey's Wiltshire Defiance; 2, Bergamot d'Esperen; 3, Dr. Harvey.—*J. Taylor.* Tyler's Kernel.

ODONTOGLOSSUMS: *W. B.* In reply to your questions:—(1) It would be better to establish the imported Odontoglossums before dividing the pseudo-bulbs. (2) The use of comparatively small pots is best in the case of imported plants, and relatively larger ones when the plants are rooting freely. (3) The growth of the pseudo-bulbs is arrested by the production of flower-spikes in the stage you describe. If flowering is likely to injure the plant, remove the flower-spike. (4) You should re-pot any plants which are in too small pots at once. (5) Pot the plants of O. Pescatorei, which are in crocks, and which are now sending out roots. (6) The question of "feeding" Orchids is a much-debated one. The best growers maintain that they give nothing but pure rain water. For some strong-growing species weak liquid manure made from dried cow-dung is advocated by many gardeners.

OVERHANGING TREES: *F. D.* You are entitled to remove any of the branches from your neighbour's trees that overhang your property, but you must be careful not to go beyond the limit of your fence.

PLANTAINS IN GRASS: *G. W. C.* As the area is too great for eradicating the weeds by hand, the grass should be given a dressing of some nitrogenous manure. This will encourage the growth of the grasses, and these will in time crowd out the weeds. A pinch of salt or of sulphate of ammonia dropped in the crown of each Plantain will kill these weeds, and piercing them with a skewer that has been dipped in some strong acid will also prove efficacious in their destruction.

PLUMS AND RASPBERRIES FOR MARKET: *Machany.* The variety of Raspberry most largely grown in the southern counties and the Midlands is Superlative, and it is also being planted extensively in the north. Superlative is an excellent variety, for it has a good constitution, is prolific, and produces fine fruits. Carter's Prolific is also extensively grown, together with Norwich Wonder and Baumforth's Seedling. Hornet is a favourite variety with some planters on a large scale, the fruits being excellent for preserving purposes. In the Scottish Raspberry fields in Blairgowrie are planted Clyde-Side, Red Antwerp, and Maclaren's Prolific in great quantities. The results there have been astonishing, as from 3 to 4 tons of fruit per acre is a common crop, while as much as 6 tons has been recorded in some seasons. The first-named of these varieties is now not much grown in the south, and the other is seldom seen. Of Plums, Rivers' Early Prolific, Czar, Victoria, and Monarch are useful if the position and soil are adapted to them, but you must be careful to ascertain these particulars first. A convenient method of planting these fruit trees is to place the Raspberries 3 feet apart in rows 6 feet asunder, and the Plums (standards) at 18 feet each way, in the lines. By this means 106 Plum trees and about 2,000 Raspberry stools will occupy each acre of ground. Healthy trees and strong sets of Raspberries sufficient for planting an acre would cost from £18 to £25. The expense of cultivation and planting will depend upon the condition and nature of the land, also whether horse labour can be employed in the former work or not. If ploughing, cultivating, and harrowing will suffice as a preparation, from £3 to £5 per acre will be needed as a total outlay on the whole work. If digging or forking by hand labour is requisite, or if the land is very foul, double these amounts will be necessary. Thorough cleaning of the ground is essential as a preparation for Raspberries, and liberal manuring also if the land is not naturally fertile. Artificial manures would cost from £2 to £3 per acre, but if stable or farmyard manure is used the expense would be much greater according to the distance from a source of supply.

ORSETT HALL, GRAYS.

CHARMINGLY situated in a fertile and pretty part of Essex, within three miles of Stanford-le-Hope and four miles of Grays, on the London, Tilbury and Southend Railway, is Orsett Hall (fig. 50), the picturesque residence of Francis H. D. C. Whitmore, Esq., J.P. The Orsett estate is extensive and well maintained, as a three-mile drive through a portion of it shows readily.

The Hall is a very old, timber-built edifice, encased in brick, and has been altered from time to time by its owners, including the present one, who has made extensive additions and alterations since he succeeded to the property. It contains valuable ceilings and fireplaces of the Tudor period. D. W. Coller, in his book (1861), says: "The Hall, or the White House, as it is sometimes written in old documents, was formerly a huge, timber-built erection, much of which was pulled down in the last century, and the remainder has been so encroached upon and changed by the modern architect, that little of its ancient character can now be traced. It has lately been considerably enlarged, and the grounds have also been rearranged by Mr. Marnock, of London." These remarks apply to the Hall as it was 46 years ago. The walls of the south front are, with the exception of a few plants of choice climbing Roses planted on either side the entrance door, clothed nearly to the top with the rambling shoots and pretty foliage of the Virginian Creeper (Ampelopsis hederacea). The portion of the front of the building shown bare in the picture above the Ampelopsis line consists of slate secured to the external framework of the building, and, therefore, on account of its hard, smooth surface, offers no opportunity for the Ampelopsis to extend beyond the topmost course of bricks, the tendrils being unable to attach themselves to the slates. The walls at the west end of the mansion are well furnished with fine plants of Wistaria sinensis. In the summer season, beds in close proximity to the Hall are filled with a variety of flowering plants, which contrast effectively with the closely-cut green lawn and choice trees and shrubs. A border runs at the base of and parallel with the terrace wall (upon which are stood some vases well filled with flowering plants at short intervals), and this at the time of my visit last season contained at the back a row of grandly flowered plants of White Marguerites, next a row of well-flowered plants of Henri Jacoby Pelargonium, with its large trusses of dark crimson flowers, and an edging of dwarf-growing variegated-leaved Pelargoniums.

FIG. 50.—ORSETT HALL, GRAYS, THE RESIDENCE OF FRANCIS H. D. C. WHITMORE, ESQ.

In the grounds were observed many grand specimens of choice trees, some of them the finest the writer of this note had hitherto seen in this country. In the west garden stands a fine specimen of Sequoia gigantea, about 70 feet high, with a girth of trunk of about 4½ feet a couple of feet from the ground. This tree—one of several others of the same kind—is perfectly straight and vigorous in growth, the branches brushing the ground. A truly magnificent tree of Ginkgo biloba (Salisburia adiantifolia) measures about 50 feet in height, and has a circumference of trunk of 8 feet at 4 feet from the ground. A Cedar of Lebanon (Cedrus Libani) on the south lawn is a noble specimen; this tree has a girth of trunk of 23 feet at 4 feet from the ground, and an immense spread of healthy branches brushing the green sward, the tree being in a vigorous state of health, there being no evidence whatever of declining vitality, as is too often met with in trees of this kind of large dimensions. A healthy specimen of Araucaria imbricata (see fig. 51), about 50 feet in height, furnished with branches all around from the ground upwards, has a girth of trunk of 6 feet at 4 feet from its base. Grand specimens of Taxodium sempervirens, measuring about 70 feet in height and furnished from the base upwards with healthy, well-developed growth; equally large trees of Thuja gigantea and Cupressus nootkatensis were observed at the west front of the house. An example of the Mop-headed Acacia, with a clear stem for a height of 6 feet, had a spread of branches about 20 feet through, or 60 feet in circumference. This tree on the occasion of my visit afforded agreeable shade from the sun's rays. A pleasant part of the grounds is that in the south garden, known as the Dell, in which many choice tropical subjects luxuriate under the protecting shelter afforded by larger and commoner kinds of trees and shrubs. These include, among others, plants of Chamærops humilis, Aralias, Cordyline australis, Mimosa, Bignonias, Bambusa, Eucalyptus, and Camellias, which remain in robust health all the year round out of doors. Paulownia imperialis also succeeds well at Orsett. Looking east, on the right-hand side of "Church Walk," some new beds, rendered beautiful by a judicious arrangement of bedding plants, were observed, as also was a bed planted with Rhododendrons at the end of the terrace wall. A high Holly tree,

over which a plant of the Irish Ivy (Hedera hibernica) has gained the mastery, is not the least interesting feature in these very delightful and beautifully kept grounds, which, though not extensive, are by skilful arranging and planting made to appear of much larger area than they really are. There are no bare or unattractive spots to be seen in any part of the place. Variety and pleasant surprises in scenery meet one at almost every turning. It was noticed that a free and effective use had been made of Berberis aquifolium as a groundwork, not only alongside the principal avenue drive, but also in many places in the grounds, with pyramidally-trained specimens of Holly, Aucuba japonica in bush form, Cedrus Deodara, &c., showing well above the shiny foliage. Hedges of perennial Asters (Michaelmas Daisy) were observed in the vicinity of the kitchen gardens and alongside walks leading therefrom in other directions. Before taking leave of the grounds, mention may be made of several large bushes of Almond (Amygdalus communis) some 15 or more feet in diameter, and which, when in flower in spring time, must be beautiful objects.

In the kitchen garden good crops of vegetables were observed, as also were Pear and Apple trees bearing heavy crops of well-developed, clean fruits. The trees are planted in rows about 10 feet apart and at the same distance in the rows. A number of shoots have been allowed to grow upwards and outwards from each tree from the time they were planted nine or ten years ago, and these leading shoots or branches have been kept spurred close back each year at pruning time, thereby admitting plenty of light and air to the shoots. Amongst the varieties of Apples which attracted my attention were heavily cropped trees of Cox's Orange Pippin, Worcester Pearmain, Lady Sudeley, Annie Elizabeth, and Warner's King. The trees in the outside rows, both at the sides and ends, were more evenly and heavily cropped than were the inner trees. The soil at Orsett is a reddish loam.

A grand old Mulberry tree at the north front of, and close to, the Hall must not be overlooked in this notice. It has three or four main branches proceeding from the trunk at about 4 feet from the ground, these being supported by substantial props at 9 or 10 feet from their origin. The tree is in fine condition, notwithstanding its great age, and was at the time of my visit carrying the remaining part of a good crop of fruit. The tree is certainly the finest specimen of the kind with which I am acquainted.

In the fruit and plant houses were observed some well-formed bunches of Grapes. The Peach trees had just finished carrying fine crops of fruit. There was also observed a collection of stove and greenhouse plants of a decorative character. A promising lot of Chrysanthemums in pots, grown for the production of large blooms, were noticed. Mr. Neighbour, the head gardener, is to be congratulated upon the fine order in which the gardens and grounds are kept.

Mr. Whitmore, the owner, is a keen horticulturist, and is familiar with the names of all the trees, shrubs, and other plants growing on the place. He also possesses a good knowledge of their cultural requirements and of landscape gardening, as is proved by the many improvements that have been carried out in the grounds at Orsett under his personal supervision. *H. W. Ward, Rayleigh.*

THE FERNERY.

POLYPODIUM VULGARE VAR. CORNUBIENSE (SYN. ELEGANTISSIMUM).

As an example of polymorphic variation this Fern is probably unique. It was found growing wild in 1867 in Cornwall on a pollard Ash, and has maintained its peculiar characters ever since, whether propagated by division or by spores, although by persistent selection the tendency to reversion has been somewhat, though not entirely, suppressed in the case of P. v. C. trichomanoides. In this form of the Common Polypody three types of foliage appear, viz., the purely normal once divided or pinnate frond, a second in which the frond is divided and redivided into long, narrow lobes, consisting of little more than the midribs, and an intermediate, somewhat foliose form of the last-mentioned variety. The main peculiarity, however, of the variety under notice is the extremely erratic manner in which these three types assert themselves. Sometimes the plant consists of perfect fronds of the three types intermingled, or it may, as in trichomanoides, have its fronds as a rule of the finely-cut form, but occasionally a single frond or even a single pinna may present all three types. All these various fronds bear spores, but the most divided type has been observed, when grown under glass, to produce clusters of bulbils on the sites of the sori or spore heaps, and instances have been noted where, normal growth having been completed, the tips of the sub-divisions have lengthened considerably into linear extensions, indicating apparently apospory, although so far I have failed to induce this character by layering, and I have also failed to note any thinning of the cellular tissue, the usual preliminary to that phenomenon. The varietal instability which must underlie the polymorphic character is so truly transmitted when crosses are effected that the hybrid Polypodium Schneideri (P. vulgare cornubiense × aureum) is practically a gigantic P. v. elegantissimum, with all its faults; while a cross effected by Mr. Clapham with P. v. bifido multifidum eclipses even elegantissimum itself, since, besides the three types described, bearing crested or polydactylous tips, due to bifido-multifidum influence, the normal three types also persist in spots, so that no less than six variants occur on absolutely heterogenous lines. A complete frond of bifido multifidum, with its characteristic crest, may be next to a perfectly normal frond; while a finely-cut frond, with forked tips, having an insertion, so to speak, of a portion of bifido cristatum in one place, a patch of normal in another, and several divisions of the intermediate coarse type, may also be present on the same plant. There seems to be no rule in the matter of leaf division in this Fern; the young cells which start the formation of the divisions appear to be constantly changing, yielding first to one influence and again to another, but never producing foliage of any one constant type. Mr. H. B. May for several years had a plant of P. Schneideri, which bore large fronds of the P. vulgare form only, but of the size of P. aureum, and to which eventually a special name was given. Later on, however, this form proved inconstant, and again showed the variations of the older types. P. Schneideri being a hybrid between two quite distinct species, its spores are merely rudimentary; they appear plentifully, but are all imperfect. This is to be regretted, as otherwise it would afford a rare opportunity of studying a hybrid Fern on Mendelian lines. Incidentally in this connection I may mention that Bakerhead's Athyrium ff. Victoriæ × A. ff. setigerum, which unmistakably displays the two characters of tasselled cruciation and translucent bristly edges, yields exact replicas of the cross when its spores are sown, no segregation occurring at all. *Chas. T. Druery.*

FIG. 51.—ARAUCARIA IMBRICATA IN THE GROUNDS OF ORSETT HALL. (See p. 131).

PLANT BREEDING.

MANY growers do not pay sufficient attention to the proper selecting of their stock for seeding purposes. This is a matter that requires careful study. One of the most curious points that I have noted in cross breeding plants is, that while some hybrids will show little variation from their parents, seedlings raised from the seed of selected plants which have not been cross fertilised may occasionally vary considerably. Yet selection is, on the whole, more advantageous than indiscriminate crossing. I have examined whole beds of annuals, and marked one plant here and there from which the seed was specially saved for home sowing. The plants were grown extensively for sale, and only a few of the very best were selected and saved each year for producing seed. This is an advance on indiscriminate seed saving in the case of stocks grown entirely for seed, for all, except rogues or very poor examples, contribute to the seed-bag. Careful selection year by year, and the progeny of each individual plant kept separate, will prove which are the best for seeding purposes. This rigid selection will also keep up the strain to its highest standard, if it does not considerably improve it. If, however, seeds are not saved from carefully selected stock, the quality of the strain will deteriorate. Even in the case of many plants which are propagated annually from cuttings, it is an advantage to raise fresh seedlings at times and to select the best for stock. The yellow Carnations may be instanced in this connection; there are few varieties which last many years

when raised from cuttings, but carefully crossed seedlings will give new vigour and probably other improvements. The seed parent should be of vigorous habit, and that from which the pollen is taken should have flowers of the best shade of colour. This applies to all colours: the pollen parent will generally influence the colour. If intermediate colours are desired, two distinct shades may be inter-crossed, but, as a rule, it is better to select a good form of flower as the mother, and to use a similar or brighter shade for furnishing the pollen.

Pollen taken from another plant of the same variety is better than that taken from the same flower. Where it is desired to effect crosses, bees and other insects must be excluded. Another important matter is to remove all stamens from flowers before the anthers burst, and also all other flowers from the plants, except those that are intended to be fertilised. Another detail is to exercise care to take the pollen from flowers which have not been contaminated with that from others of inferior quality.

The best method of transmitting the pollen is by the aid of a small camel-hair brush, or in some instances the flowers themselves may be brought into juxtaposition. The proper time for pollinating is when the head of the pistil is moist. The stigmas of some flowers are receptive for days together, whilst other lose their potency quickly. A few seeds of carefully fertilised flowers may give better results than larger quantities which have been procured with less care. Indeed, one of the greatest mistakes is to harvest too much seed, for in that case some of the best seedlings may be thrown away through lack of room to accommodate the plants. *A. H.*

FIG. 52.—VANDA WATSONII AS CULTIVATED IN THE COLLECTION OF MAJOR HOLFORD.

VANDA WATSONII.

OUR illustration at figure 52 represents this pretty species as grown in the collection of Major G. L. Holford, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander). It was introduced by Messrs. Sander and Sons from Annam, where their collector, Mr. Schlitz, discovered it growing at an altitude of about 5,000 feet. The species was described by Mr. R. A. Rolfe in the *Gardeners' Chronicle*, February 11, 1905, p. 82, the name being given, at Messrs. Sanders' request, in compliment to Mr. W. Watson, curator of the Royal Botanic Gardens, Kew, who is not only a good orchidist, but enthusiastic in his appreciation for all well-cultivated plants. Vanda Watsonii resembles V. Kimballiana in habit, but its flowers are white and with fimbriated labellums. Both V. Kimballiana and V. Watsonii thrive admirably at Westonbirt, grown in shallow teak baskets, and suspended near the glass of the roof in an intermediate house. This section of the genus also includes V. Amesiana, which is of similar habit of growth, but with stouter stems and more fleshy leaves.

THE BULB GARDEN.

LEUCOJUM VERNUM VAR. VAGNERI.

THERE exists several well-marked varieties of the Spring Snowflake (Leucojum vernum), and references to these have appeared from time to time in the *Gardeners' Chronicle*. My attention was first drawn to them on reading, at the time of its appearance, a monograph of the Leucojums from the pen of the late Mr. William Brockbank, in the issue of March 15, 1884. The conclusions arrived at by Mr. Brockbank differ somewhat from those of Mr. J. G. Baker in his *Amaryllidae*, published four years later, and I have preferred to adopt the nomenclature of Mr. Baker. The name of Leucojum vernum var. Vagneri, however, does not appear in Mr. Brockbank's descriptions, and I cannot discover in his notes anything which would point to any knowledge of this variety, save, perhaps, a reference to a plant called L. v. carpathica by Mr. Niven.

This variety, however, is so valuable, either for planting in grassland or in the border, that it may well be brought to notice.

The variety which comes nearest to L. v. var. Vagneri in Mr. Brockbank's descriptions appears to be that called by him L. v. var. carpathicum, but this he describes as having yellow spots, whilst the one to which I refer as Vagneri has markings of a deep green colour, although the flowers are generally borne in pairs, like those of Mr. Brockbank's carpathicum. It is possible that the one spoken of by Mr. Niven, and simply referred to by Mr. Brockbank as "carpatica," may be the variety named Vagneri by Mr. Baker, and for which Mr. Stapf is the authority. In my opinion, it is the most valuable of all the Spring Snowflakes. It blooms about a month before the ordinary L. vernum or its yellow spotted variety, and it flowers quite as early as the common Snowdrop; indeed, in some seasons it appears before that early flower. It is occasionally catalogued under the name of carpathicum, and I have received both this and the yellow-spotted, one-flowered variety by that name from nurseries. It may be described as a tall, robust, early-flowering form of L. vernum with, as a rule, two flowers on a stem, though weak bulbs often produce but one, and as having larger bulbs and flowers, and with the green spots of a darker colour than the type.

GALANTHUS NIVALIS LUTESCENS.

The "yellow" Snowdrops form a small but beautiful class of these favourite early-blooming plants; the flowers, however, are not, as the name would suggest, entirely yellow, but the ovary and some inner markings, the leaves and flower stalks are also of a yellowish hue. So far as is known, they are varieties of the common Snowdrop (Galanthus nivalis), although

occasionally similarly coloured flowers appear among other species, but, so far as I have knowledge, these have not proved constant.

One of the prettiest of the small number in cultivation is the one named lutescens, which has the yellow colouring very marked, although not so bright as the larger flavescens, another of the same class.

G. n. lutescens is a small-growing and small-flowered variety, not considered robust or of good constitution in many places, but it has proved a good grower in my present garden. A few bulbs planted in a clump make a pretty feature in the rockery or in the grass, where the yellow colouring gives a touch of brightness not unwelcome in the early days of the year. This particular variety was found in an old garden in Northumberland, where it still exists in considerable quantity.

FIG. 53.—SPRAY OF FLOWERS OF VANDA WATSONII; FLOWERS WHITE.

THE PROPAGATOR.

FOR species of plants which need no special sorts of soil, it will be found that the refuse from the potting bench contains all the ingredients necessary for the germination of the seeds and the maintenance of healthy growth for a few weeks, that is, till such time as the seedlings are pricked out into pans, boxes, trays or pots. It is usually of a sandy nature, through which moisture percolates readily, and if it is not, it should be made porous by the addition of clean, sharp sand. This soil should be passed through a ½-inch sieve, and be put aside. The coarser particles can be used for filling the pots and seed-pans to half their depth, after sifting them through a ½-inch-meshed sieve to remove the too coarse lumps, and this, with one hollow crock over the hole at the bottom of the receptacle, will afford ample drainage, and yet not suffer the soil to become as quickly dry as would crocks or other hard materials that are non-absorbent. The fine soil can then be filled in to within ¼ inch of the rim, and pressed down evenly all over to that depth. When a number of the pots, &c., are thus treated, they should be set on a level floor and afforded as much water as will moisten the soil throughout, and be left till the next day.

Should potting-bench refuse be not available or be insufficient in quantity, good friable loam which has been stored for some months under cover may be used in place of it, taking the precaution to search for weevil grubs, crickets, and wireworms, all of which are voracious feeders on the tender roots of seedlings. With the loam, well-decayed leafmould may be mixed to the extent of a quarter of the whole, and in the case of strong growing plants a small quantity of thoroughly decayed stable manure may be used instead of, or in addition to, the leaf-mould. To this mass a goodly proportion of sand should be added, and the whole must be turned over twice or thrice, and passed through a ¼-inch meshed sieve, the coarser particles being used as above advised. Some species of plants thrive best in soil consisting wholly of soft peat, or of which the peat forms at the least one-half the bulk. Such plants are Gloxinias, Primula sinensis, Lisianthus Russellianus, Calceolaria herbacea, Rhodanthe Manglesii, &c. A dirty seed-pan or pot should never be used, nor are quite new ones desirable for seed-sowing purposes, unless they have been immersed in water for 24 hours. As seeds vary greatly in size, no strict rule can be laid down as to how deeply they should be buried under the surface; but it is safe to place the soil over them to the depth of their shorter diameter. Very small seeds should not be covered at all, but should be pressed into the soil with a smooth, circular bit of board, or the bottom of a flower-pot, and the soil may be moistened by immersing the seedpan nearly to the rim in a vessel of water. Seeds should never be sown so thickly as that when they germinate the plants crowd each other unduly and the roots become entangled.

One other matter to be thought of in time is the hot-bed or other pit, or garden frame, into which the seeds must be placed for germination. The most suitable is the pit filled with last autumn's tree leaves, or tree leaves and stable litter—not very much of the latter; and hot-water pipes or dung linings for affording top-heat. No seeds should be put into any such pit or frame till the bottom-heat has risen from 80° to 85°, and has begun to decline a degree or two. The heat will then, under a coating of half-decayed leaves, cocoanut fibre, or coal ashes, remain fairly steady at 75° to 80° for five or six weeks.

Seeds of the following species of plants may go into this pit or frame, wholly or half plunging the pots, or standing them on the bed, accordingly as they are natives of warm or temperate countries, viz., Calendulas, including the Marigold in variety, Balsams, Zea japonica (both green and variegated leaved), Amaranthus, Sweet Peas, Verbenas, Asters (annual species), Celosias, including plumosus and cristata, Grevillea robusta, Zinnias, Nicotiana Sanderi, Chinese Primulas, &c. Air must be afforded to strengthen the plants and get rid of the moisture arising from the bed, and on the least appearance of becoming drawn, the pot of seedlings should be placed into cooler quarters. The more hardy species should be allowed to germinate, and show their first pair of true leaves, and then without loss of time be placed in a house or pit close to the glass which is 10° cooler.

SEEDS OF STOVE PLANTS.

Seeds of Canna indica varieties, Thunbergia alata in its several varieties, Gloxinias, Gesneras, Streptocarpus hybrids, tuberous Begonias, and of many other inmates of the stove should be raised in a frame or pit having top-heat of 65° at night.

MISCELLANEOUS PLANTS.

Alternantheras in all varieties, Hoyas, Lasiandra macrantha, Hibiscus in variety, Iresine, Herbstii, I. Lindenii, I. Wallisii, Lantanas, Leucophyta Browni, Centropogon Lucianus, Eranthemums, Euphorbia jacquiniæflora, Francisceas and Tabernæmontana coronaria, may be raised from cuttings under similar conditions.

Under cooler conditions, Eupatorium odoratum, E. album, E. riparium, Tropæolum Lobbianum, and those with double flowers may be rooted from cuttings taken from plants that have begun to grow.

ROOT PROPAGATION.

This is an operation which can be carried out at this season with the following plants: Aralia japonica and A. spinosa, Gymnocladus canadensis, Ailanthus glandulosus, Sophora japonica, Weigela rosea, Morus, Rhus, Tecoma, and almost all plants with fleshy roots. The pieces of the root should measure from 2 to 3 inches in length, and be stuck upright in sandy soil in pots, so that the top just shows above the soil, and be sunk in a bed of a moderate degree of warmth, affording as much water as will maintain healthy conditions in the soil. Plumbago rosea, Clerodendron fragrans, Aralia papyrifera, and Macleaya cordata are amenable to this mode of propagation. These root-cuttings require to be covered with a bell glass. *F. M.*

NOTICES OF BOOKS.

* "LIST OF BRITISH PLANTS."

MR. DRUCE is well known for his many contributions to British botany, and he possesses a critical knowledge of the flora. The present little work may be regarded as an extension—a very great extension—of the London catalogue, and it will doubtless be welcome to those who want detailed lists of species and varieties of the higher plants and Characeæ that occur in these islands. That the list is fairly exhaustive will be seen by the 133 species of Rubus (for example), or the 10 varieties of Capsella Bursa-pastoris, which are here distinguished. We venture to think that in the admission into the *List* of the aliens that may have established themselves permanently or temporarily within the area the author has been somewhat liberal in his hospitality. The Orange, for example, and Iris susiana, not to mention many others, are unexpected guests, and really if we are to include such as these in our flora, it seems hardly worth while to exclude any of our cultivated plants.

We could have wished Mr. Druce had refrained from attempts to reform terminology. We think it useless to attempt to replace the Compositæ by Asteraceæ, or Labiatæ by Lamiaceæ. But if we are to do this, why do not the Cruciferæ appear as Brassicaceæ?

The Vienna rules as to nomenclature of species seem to have been rather spasmodically followed, but we note a rather large number of instances in which the rules are apparently disregarded.

† "THE A.B.C. AND X.Y.Z. OF BEE-CULTURE."

THE alpha and omega of bee-culture, so the name implies! But though the book treats most ably of all that is at present known of every phase of bee-keeping, we have not yet reached the omega of knowledge of one of the most interesting and wonderful of insects. As far back as 1771, Wm. White, of Oxfordshire, called bees, "that nation of chemists to whom nature has communicated the rare and valuable secret of enriching themselves without impoverishing others."

The first edition of the work under notice seemed a wonderful production, but the charm of the older volume fades in comparison with that of the present edition. This latest production is full of rich information, concisely and clearly stated, and at the same time it is illustrated with photographs that show nearly every process of the work in connection with bee-keeping. The matter is in every respect sound and practical. As it is written chiefly for Americans, many of the hints do not apply to bee-keeping in this country, but the main points of the art are the same all the world over, and consequently the book may be read with advantage by bee-masters at home.

The alphabetical form, rendering it, as the authors say, an encyclopædia of everything pertaining to the knowledge of bees, makes it a handy volume for the busy bee man. This does not in any way detract from its value to the beginner, for on page 1 the novice is directed to a course of reading which will be sufficient for one commencing bee-keeping, but no one who desires to make bee culture a success will be satisfied with reading that portion only. The interesting manner in which the book is compiled will of itself compel anyone who reads those few articles selected by the authors to read the volume from cover to cover.

Reviews and comments are printed at the end of the book. The opinions of such apiarists as Messrs. Doolittle and Miller deserve careful attention, for they are men of great practical experience. A study of the work will enable the expert to enrich his knowledge, whilst the beginner will gain an immense amount of knowledge by its perusal that cannot fail to be of great value.

SOME NEW DAHLIAS OF 1907.

OWING to the sunless summer of 1907, very few of the new Cactus Dahlias were seen at their best condition, and it was not till quite late in the autumn that representative blooms were produced, even of the best sorts. Some few varieties failed entirely. The reputed champion variety of the year, Rev. A. Hall, was very late indeed in flowering. The plants grew tall, without producing lateral growths, and before most growers were aware of it, the season was too far advanced for the new growths to flower in time for the Dahlia shows. When the flowers did appear they were exceedingly fine specimens, and gardeners who possess this variety should practise early planting and stopping. One of the most beautifully-coloured of the Cactus section is Lady Malmesbury, a variety having blush-pink flowers, and the additional advantage of holding the blooms quite erect on long stalks. It is also of the best form. Another good variety of the mauve and pink section is Daisy Staples: the flowers are of a medium size, and are composed of very narrow florets; this variety flowers freely. The unique novelty, Lady Fair, is quite a new break in Cactus Dahlias, and well worthy a trial. In addition to the usual florets, there are numbers of small feathery florets, which proceed from the base of the main ones, and they give a very irregular or even ragged appearance, which, if not exactly beautiful, is a novelty. A very useful and free-flowering Dahlia is Kathleen Bryant, which has the additional attraction of being a dark-coloured variety. This also belongs to the Cactus type, and promises to become a popular flower.

Ruby Grinsted is also a very fine addition, although the plant is a shy bloomer. The plants are dwarf and sturdy, and the flowers are held very upright. This is another somewhat late-flowering sort, and the plants should be encouraged to flower early, it is at its best season in early September. The colour is lovely. Amongst the new whites One Flag of Truce is of the purest white, as is also Mrs. H. Shesmith, a variety having very large flowers with long florets of much substance. Another of these light-coloured varieties is Mrs. W. H. Raby, the flower of which is excellent in form, but the colour is creamy. In Dreadnught is seen the largest Cactus Dahlia yet raised: it will not succeed as an exhibition flower in the south, but it is well suited as a garden variety, either when grown naturally or partially disbudded. Those growers who favour the Dahlia as a garden flower should secure plants of E. Cadman, a variety having blooms of an Indian red colour, and of star-like form. It is one of the best to show its flowers above the foliage. A purely exhibition sort is Hyacinth. The florets are a beautiful colour or combination of mauve and pink colours, and the form is excellent. The plants may be grown as robust as possible, as the blooms are never coarse. The rarity of really good dark flowers makes Recam doubly welcome: it has a fault, however, in not flowering with freedom. The blooms are very large and of globular form, the florets being of a first-class shape. As the growth is very robust, a number of main stems may be allowed to remain on each plant, as the flowers will thereby be reduced in size.

Amongst yellow varieties Primrose claims a leading place. In colour the flowers are of a light sulphur yellow. As a variety for all-round excellence it is difficult to surpass. Chaucher, apart from a very weak stem, which spoils it for cutting purposes, is also very fine. The flowers are very large and of lovely pink and white colours. The plants should be allowed to carry almost all the buds and blooms which develop on the main shoots. A welcome addition was seen in Mrs. Cozens, a variety having bi-coloured flowers. The base of the florets are maroon, and they are tipped with white. The plant is not exceptionally robust, and requires careful cultivation.

Two fancy Cactus Dahlias were fairly good: these were Meteor and Diavolo, the first being white speckled and striped crimson, the other yellow, shading to white at the tips, and very thickly speckled and blotched with maroon and chocolate. Both these sorts require a somewhat vigorous thinning of their shoots and flower-buds to obtain the best results. Eureka must also be included amongst the best and most distinct of the new Dahlias, the colour being a deep purple. The flowers are well formed, deep in the centres, and of a great size.

Another large-flowered variety, and one of first-rate habit, is T. A. Havemeyer, the blooms being formed of narrow, incurved florets on tall, stiff stems. The plant has a very erect habit of growth.

In the newer section of Cactus, the Pompon Cactus, several very useful new varieties have been added, one of the best being Gracie, a beautiful and novel little gem of perfect Cactus type. The colours are yellow, scarlet, and white. Of the true Pompon varieties, Rodney, an exquisitely formed flower of deep amber colour, shaded with fawn, and Portia, a beautiful flower of rosy mauve colour, are to be recommended.

Mignon is one of the finest garden varieties yet raised, and may be grown entirely natural, for it requires neither thinning nor disbudding. The colour is bright pink, and is most effective. Although classed as a Pompon Cactus, it is a trifle too large for use as an exhibition variety of that class. The variety Nana, however, is a true Pompon and of true Cactus floret: the colour is dark orange. Nana promises to rank as one of the best in its section. *T. W.*

* *List of British Plants*, containing the Spermophytes, Pteridophytes, and Charads found either as natives or growing in a wild state in Britain, Ireland, and the Channel Isles. By G. C. Druce, M.A., F.L.S.; Oxford, Clarendon Press. Price 2s. 6d.

FOREIGN CORRESPONDENCE.

CARNATIONS IN AMERICA.

REPRESENTATIVES of the trade from all over the United States and Canada attended the convention of the American Carnation Society, held at Washington on January 28 and 29. The society's Gold Medal for 100 blooms of any colour was won by Mr. C. W. Ward, of the Cottage Gardens Co., Queen's, New York, with his variety Alma Ward, thus adding another to his long list of successes. Mr. R. Witterstaether took the Silver Medal with Afterglow. Mr. Rudd, the raiser of Defiance and other fine kinds, had a few blooms of a new white, unnamed seedling. This was much admired by experienced growers present. The flowers of this variety are of a very large size, pure white, and are produced in the greatest freedom. President Seelye is another good white flower, and there was nothing shown in the red classes that surpassed Beacon, Victory being perhaps the nearest. Enchantress still holds its own as the best in its class, but the variety Mrs. T. W. Lawson appears to be rapidly deteriorating. The decision of the Executive Committee to hold its next convention at Indianapolis is a good one, many large growers being located in and around Indiana State. The society is fortunate in its choice of Mr. A. Patten, of Tewkesbury, Massachusetts, as President. *H. K. K.*

The Week's Work.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Cattleyas.—C. Trianæ is now making a pretty show with its flowers. There are many beautiful forms of this species, and so distinct are some of them that it is difficult to recognise them as all belonging to the same type. The plants are easy of cultivation and never fail to produce flowers freely if they are afforded proper treatment. C. Trianæ, perhaps more than any other species of Cattleya, suffers from neglect during the winter months, and this neglect is afterwards apparent both in the quality of the flowers and in the shrivelling of the pseudo-bulbs. Growth begins with the swelling of the flower-spikes in the sheath, and by the time the flowers are fully expanded, the plants are actively growing, notwithstanding that no roots or young shoots may be visible. Especial care is therefore necessary from the commencement in affording moisture to the roots of these plants, for while they do not require an abundant supply of water, they should on no account be allowed to suffer from drought. These remarks also apply to the species C. Percivaliana, which flower a little in advance of C. Trianæ. The beautiful hybrids of the genus Cattleya and the bigeneric Lælio-Cattleyas, which are so numerous and extensively grown for a late winter and early spring display, should have their flowers removed after they have been expanded for a reasonable length of time. After this, any re-potting that is necessary should be done.

Re-potting.—In addition to the above-mentioned kinds that should be examined now are the autumn and early winter-flowering species of Cattleyas, including C. labiata and its varieties, and the hybrids C. Fabia, C. Clarkiæ, C. Iris, C. Statteriana, C. Cornelia, C. Mantinii, C. Ashtonii, C. Pittiana, and others that, having rested since flowering, are now pushing forth new roots. Healthy specimens that have overgrown their receptacles, with the rooting material still in a good condition, may be shifted on into larger pots or baskets. Plants with decaying material about their roots should have all the old compost shaken from them, and any roots that are dead cut away. The strong growing and rooting kinds should be afforded more root space than those that are small in habit and weak in growth, but all alike need ample and perfect drainage. After the root disturbance necessary in shifting and potting, watering must be performed carefully, and the plants will require shading during the hottest parts of bright, sunny days. Frequent damping between the pots, and spraying overhead on all suitable occasions, will greatly assist the plants to quickly recover.

Rooting material.—The overhauling of a batch of plants always gives the cultivator an opportunity of noting what progress the roots have made, and whether the compost provided for them is suitable or not. I do not recommend leaf-soil as a rooting medium, either alone or mixed with other ingredients. The plants grow freely in it, I admit, but the flowers when produced are seldom of good quality. I have for some years past discarded leafmould for the more substantial Osmunda and Polypodium fibre, material now well known and largely used by Orchid growers. Having abundant proof that these materials provide the best rooting medium for these and many other epiphytic Orchids, I do not hesitate in recommending its use. Osmunda may be employed alone for some of the strong rooting kinds of Lælias and Cattleyas, but a mixture of equal parts clean sphagnum-moss, Osmunda, and Polypodium fibre, broken up, and well mixed together, with a good sprinkling of crushed crocks and charcoal, is the best medium for general use. When potting, press these materials moderately firm about the roots, and keep the base of the plant on a level with the rim of the pot.

Back pseudo-bulbs.—During the process of re-potting, all useless pseudo-bulbs should be removed, for if these are allowed to remain they not only rob the other pseudo-bulbs of nourishment, but they also necessitate the use of larger pots than would otherwise be needed. Three or four growths behind each lead is quite sufficient. Should it be desired to increase any of the varieties, the portion thus removed may have a label attached, and be laid on the moisture-holding stage, where they will get frequent syringings. If they eventually start into growth, they should be placed into small pots.

THE KITCHEN GARDEN.

By I. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

The herb border.—Herbs are so essential that special efforts should be put forth to ensure a regular supply all through the season. A well-ordered herb border, with the plants neatly arranged and labelled, is not only useful, but is interesting and pleasing in appearance. The present is a capital time to divide and transplant any of the perennial kinds that may require it, and to clean and apply a good top-dressing of leafsoil and sand to the rest of the species. A plantation of Mint will remain profitable for a considerable number of years if an annual surface-dressing of well-decayed leafsoil is applied. Both the Lemon and Common Thyme delight in a porous soil, nothing being better than road grit for these plants. Endeavour to arrange all the perennial species at one end of the border and the annuals at the other. Most herbs will generally thrive well on an east or west aspect.

Box edging.—Where this is employed it is essential that it be kept within reasonable bounds, and it should always present a neat and tidy appearance. To ensure this condition it is necessary after the elapse of a few years to take up, divide, and replant the plants. This work may either be done during the spring or autumn, but I much prefer the present time. This requires to be carried out by a man with considerable intelligence, and it should be done expeditiously.

Broccoli.—Plants which were laid over during November should be examined for the purpose of removing decaying leaves and stirring the surface soil with the draw hoe. Several varieties will now be "turning in" apace. The heads should be kept covered to prevent them being damaged by frost, and if these should be found to be turning in faster than is required, lift some of them and suspend them in a cool shed. Make a small sowing of the variety Michaelmas White in boxes under glass, and raise the plants in an atmospheric temperature of about 50°.

Brussels Sprouts.—The earlier plantings of these will now have ceased to be profitable. Lose no time in lifting them and burning the stumps on the smother fire. Sow seeds of the variety Sutton's Dwarf Gem in a box, and treat them in the same way as Broccoli.

Leeks.—Plants raised from early-sown seeds will now be much benefited if they are potted on into 5- or 6-inch pots, using a good fibrous loam three parts, and sifted leafsoil or manure from a spent Mushroom bed one part, with sufficient coarse sand to keep the soil porous. Cultivate them near the glass in an atmospheric temperature of about 50°. Sow another box of seed and raise the seedlings in a gentle heat.

Onions.—The ground should be got in readiness for the main Onion bed which is sown in the open. The sooner this seed can be sown, provided the weather is suitable, the more likely will the crop be successful, the later sowings being much more subject to attacks of the Onion fly. The ground, which has been deeply trenched and heavily manured, should now be forked over and given a good dressing of wood ashes and soot. Rake the surface down very finely, and sow the seeds in shallow drills, drawn at 1 foot apart. The soil can hardly be made too firm, especially if it is of a light nature. Among the best varieties for this sowing are James's Long Keeping (still one of the best), Veitch's Main Crop, Improved Reading, and Webb's Masterpiece.

The frame ground.—All vegetable plants which have been wintered in cold frames should now receive abundance of air, removing the lights entirely whenever the weather is favourable, thus preparing the plants, as far as possible, for removal to their permanent quarters in the open garden.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq., Keir, Perthshire, N.B.

Cyclamens.—The earliest plants of Cyclamen that are past flowering should not be thrown away, as is generally done, but kept in a partially resting state in a cold frame for the purpose of utilising them another season. If large plants are desired, the most successful method of cultivation is to plant them out in a cold frame at the end of March. The frame should be filled up with soil to the slope of the light with a compost of rich loam from an old pasture, leaf-soil, manure from an old Mushroom-bed, wood ashes and sand, well mixing these ingredients together. The old soil should be carefully shaken from the roots before planting them into the frame, care being taken to work the fresh soil well in amongst the roots, and to press its fairly firm round about the corms; but the top of the corm should be kept clear of soil. After the planting one good watering should suffice until growth is freely started. The plants should be syringed in the afternoon daily, and the frame closed at the same time to retain all the sunheat possible. Afford a little shade during the middle of the day if there is bright sunshine. Plants raised from seeds sown last autumn should now be ready for potting-on into 3-inch pots. A compost similar to that described above, but in a finer condition, will be suitable. Place the plants in an atmospheric temperature of 60° to 65° at night. Syringe them freely to keep thrips in check, as they are very troublesome whilst the plants are being grown in a warm atmosphere, and this is necessary until the roots have obtained a good hold of the soil. After that stage place them on a bed of ashes in a cold frame. In gathering flowers of Cyclamens, they should be pulled, never cut, as the small piece left on the plant generally damps back and rots, causing decay to the remaining young flowers.

Chrysanthemums for large blooms.—These plants should now be all potted into 3-inch pots and kept growing slowly. They require to be strong, yet without grossness. If they are cultivated in an exposed position to sun and air, as recommended in a previous article, it is advisable to look over them twice a day to ascertain which plants may require water. This should be done in the early morning, and again early in the afternoon; on each occasion syringing the plant gently overhead, and damp the surfaces in the house if the weather is bright. Front air may now be admitted a little at a time on all favourable occasions, but take care to prevent cold draughts. The plants should be turned round once a week to the sun, as this helps the wood to mature as it grows, which is essential. Strict attention must be given to keep green fly in check. Attention to all minor points in detail is necessary. Never use fireheat if an atmospheric temperature equal to 45° can be maintained at night.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Cannas.—Old roots should now be cleaned of dead foliage, &c., placed in shallow boxes, and covered with leafmould. A newly-started vinery is a very suitable place in which to start them into growth. No water will be necessary until some of the new shoots have appeared. Should it be necessary to increase the stock, it is best done when growth has started. Few plants are easier of propagation than the Canna, and few are more ornamental and useful in the flower garden. They are suitable for planting in the sub-tropical garden by the edges of lakes or streams, for massing groups and for ornamenting the flower border. Sparsely intermixed with Hyacinthus candicans, Gladiolus brenchleyensis, and Lobelia cardinalis, their large, beautifully-tinted foliage is very effective.

Single beds.—These are very effective when dotted about the pleasure grounds. In planting them endeavour to produce a variety of effect by the use of flowering and foliage plants indiscriminately. One may be occupied by Acer atropurpureum, with a groundwork of Heuchera sanguinea, and Anemone japonica; another with Spiræa Anthony Waterer, with Primroses, Daffodils, and Hyacinthus candicans. Japanese Irises with Aubrietia purpurea and Tulip Murillo, is a suitable mixture for another; whilst Genista Andreana, both standard and bush plants, with a groundwork of Centaurea candidissima, and Gladiolus brenchleyensis, or Hydrangea paniculata, with Lilium croceum, L. tigrinum, L. Fortuni, L. giganteum, together with a groundwork of Violas, form other suitable combinations.

Lawns.—In order to have a well-kept lawn it is necessary that the broom and the roller be frequently applied. At this season of the year the turf will be benefited by a dressing of finely-sifted soil, leafmould, wood ashes, and soot. This mixture should be scattered evenly over the surface sufficiently thick to be well seen, and when dry brushed into the turf with a birch broom. The making of new lawns, when good turf is procurable, can practicably be accomplished at once. The work of turf laying is best completed this month. Fine soil should be sprinkled over the newly-laid turves and be well brushed into any crevices before the roller or beater is applied. If it is intended to form the new lawn from seeds they may be sown early in March, if the weather is mild and showery, but the ground should be first properly levelled and allowed to settle. Procure the best possible grass seeds for the purpose. Lawns can be rid of worms by applying one of the many worm killers on the market.

Pæonies.—The mulch that was placed around these plants in the autumn should be lightly forked in when the young growths appear. Herbaceous Pæonies are not over particular in the matter of position or soil afforded them, but being gross feeders, a rather moist position is preferable, and, for the benefit of the flowers, one having a slight shade. Autumn is the best time for planting Pæonies, but if necessary they may be divided and planted in the spring as soon as the new growths can be seen, but it should be remembered that these plants succeed best when they are undisturbed for several years. In planting they should be placed not more than 1 or 2 inches below the surface of the soil, and from 2 to 3 feet apart. The Tree Pæony will succeed under similar conditions to the herbaceous varieties, with the exception of some of the more tender varieties. In their case a little protection should be afforded them in winter, and their propagation from cuttings or grafting is necessary.

The herbaceous border.—The practice of dividing plants with the spade, except in the case of such fast-growing subjects as Phloxes, Helianthus, Asters, Achilleas, &c., which require very frequently to be divided in order to confine them to their quarters, should never be adopted. The better plan is to drive two forks (back to back) into the plants, and to pull them into as many parts as is desirable. In order that the border may be well furnished during the flowering season, it is not desirable to disturb more plants than is absolutely necessary. Give a dressing of short manure to the border, and lightly fork it in.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

General work.—Work in the hardy fruit garden is still of a preparatory character, but, at the same time, most important, as the more effectively things can be pushed forward now the less there will be to do when the staff ought to be otherwise busy. Advantage should be taken of frosty mornings to have all trees that require it mulched and manure wheeled on to the borders. Mulchings for fruit trees should be composed of rich manures, but at this season it is better to apply it in two or three dressings, as the manure makes heavy soils cold and wet. Mulches applied to recently-planted trees should be for the purpose of retaining the moisture in the soil, and should preferably be of a light nature, as newly-planted trees should become fruitful before they are afforded rich manures of any kind. The nature of the soil and the condition of the roots should determine the kind of manure that is used, for it is of no use applying rich mulches if the roots are not in a condition to receive the manurial properties. A free dressing of lime and wood ashes applied to soils that are cold and of a retentive nature is preferable to mulching at this early season. Young trees that were planted against walls in the autumn should be pruned and tied without delay, as the soil about them will have settled down by this time. Opinions differ widely amongst gardeners as to the best system of pruning newly-planted Peaches and Nectarines. It is better to defer their pruning for as long a period as possible, and to merely shorten any misplaced shoots to well-ripened buds, or any that detract from an evenly-balanced tree. If any further pruning or spraying of fruit trees is necessary, this should be completed at the first opportunity, as the buds will be bursting soon, when it will be dangerous to carry out this work without injuring them. Examine recently-planted trees in the orchard, and make secure all ties and stakes, placing hay bands around the stems to prevent them being injured by the action of the wind. If hares or rabbits are troublesome, protect the stems with bunches of furze or pieces of wire netting. Small birds are often troublesome at this season, especially to Gooseberries, Currants, and Plums. Dust the bush fruits with lime and soot in the early morning, when the bushes are moist, or net them over, if this can be done. Plum trees should be syringed with quassia extract or some other distasteful preparation. Examine the Black Currant bushes at short intervals for "big bud," which must be picked off and burned.

Vines should be pruned and trained during this month, for if their pruning is deferred much later the cut surfaces will bleed and much energy of the plant be lost. In training the shoots allow plenty of room between them in order that the sun's rays and air may readily reach them. Last season was a most unfavourable one for Grapes in the open.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Strawberries.—The young fruits will, after the trusses have been thinned, supported, and exposed to the sun, quickly swell. The plants should be kept quite near to the glass in a house having a night temperature of from 65° to 70°, with a slight increase by day; with the sun's warmth it may be allowed to reach 85° to 90°. Our earliest plants, that are accommodated upon shelves in Pine houses, have their fruits well advanced. Syringing the foliage both during the mornings and early afternoons of fine days accelerates the swelling of the fruit, and prevents attacks of red spider. Close attention must be given to watering the plants, and it may be necessary to do this two or three times daily in bright weather. It is also important that liquid manure be frequently applied, or, less often, a light top-dressing of some quickly-acting artificial fertiliser. The temperatures should be slightly lowered by affording increased ventilation; syringing of the plants and the application of manures must be discontinued directly the fruits commence to change colour. Strawberries, to acquire their full flavour, should be perfectly ripened, and when gathering them this must not be overlooked.

Pineapples.—Fruiting plants of Queens that were started at the beginning of the year are now developing their fruits. They should be grown in a night temperature of 70°, with a corresponding rise by day. While the plants are in blossom maintain a moderately dry atmosphere, and upon favourable occasions ventilate the house early in the day, closing it again sufficiently early in the afternoon to conserve the solar heat. As soon as the flowering season is over, increase the amount of atmospheric moisture by damping at suitable intervals all the available surfaces about them, and when the house is closed for the day, lightly spray the plants overhead, and damp the surface of the bed with tepid water. At this season carefully remove all suckers and "gills" at an early stage of their growth, and keep the fruits erect by the aid of stakes. Care should be taken to keep the soil in an equably moist condition, but by no means wet, and when watering is necessary use tepid water mixed with enough Peruvian guano to well discolour it. After giving various fertilisers a trial, I have found none other better than this guano.

Late vineries.—Houses devoted to late-keeping Grapes, such as Lady Downes, Black Alicante, and Appley Towers, that require a long season in which to mature their fruit and wood, should now be closed. At the outset the sun's warmth will be sufficient to start the buds into growth. On bright days damp the rods, the walls of the house, and the borders twice daily: carefully ventilate the houses to prevent excessive warmth. Other conditions being favourable, the early growth promoted by these means will be satisfactory, and artificial warmth will not be necessary until the buds burst. Owing to the roots not becoming very active until leafage has advanced, the borders, provided they are now moist, will not require watering until that stage is reached. Young rods of vines of any description should have their upper parts bent down in order to check the flow of sap upwards, and to cause the buds to break regularly in the lower parts.

Late Black Hamburgh house.—The vines in this house receive a more natural period of resting and other advantages, as compared with most other varieties of Grapes. In cases where this Grape is required very late in the season, the vinery should be kept open until the buds begin to burst. Given subsequent good treatment, the vines will have ample time in which to perfect their crops, and to mature their wood.

THE APIARY.

By CHLORIS.

Making a start.—Although a person may be very little learned in the art of beekeeping, I do not think anyone would commence by keeping their bees in the old straw skeps, picturesque though they may appear. A bar frame hive of a standard size and pattern, in order that the parts may be interchangeable and be easily movable, should be chosen. If the prospective apiarist has a knowledge of carpentering, it will be best to purchase a hive as a pattern, and then to make any additional ones required. One or two hives will be sufficient for a start. The hives should be obtained or made at once and be fitted up ready, so that they may be used directly they are required.

Purchasing the bees.—When April arrives a skep of bees may be purchased with advantage, for in April there is less chance of the combs breaking down, because at that early season they will contain very little honey. Much care is needed when purchasing bees, as a disastrous disease known as "foul brood" is very prevalent, and a stranger might take advantage of an ignorant or unwary purchaser. If possible, an old beekeeper should be asked his advice before buying bees. There should be no difficulty in getting such aid, for beekeepers as a body are very ready to assist beginners. The bees when brought home should be driven from their old straw skep and be hived in the wooden hive already spoken of. Another method of commencing is to purchase a swarm as early as possible, approximately in May. Swarms may be purchased from the bee-appliance makers by weight, and these traders will furnish a written guarantee that the bees are free from disease.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR MARCH.

TUESDAY, MARCH 3—
Roy. Hort. Soc. Coms. meet. Nat. Rose Soc. Com. meet. Nat. Amateur Gard. Assoc. meet

THURSDAY, MARCH 5—
Exhibition of Colonial Fruits at Roy. Hort. Hall, Westminster (2 days). Linnean Soc. meet.

SATURDAY, MARCH 7—
Soc. Franç. d'Hort. de Londres meet. German Gard. Soc. meet.

MONDAY, MARCH 9—
Ann. Meet. United Hort. Ben. and Prov. Soc.

TUESDAY, MARCH 17—
Roy. Hort. Soc. Coms. meet. British Gard. Assoc. Ex. Council meet.

THURSDAY, MARCH 19—Linnean Soc. meet.

SATURDAY, MARCH 21—German Gard. Soc. meet.

WEDNESDAY, MARCH 25—
Roy. Bot. Soc. Exh. at Regent's Park.

TUESDAY, MARCH 31—
Roy. Hort. Soc. Coms. meet., and Exh. of Hyacinths at Hort. Hall.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich 40·7°.

ACTUAL TEMPERATURES—

LONDON.—*Wednesday, February 26* (6 P.M.): Max. 49°; Min. 38°.

Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London—*Thursday, February 27* (10 A.M.): Bar. 29·7; Temp. 48°; Weather—Fair.

PROVINCES.—*Wednesday, February 26* (6 P.M.): Max. 49° Cornwall; Min 42° Scotland N.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—
Sale of Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY AND FRIDAY—
Herbaceous Plants, Lilies, Hardy Bulbs, &c., at 12; Roses at 1.30, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

WEDNESDAY
Hardy border Plants and Bulbs, Liliums, Gladiolus, &c., at 12; Roses and Fruit Trees, at 1.30; Azaleas, Palms, &c., at 5; Japanese Liliums in cases as received, Miscellaneous Bulbs and Plants, at 1, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

FRIDAY—
Importations of Vanda cærulea and Burmese Dendrobes, Orchids in flower and bud, by Protheroe & Morris, at 67 & 68, Cheapside, E.C., at 12.45.

The Culture of the Rose.

In view of the universal cultivation of Roses in English gardens, and the increased interest now taken in Rose exhibitions, it is scarcely a matter for surprise that additions to the literature of the flower are made at frequent intervals. There is a quality in the Rose that enables it to appeal to the more cultured tastes, and for this reason, perhaps, the special works setting forth the best systems of cultivation are of exceptional merit, as the contributions from the late Dean Hole, William Paul, Rev. Foster Melliar and others abundantly prove.

Every new writer on this flower finds it a matter of considerable difficulty to treat in a satisfactory manner the question of classification. Many of the finest Roses have been raised from varieties whose ancestors have been so crossed and recrossed with each other that it is impossible to say with any degree of certainty whether they should be classed as Hybrid Perpetuals, Hybrid Teas, or Teas. Rosarians still use these definitions, but a glance through the first part of the latest work* on Rose culture confirms us in the view that the time cannot be far distant when one or other of these divisions must disappear. Mr. Pemberton states that the varieties constituting these three divisions have been obtained from the species Rosa gallica, R. damascena, R. centifolia, and R. indica.

The first Hybrid Perpetuals made their appearance about the year 1840, and became general favourites for fifty years afterwards. The tea-scented Roses were introduced at about the same time, but they were fewer in number and less hardy and vigorous than the H.P.'s; consequently they were not so generally cultivated. The next step was made when certain Hybrid Perpetuals were crossed with the tea-scented varieties, this cross resulting in the production of what are known as the Hybrid Teas. These are perhaps the most valued Roses at the present time, for some of the best qualities of both parents are combined in many of the better-known varieties.

In the earlier part of Mr. Pemberton's book many of the wild Roses of this and other countries are described, and they constitute a large and at the same time a most varied and interesting group. Incidentally, we notice in the first chapter an exhortation to bear in mind that the Rose is not an exotic, but the author in subsequent chapters shows that the Hybrid Perpetuals, Hybrid Teas, and Teas have been obtained entirely from exotic, that is from foreign, species! The wild species are but seldom seen in ordinary gardens, doubtless owing to their single flowers, and to their blooming only once in the year, but many of them are, nevertheless, worthy of general cultivation. For instance, Rosa spinosissima, the Burnet Rose of Scotland, R. alpina, a thornless Rose and one of the earliest of all to flower, R. moschata, the Musk Rose, R. macrantha, R. multiflora, R. rugosa, the Ramanas Rose of Japan, and R. Wichuraiana, the trailing Rose. From some of these species, and more particularly from R. multiflora and R. Wichuraiana, many of the finest, strong-growing, rambling Roses have been obtained, and their latent capacities for producing still more beautiful varieties of the same type have not as yet been nearly exhausted.

The earlier portion of the work under review is chiefly interesting to the Rosarian from the fact that it shows how few species have so far been employed by the hybridist for raising distinct races of Roses. Mr. Pemberton draws special attention to this point, and suggests that crosses should be made between the Hybrid Perpetual and Hybrid Tea varieties and such species as Rosa multiflora, R. rugosa and R. Wichuraiana. He pictures the possibility of having the darkest red Hybrid Perpetuals with a habit like R. multiflora, and magnificent Tea Roses produced on bushes like R. rugosa. Imagine a perpetual-flowering Crimson Rambler bearing clusters in the finest stage of development of such flowers as Général Jacqueminot or Horace Martin!

The present popularity of the Rose is, no doubt, largely due to its apparently inexhaustible capacity for variation. Already there are Roses for almost every purpose for which a flowering plant could possibly be required. For example, there are dwarf-growing varieties for the rockwork, rampant climbers for covering arches and pergolas, others suitable for forming hedges and screens, to trail down banks, to climb up trees, to screen unsightly walls and buildings, or to form beds. Again, there are others which can be grown as standards, weepers, or bushes, and they may be planted with other flowers in borders. Besides these, many are valuable for forcing in greenhouses during the winter season of the year.

Seventy years ago there was scarcely a single Rose which flowered more than once in the year, hence the welcome accorded the advent of the Hybrid Perpetuals, many varieties of which afforded a second crop of blooms, although the later flowers, at least in the case of some of them, were produced but sparingly. At the present time many modern Roses flower almost continuously throughout the season. The improvement in colour has been equally great, nearly every tint, except that of blue or black, being represented.

Much still remains to be done, for many of the newer varieties lack hardiness, while others are of feeble growth, or are sadly wanting in fragrance, while too many fall easy victims to the Rose mildew. Then again we urgently need some perpetual-flowering climbing Roses. There is also one class of colour which is but poorly represented, namely, the clear shades of yellow and orange. There are many varieties which are said to have yellow flowers in the Rose catalogues, but they are only yellow in name, for on the blooms opening they rapidly fade to almost a white.

The second, and more practical, part of Mr. Pemberton's work deals in the following order with the soil and its treatment, with manures, planting, pruning, budding, cuttings, grafting and layering, also with raising Roses from seed, growing them for exhibition, exhibiting them, judging them, growing them under glass, and finally with Rose pests.

When writing of soils, he says: "No amount of good cultivation, however, take what pains you may, can ever compensate entirely for an adverse season and climatic difficulties. In nine cases out of ten it is not the soil but the climate to which success is primarily owing." No doubt Mr. Pemberton refers in that passage more particularly to growing Roses for exhibition, and his contention is certainly well supported by experience. Other things being equal, climate must always be the leading factor in successful exhibiting. In treating of the composition of the soil, he says: "Where a soil is deficient in but one of the five essential ingredients necessary for the plant, although rich in the other four, it may become more or less barren. In other words, it is the body *in minimo* which rules the crop—a most important principle." This statement is equally true of all other crops, and the cultivator who fails to appreciate the fact is sure to incur loss in the application of manures. Mr.

* *Roses, their History, Development and Cultivation*, by Rev. J. H. Pemberton.

Pemberton has not written exclusively for exhibitors, but a great part of his book has reference to the cultivation of Roses for garden decoration. In regard to pruning climbing Roses, he asks: "But what of the old shoots which have just given us masses of flower?" In the majority of cases this growth has done its work; it will either flower no more or flower feebly, the new outgrowth has been sent up to replace it. Therefore, the cultivator is advised to cut out the old shoots as soon as the flowering season has passed.

Mr. Pemberton's view of the usefulness of the Rose is much wider than that set forth by the late Mr. Foster Melliar in his *Book of the Rose*. Mr. Foster Melliar, devotee though he was, confessed that, in his opinion, the Rose was not a good garden plant, and for furnishing a display of flowers for garden effect it could not rival many other species of plants. He therefore insisted on regarding his garden as existing for the Rose rather than the Rose for the garden, content if, amongst the numerous plants bearing partially-decayed flowers, as was their wont, he was fortunate enough to discover one perfect bloom! Mr. Pemberton's appreciation for the Rose as a good garden plant, however, finds considerable justification in the large number of perpetual-flowering Hybrid Teas that have been raised since Mr. Foster Melliar's book was written.

At the end of the volume will be found descriptions of about 200 selected Roses for both garden and exhibition purposes, and we need hardly say that, in these selections as well as in the details of cultivation and methods of exhibiting related in this work, the author speaks with the authority of one who has spent all his life in acquiring practical experience in the subjects upon which he has written.

OUR SUPPLEMENTARY ILLUSTRATION.—The ancient vine at Hampton Court of which we give an illustration in the supplement to the present issue has been seen by hundreds of thousands of visitors to the celebrated gardens, but it still retains its interest for the general public and fruit specialists. The appearance of its huge, quaintly-shaped stem near the ground is sufficient to show that it is aged, and it is generally assumed to be slightly in excess of 150 years of age. That may be no great age for a Yew or other forest tree, but, seeing that during its life this old vine must have produced many score thousands of bunches of fruit, it is surprising that it should still be alive. As a matter of fact, it is now very much more than alive, for it is exhibiting renewed vigour and strength, so that those who remember its condition some 20 years ago admit that it now no longer induces fear that its end is near, but that present appearances seem to indicate that the life of the vine will be prolonged for a very long period. It was a fortunate circumstance that the former condition of the old vine and the unfitness of the habitation came under His MAJESTY'S notice. The result has been that under the superintendence of Mr. MACKELLAR, His MAJESTY'S gardener, the old vinery has been removed, a new and far more spacious and lighter structure has been built, and this now shelters the vine. With the removal of the old house there was also a thorough clearance of the mass of brick flues and base walls that so largely occupied the vinery floor. The space thus occupied has since been filled with good soil, some being sent from Windsor Park, thus creating, as it were, an expansive and new root area for the vines. Under the care of the veteran custodian, Mr. JACK, the vine has liberally responded to the better conditions. When the late Mr. BARRON wrote his famous book, *Vines and Vine Culture*, in 1883, he mentioned that the Hampton Court vine carried as many as 1,700 bunches in a season. It is no wonder that evidences of exhaustion followed such inconsiderate cropping. If the vine now carries only about 400 bunches yearly, they at least excel greatly in size those of earlier years; the berries are very fine, as black as Sloes, and of true Hamburgh flavour. Last year many of the bunches ranged from 2 lb. to 2½ lb., thus telling a very different tale from the poor, little, half-pound bunches that formerly formed the annual crop. It was a wise step to exclude visitors from the interior of the house, and permit them to view the vine from the glazed lobby shown in the inset in our illustration. Formerly visitors caused so much dust that the Grapes became coated, and had to be washed before they were distributed as gifts. The foliage also necessarily greatly suffered. Now not only are the Grapes as clean as are those grown in any private vinery, but they are so excellent in quality that they are specially reserved for the Royal table. At the present time the house is liberally ventilated and kept as cool as possible, that the crop may hang late into the autumn. The young wood made last year is wonderfully good and promising. The old vine, in its remarkable resuscitation, is an example that should be noted by Grape growers.

ROYAL HORTICULTURAL SOCIETY.—An exhibition of Colonial-grown fruit and vegetables will be held at the Hall in Vincent Square, Westminster, on March 5 and 6. Sir SOMERSET FRENCH, K.C.M.G., the newly-appointed Agent-General for the Cape Colony, and previously Postmaster-General for the Cape, will perform the opening ceremony, which will take place at 12.30 on March 5. Entries for many exhibits have been received, and include fruits (Plums, Pine Apples, &c.) from South Africa, Apples from Nova Scotia, Bitter Oranges and other citrus fruits from Cyprus, and also South African and Mediterranean preserves, cheeses, jellies, and honies. Sir SOMERSET FRENCH will show a large collection of paintings of Cape scenery executed by Cape artists. Mr. C. DU F. CHAPPINI, the Trade Commissioner for the Cape, will give a lecture at 3 p.m. on March 5 in the lecture room at the Hall on "Cape Colony and its Commercial Fruit Resources." The band of His MAJESTY'S King's Colonials will be in attendance on both days under the conductorship of Captain PETER C. ANDERSON.

———We are informed that Mr. A. W. SUTTON will deliver a lecture on "Tuberous Solanums" before the Scientific Committee in the Lecture Room at Vincent Square at 4 p.m. on Tuesday next.

THE BRITISH ASSOCIATION.—The meeting of the British Association for this year will be held in Dublin from September 15 to 22. The president for the year is Mr. FRANCIS DARWIN, F.R.S., so well known for his investigations on plant physiology. Mr. F. F. BLACKMAN, F.R.S., who, by a curious coincidence, has also specialised in the direction of plant physiology, will preside over the botanical section of the Association. It is expected that there will be a strong gathering of botanists at the meeting.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT SOCIETY.—The annual meeting of this society will be held at the Royal Horticultural Society's Hall, Vincent Square, Westminster, on Monday, March 9, at 8 p.m.

HORTICULTURAL CLUB.—The next house dinner of the Club will take place on Tuesday, March 3, at the Hotel Windsor, when Mr. C. E. PEARSON will give a lecture, illustrated by lantern slides, on bird eggs and evolution of protective colour.

LINNEAN SOCIETY.—A meeting of this society will be held on Thursday, March 5, when the papers will be read by Prof. F. E. WEISS, D.Sc., F.L.S., on the "Morphology of Stigmaria in comparison with recent Lycopodiaceæ," and Mr. ALEXANDER PATIENCE on "Trichoniscoides albidus and T. Sarsi."

CONTINENTAL RAILWAYS AND HORTICULTURE.—A circular letter has been addressed to persons interested in horticulture to the effect that a certain number of railway vans are in course of construction which will be heated during cold weather, to enable flowers and living plants to be safely transported over the European railway system. They will be used over the international routes as defined by the Berne agreement in 1886.

FLOWER SHOWS IN AMERICA.—The special prizes to be given at the National Flower Show to be held at Chicago in November next already amount to over $2,000 in value. American growers are actively preparing for the show of the National Rose Society, to be held in the same city next month, and the year 1908 promises to be a notable one in American horticulture generally.

AMERICAN SPECIES OF CRATÆGUS.—We have received a monograph of the *Crataegus in Southern Michigan* from the pen of Professor SARGENT. It gives detailed descriptions of no fewer than 55 species, and the author observes that "it seems probable that there are still in the southern part of the State a large number of unnamed species." When we remember that all these come from a portion of one State, and that among them only three names familiar to cultivators occur, namely, punctata, mollis, and tomentosa, it is evident that Michigan is extraordinarily rich in Cratægus not known in gardens. Whilst this is undoubtedly the case, one is inclined to wonder whether American botanists are not splitting up their material rather finely—in other words, creating several species where one would serve. For our part, we suspect they are doing what British botanists have done with our native Rubi. The latter have founded species on such trivial characters or combinations of characters that the study of Brambles on their lines is hopeless for students of ordinary opportunities. They have brought matters to such a pass that there are, perhaps, three people in the country who can profess to know Rubi thoroughly. Some will regret this tendency on the ground that, being so difficult of practical application, it makes descriptive botany impossible to the ordinary man and tends to divorce the science from horticulture. Professor SARGENT'S descriptions are evidently made with exceeding care and minuteness, and characterised by that thoroughness which marks all his work. From two-thirds to a page is devoted to a technical but plain description of each species. A conspectus of the species in each group, giving their differentiating points, precedes the specific descriptions. But we note these points are often of inferior importance, and confirm the doubts expressed above. For instance, in the group Tenuifoliæ, the only difference mentioned (and from its place in the conspectus we presume it is the chief difference) between *C. glaucophylla* and *C. otiosa* is that the leaves of the former are "deeply lobed," the latter "slightly lobed." This seems hardly a character of sufficient importance to confer specific rank.

FRANCO-BRITISH EXHIBITION.—We understand that the French government proposes to set aside the sum of 795,000 francs (£31,800) to enable the State industries to be represented at the forthcoming exhibition in London. The Minister of Agriculture, with the aid of 100,000 francs, will provide for the suitable display of exhibits connected with French agriculture and horticulture

SCHOOL OF FORESTRY IN THE FOREST OF DEAN.—The School of Forestry which has been established by the Commissioner of Woods and Forests in the Forest of Dean is reported to have made satisfactory progress. There are now 14 men at the school, of whom six came from private estates and eight were Crown labourers in Dean Forest. Up to the present 13 men have passed through the school, and of these three have obtained situations as assistant-woodmen in the Royal forests, one as assistant pole inspector in the Post Office, and two as head woodmen on private estates. SIR E. STAFFORD HOWARD, in his Report for 1906-7, observes that there appears to be a satisfactory demand for the education given, though the school is still unknown in many parts of the country. The applications received for trained men show that there is a demand for the services of qualified woodmen. *Journal of the Board of Agriculture*, February, 1908

MARRIAGE.—The marriage of Mr W. T. LAWRENCE, the eldest son of SIR TREVOR LAWRENCE, took place on Monday last, the 24th inst. The wedding ceremony was a floral one. The bride wore a large cluster of English-grown Orange Blossoms, and had a tiara-shaped wreath of the same flowers on her head. The bridesmaids carried posies made of Zonal Pelargonium flowers, relieved with sprays of Erica persoluta alba and foliage of Pelargonium quercifolium.

GREVIA SUTHERLANDII.

THIS singular plant forms a small tree, and is a native of Natal, from which Colony it was introduced to our gardens about the year 1859. The name of the genus Grevia was given in honour of Sir George Grey, K.C.B., Governor-General of the Cape Colony at the time of its discovery, and the specific name is after that of its discoverer, Dr. Sutherland, who found it growing at much-exposed headlands 2,000 to 6,000 feet above the sea level. Grevia is now regarded as a member of the Nat. Ord. Sapindaceæ. The leaves are clustered at the ends of the branches, are cordate, orbicular-ovate, fleshy, glabrous, bright green and notched at the margins. The flowers are drooping, scarlet in colour, each about half an inch in diameter, and the inflorescence, which in greenhouses in this country occupy about two months in developing, form dense terminal clusters at the ends of the branches. Remarkable cup-like discs intervene between the petals and the stamens, and along the edges of which are ranged a number of stalked glands, the rudiments, probably, of abortive stamens. The species flowered for the first time in Europe with the late Dr. Moore, of Glasnevin. It has recently flowered in Sir E. G. Loder's gardens at Leonardslee, Sussex, and the gardener, Mr. W. Cook, has obligingly sent us an inflorescence, with the following information

"The specimen forwarded has been grown in a well-ventilated greenhouse having an atmospheric temperature of 50° to 60°, and in full exposure to the sun. During the winter months the house is kept rather dry, as at this period the plants are in a condition of rest. A suitable rooting medium consists of a mixture of loam and peat-soil, with a free admixture of silver sand. The foliage is benefited by frequent sprayings of water during the summer months. The plant is not susceptible to attacks either by insects or diseases. Propagation may be readily effected by cuttings."

COLONIAL NOTE.

PARA RUBBER IN CEYLON.

AN interesting account is given in an article that has recently appeared in the *Tropical Agriculturist* of the way in which the Para Rubber plant was introduced into cultivation in Ceylon. Mr. H. W. Wickham, who was engaged in planting in tropical America, was commissioned by the Government of India, acting on Sir Joseph Hooker's suggestion, to procure the seeds of the tree, in order that it might be tried in our Eastern possessions. Mr. Wickham owed it to a fortunate (for him) accident that he was able to bring a considerable quantity of seed home in the year 1876. The Inman Line commenced to run a steamship in connection between Liverpool and the Hugon. The first vessel which sailed after reaching the Upper Amazon met with trouble, and was left on the captain's hands, with no cargo for her return journey to Liverpool. Mr. Wickham therein saw his opportunity, and wrote at once to charter the ship on behalf of the Government of India, and directed the captain to be at the juncture of the Tapajos and the Amazon rivers at an appointed time. Meanwhile he set to work in the forest, with what help he could procure, to collect the seeds. These were packed, after drying, in openwork baskets made by the native women. The task of drying the oily seeds and afterwards keeping them properly ventilated required much care, and the limited time available added considerably to the difficulties. The seeds had to be conveyed in canoes to the ship at the mouth of the Tapajos. The crates were slung up in the fore hold of the vessel, and started on the homeward journey. Owing to the good offices of a friend at court, the risk of delay raised on the part of the Portuguese authorities was successfully obviated, and the seeds arrived at Kew in June, 1876. The work of planting was immediately commenced, and shortly afterwards a crop of 70,000 young Hevea plants was to be seen in the glasshouses. The first locality decided on for the destination of the seedlings was Tenasserim, in Southern Burma, but, owing to adverse circumstances, it was finally decided that they should be forwarded to Ceylon. The young Hevea plants were therefore carefully packed in Wardian cases and placed on board British India liners. There was considerable difficulty at first to persuade the planters that the Para Rubber trees did not require a swampy situation, as it was generally understood that the plants naturally inhabited such localities. This seems probably to have been due to the hasty inference drawn by an "explorer" from a few weeks' experience on the Amazon, who had seen a few plants growing in the river swamps. The real fact, however, is, that the trees occurring in the wet lands have strayed from the main Hevea forests, which occupy the higher dry land behind. Much time was consequently lost in the first instance. The report of the man who really knew the forest seems not to have reached the

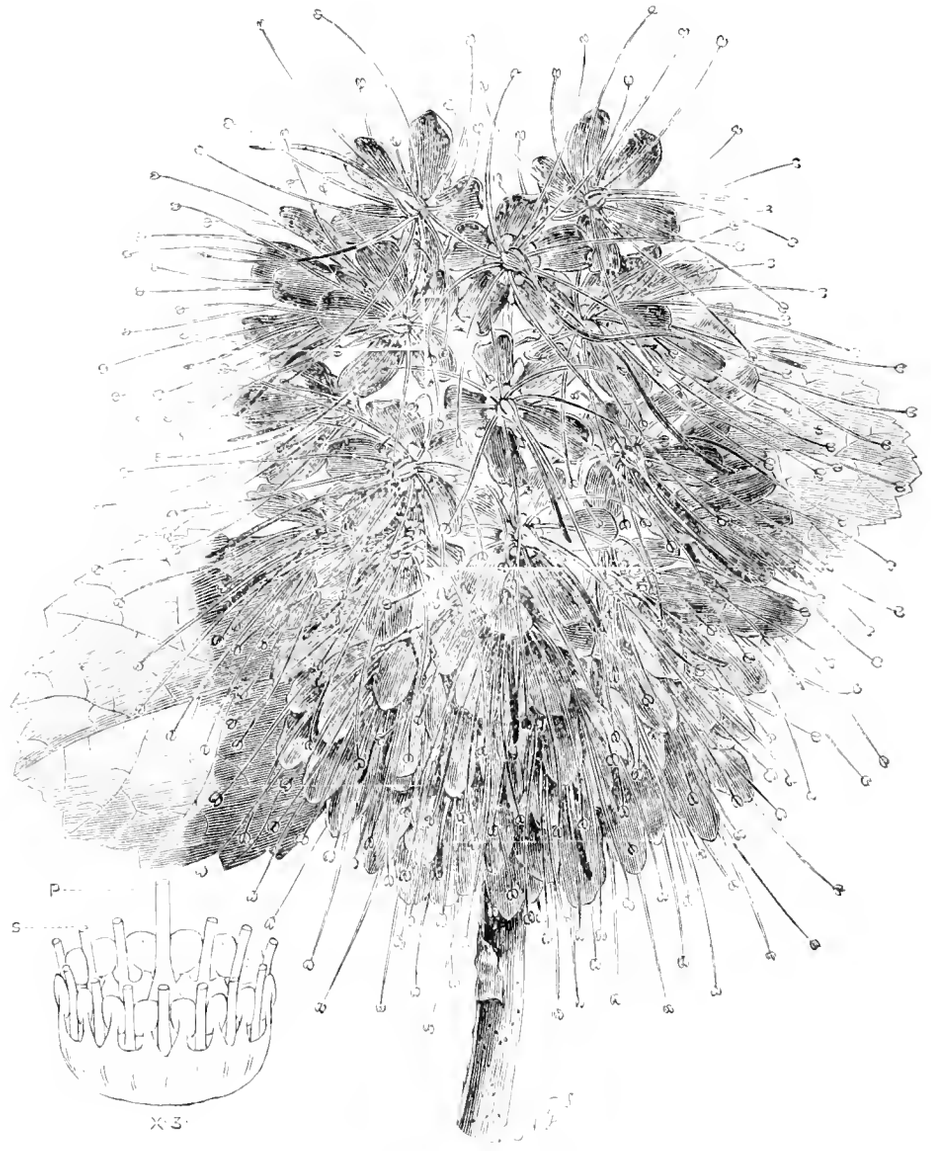

FIG. 54.—GREVIA SUTHERLANDII: FLOWERS SCARLET.

planters, but to have been overshadowed by erroneous information from other quarters. It is gratifying to remember the important part played by the Royal Gardens, Kew, in the introduction of this source of wealth in our Eastern possessions, but it should also not be forgotten that this is only one of the many great services which Kew has rendered to the Empire.

FIG. 55.—LEONOTIS LEONURUS: FLOWERS ORANGE-SCARLET.

LEONOTIS LEONURUS.

THIS is an old inhabitant of our gardens. Its popular name is the Lion's Tail plant. At the exhibitions of the Royal Horticultural Society within recent years Messrs. Veitch have frequently exhibited the plant as a winter-flowering greenhouse subject. In Wood's *Natal Plants*, Vol. I., p. 53, it is stated that in Cape Colony it is known as the Wild Dagga, and in Turkey as the Minaret Flower, an appropriate name. The following interesting statement by Dr. Andrew Smith is also quoted: "The Kaffir name, 'umfincafincane,' is taken from the sugar-birds sipping the sweets from the bottom of its long, trumpet-shaped corollas. Before the mouth of the corolla opens, which it does when the stamens are mature, the nectar is intensely bitter, but at the moment of opening the sweetness is developed. This means that nature does not wish insect marauders who cannot carry the pollen where it is required to come and rob the nectary."

A decoction of the plant is used as a medicine by the natives of Natal, and the Hottentots smoke the leaves like tobacco.

Leonotis Leonurus is a soft-wooded plant 4 to 6 feet high, with erect quadrangular stems, rounded at the angles, and furnished with opposite, oblong, narrow leaves with clusters of smaller ones in the axils. The leaves taper at the base to a short petiole, and have a few blunt teeth towards their apices; the surface is finely pubescent above, and densely so beneath.

The flowers, produced in dense whorls in the axils of the uppermost leaves; they are tubular, covered with short hairs on the outside, of a rich, bright orange-scarlet, and very showy. A succession of whorls is produced, so that if the dead blooms are picked off the plants remain in a decorative condition for a considerable period; moreover, the whorls of empty calices which remain in no way detract from the beauty of the plant.

It is of easy culture, and can be readily increased by cuttings inserted in summer after the plants have been placed out-of-doors to ripen their shoots. The young plants should be stopped when about a foot high, in order to encourage the formation of branches on which the flowers are borne. They should be grown out-of-doors during summer, and when taken inside should be given a position where they may obtain the maximum amount of sunlight. *H. Spencer.*

CULTURAL MEMORANDA.

GLORIOSA SUPERBA.

THE bulbs of these plants should at this season of the year be carefully shaken out of their old pots, and after being repotted be started into growth in a stove temperature. Gloriosas require an abundance of heat and moisture during their growing period, and for a rooting medium should be given a mixture of fibrous peat, a little loam, a small quantity of charcoal, and plenty of coarse sand. The pots should be furnished with abundant drainage material, and should be thoroughly dry, clean, and sweet before being used for the reception of the bulbs. At the end of the season moisture should be gradually reduced, and they should be kept during the winter in a resting condition in a moderate degree of warmth. These plants have a very pleasing appearance when well grown, and are effective objects when trained to wires placed at a reasonable distance from the roof of the stove or a less warm structure.

GARDENIAS.

To maintain a healthy stock of these useful, sweet-scented, evergreen shrubs, a fresh batch of plants should be raised annually by inserting cuttings of moderately firm wood either in October or at the present time. The shoots for the purpose should be inserted around the sides of small pots filled with a sweet, gritty mixture and placed in a warm propagating pit. The cuttings soon form roots, when they should be transferred singly to small pots, using a peaty soil that contains plenty of sand. If these young plants be grown on in a warm house and syringed frequently during bright weather they will grow freely and form very serviceable flowering plants during their first year. I usually stop the young growths about twice during the early part of the year to induce the formation of flowering wood and a sturdy, robust habit of growth. Two-year-old plants are very useful subjects for dwelling-room decoration, but just before they expand their flowers they are placed in a slightly cooler atmosphere. Although most gardeners affect their Gardenias a light fibrous loam, I find they prefer a rooting medium of rough peat and a small quantity of loam with a good sprinkling of sand. *H. Markham*, Wilton House Gardens.

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE PROPOSED VEGETABLE EXHIBITION.—Mr. Beckett may rest assured we shall obtain all that is good in Potatos without the aid of the National Potato Society. Leading seedsmen will not miss an opportunity of introducing a really valuable variety for the masses as a food product. There is no fear but that each seedsman will strive to introduce varieties suitable for his own neighbourhood, but is it not mere supposition that one Potato is not suitable for any but one particular neighbourhood? Was not that most popular of all varieties of Potato, Magnum Bonum, popular in all counties, and is it not also true of Up-to-Date at the present time, as well as of Windsor Castle and many other sorts? I am not sure that Potatos deteriorate so fast as to need a Potato society to replenish varieties. Experience may teach you that even one variety for use from September until the following June is sufficient for your own requirements, even if they are extensive, but for the sake of comparison you may be induced to plant a couple perhaps. From an exhibitor's point of view, three dozen sorts may be necessary, or perhaps interesting, but this is not the point at issue. Mr. Beckett knows well how difficult it is to say when a certain Leek, Onion, Cauliflower, Celery, Cucumber, Carrot, &c., bears the correct name it should have; there is such an infinitesimal difference in the various specimens that he himself would hesitate to say they were wrongly named; varieties of vegetables leave such a narrow margin for emphasis that the most clever expert might be doing an injury to a certain exhibitor were he to disqualify. Referring to the remarks of *A. D.* on p. 61, does *A. D.* really think if such an exhibition as he would like to see were provided in London that those people who such shows are intended to educate would take the smallest trouble to visit them? *A. D* cannot make such an exhibition sufficiently attractive to induce the ordinary person to step even a little out of his way to see it. You have only to remember such a show as that held in Vincent Hall but two or three years ago, and the paucity of visitors. Again, look back a little further to the Chiswick display, and note if any but vegetable enthusiasts attended either display. Even in London, where *A. D.* would have us believe so little is done, I know that every new variety of vegetable, good or bad, is to be seen as it is introduced at the R.H.S. Hall, and yet how little noted they are by the casual visitor. Of course, there is some difference between the exhibition specimen and that which is employed as food, even in the gardens of the prominent exhibitors The ordinary person cannot obtain exhibition standard produce for his daily consumption. Neither Mr. Beckett nor *A. D.* need lament the chance of the public being unaware of what is being provided for them in the vegetable world as long as we have such enthusiastic seedsmen as at present. *Onlooker.*

POINTING EXHIBITION VEGETABLES.—*A. D.* says (p. 91): "Point judging can be applied only to collections in which the number of dishes range from six upwards." Why, I ask, cannot pointing be done in a collection of four or five dishes? I have many times noted how close in point of merit collections of four dishes in cottagers' classes have often been, and from the comparison method how difficult it was to separate two and sometimes three of the competitors. The kinds of vegetables are not always the same in all the competing exhibits, some omitting even Potatos, yet staging excellent other dishes. Surely pointing under such conditions is possible. I consider equality of kinds with a maximum of seven points is not the right method of judging a collection of vegetables. The principle should be those kinds that are generally more difficult to produce should have the preference over those less difficult. Few exhibitors will place Runner Beans on the same standard of points as Carrots. Yet some judges do this. While generally agreeing with the scheme of points allowed by *A. D* for a collection of twelve dishes, I do not think Potatos can be easily grown under all conditions. If the soil is unsuitable the tubers cannot be produced in such a satisfactory state as where it is fitted better for their growth in shapely tuber formation, free from excrescences and irregularities in shape. Again, I think Cauliflowers should have a higher range of points given them than Runner Beans. Marrows, I think, are only entitled to four points on the score of easy production. I agree that Cucumbers are not deserving of the maximum number of points, even allowing a little on the score of difficulty of production. This latter consideration is outweighed by their small edible value as a vegetable. I would place the twelve vegetables thus: Celery, Leeks, Onions, and Carrots, seven points; Peas, Cauliflowers, Potatos, and Tomatos, six points; Runner Beans and Cucumbers, five points; Beet and Marrows, four points. *E. Molyneux.*

JUDGING VEGETABLES BY POINTS.—I would remind *Hortus* that there is no value in the present system of pointing, and *D.* says, p. 30, "It does not matter also whether vegetables in collections are judged by points or without points." One often sees the maximum number of points given to certain dishes; is this wise? For one often sees better dishes than those that have been already awarded the maximum number of points similarly awarded, and it is perplexing to *Hortus* and other experienced growers to know what is the best quality and highest standard of any kind of vegetable. *D.* says, "When show committees require that collections be judged by points and fix the scale of points for each dish or kind, the judges have to do as instructed, and when such is the case the points are published on the respective collections." This is not always the case, and, for instance, I may mention the Edinburgh International Collections of Vegetables (1905), which, according to the schedule, were to be judged by points, but these points were not published, and a large amount of interest was lost by their omission. Referring to the quality of the various kinds, p. 91, when six distinct kinds of vegetables are staged, experienced judges should use their discretion as to whether a brace of Marrows exhibited, say, in May, should not receive the same number of points as Tomatos, and, again, if the Marrows were staged in the place of the Tomatos in July, to award them the maximum number of points. As *A. D.* suggests, there is still room for improvements. *Curious.*

LEAF CURL OF THE PEACH AND NECTARINE.—I read with much interest Mr. W. Fyfe's remarks on this subject, pp. 100 and 101. I have grown Peaches and Nectarines extensively on open walls in an adjoining county (Wiltshire) to that in which Lockinge Gardens are situated, and although I have been troubled with curled or blistered leaves more or less during the months of April and May, I have never sustained any loss either in the vitality or vigour of the trees or in the quantity and quality of the crop. I suppose the climatic conditions generally in Wiltshire are more favourable for the culture of Peaches out-of-doors than those prevailing in Berkshire. As soon as the leaves began to curl in the slightest degree I examined the trees daily and picked off all affected leaves and burnt them. I never allowed the foliage to become badly injured before taking this action, with the result that the trees in a short time showed no evidence whatever of having been affected with curled or blistered leaves. It is generally believed that the blistering of the leaves is caused by a spell of cold following a short period of warm, genial weather. This causes the growth to be checked, and deformity is the result. The only remedy that I know is the hand-picking recommended above. Only the worst leaves should be first pinched off trees that have been allowed to become badly affected, removing the remainder as soon as a favourable change in the weather induces fresh, healthy foliage to push forth. If aphides are allowed to effect a lodgement on the young leaves of Peach and Nectarine trees in the spring, either under glass or on the open walls, they will soon cause the foliage to curl. Fumigations of tobacco paper or XL-All vaporising compound in the evening will rid the trees under glass of the aphis; the trees should be syringed the following morning with clean water Trees growing against open walls should be syringed with a solution of tobacco juice used in the proportion of one quart to four gallons of water, this being applied after the sun has left the trees in the afternoon. One application will prove sufficient for the year, as it not only destroys the insects then on the leaves, but also renders them distasteful to future attacks. *H. W. Ward.*

———I read with interest Mr. Fyfe's letter, p. 101, with reference to the Peach blister. I also have tried many remedies, but have found no effectual cure for the disease. I am of the opinion that the blister is caused by very cold winds, which chill the leaf in its young stage, and I think this is proved by Mr. Fyfe's statement that after erecting the Peach case over the same trees they were not attacked with the malady. There is a Peach wall under my care here with a good wide border and upon part of this border I planted last year Early Peas, and the Peach trees opposite the rows of Peas did not have a leaf injured by blister, but higher up the border one tree was practically killed and the others badly injured. The part of the wall at the particular end where the trees were not affected is much higher and so it affords a better shelter. *A. Gooding.*

A SUSSEX WASTE.—Living, as I do, on the borders of the Ashdown Forest, and taking the keenest interest in all that appertains to forestry, it is impossible to pass over Mr. Simpson's article on this subject without an expression of regret that the writer should have put such a misleading picture before your readers. The article is typical of much that is written, with every good intention no doubt, but is calculated to create a vast amount of misunderstanding and to do a great deal of harm to a cause which many of us have at heart. From a forestry, and also from an economic point of view, we should like to see much of the so-called "waste land" planted, but having regard to the rights of the commoners and the extreme difficulty of enclosing any piece of common land since the passing of the Law of Commons Amendment Act, 1893, it is idle to talk of planting up the open spaces to which he refers. It is impossible within the limits of a letter to deal with the complicated question of commons and commonable lands, or with the recent Acts of which Mr. Simpson is apparently entirely ignorant. And it is useless for me to argue the question of the fertility of the land when he is under the impression that it is clay, whereas it is practically all sand, and is known geologically as Ashdown sand. It is not "good land that has been allowed to become waste"; it does not belong "to anybody"; it is not "mostly first-class agricultural land"; and what the writer has been told about the "local laws" is not a fact, and if it were it would be impossible to preserve the trees without fencing, and so excluding the commoners who need the land for grazing purposes and for cutting litter. *Leslie S. Wood, East Grinstead.*

WINTER PARSLEY.—In the issue for February 22, *P. P. R.* wrote regarding a continued supply of Parsley during winter months. At the latter end of July or early in August I prepare, say, 50 6-inch pots, using for the potting compost good loam, cow manure (passed through a ½-inch sieve), a little leaf-soil, a sprinkling of bone meal, and a quantity of old mortar rubble. I fill the pots fairly full with the compost, and after making the soil firm, sow a pinch of seed in each pot. The pots are placed on an ash bottom in a cold frame. When the seed has germinated I thin out the seedlings to four plants in each pot. I keep them in the cold frame, but when the weather is fine and heavy rains are not expected the lights are removed entirely. The pots are plunged in ashes up to their rims, and when the plants have made some good foliage and the pots are fairly filled with roots they are given applications of liquid manure about once each week, also a good sprinkling of soot occasionally. If the plants are kept in the frame, and the lights be covered with mats in frosty weather, a good supply of Parsley can be thus maintained. If the supply runs short a few pots can be put in an early vinery or Peach-house, and the plants will soon respond to a little forcing. This method served me well three years ago, when frosts and fogs destroyed all outside Parsley. *H. R., Kent.*

SICK PAY FOR GARDENERS.—The question of the liability of the employer to pay wages and provide medical attendance for the employé when sick is frequently discussed in the Press. Most industries now have their union which, among other advantages, makes provision for the sickness of its members. Gardeners, however, have not yet got so far as to form any combination for this purpose, and although many join working men's clubs or benefit societies that provide help during sickness, a great many, particularly the young men, rather than pay a small subscription prefer to risk it, feeling that they will not need such help, and that they have a better use for their small earnings. Consequently, when they fall sick, they have to depend upon charity in some form or, failing that, they have a bad time. In Germany, there is a universal system of sick pay for workmen which has been in practice for some years, and although it is not perfect, it is at any rate something certain as a standby. The gardener, whether he be employed in a nursery, a private garden, or a Government establishment, must put by a certain sum monthly into a kind of Government insurance fund. This averages about 4½d. per week, and is generally deducted from the wages of the employe monthly. Should he fall sick, from whatever cause, whether due to the nature of his employment or not, he is entitled to medical attendance, and a daily allowance equal to his monthly subscription. There is a separate scale of charges for head gardeners, foremen and the like, who subscribe about 3s. per month and receive that amount per day while sick. This arrangement is not optional but is enforced by law. Even in cases where other provision for sick pay is made the workmen must subscribe to the State fund, and in return he receives the usual help, whether he needs it or not. The State help is given for a period of six months if required. After that time, should the person still be ill, he continues to receive a reduced amount, but the cases of illness that extend over periods of more than half a year are few and far between. Medical attendance includes dentistry. Artificial teeth are also provided at a trifling cost. While it cannot be urged that the system here described is a perfect one, it has much to recommend it. There is no savour of charity in it, although 1s. 6d. per day is not a big allowance for a sick man, it is a great deal better than nothing. To this must be added medical attendance, and in Germany the working classes are very economical. While the minimum is fixed, anyone may pay more, and as a result receive more if he prefers to. Is there any practical reason why such a system should not be introduced into the United Kingdom? Surely, it would be a great deal better than the village slate club, which is not always a very trustworthy prop, and now and again proves unable to meet the claims made upon it. *J. G. W., Berlin.*

THE HARDINESS OF GUNNERAS.—Mr Arnott's appreciation of these immense-foliaged "hardy herbaceous perennials" should induce those who hesitate under the impression that the Gunneras are only half-hardy to give them a trial. For some years I was under the impression that the larger species, G. manicata, was less hardy than the more robust-looking G. scabra, but now I am of the opinion that there is little difference between the two in this respect. Unprotected crowns of both species were unharmed by 23° of frost registered on January 3 last. The mean temperature at Pencarrow during the first 12 days of this year was not more than 30·83°; therefore these Gunneras may be considered hardy in most gardens south of the Tweed. Although the crowns do not suffer from frost, the foliage of the two species of Gunnera above named will not withstand more than 3° or 4° of frost, and after a mild winter the first leaves thrown up in the spring are often killed by frosts before they have had time to unfold. As noted in these columns last year, a Gunnera sent here by Mr. H. J. Elwes, which was raised from seed collected by him in Chili, has proved to be more hardy in this respect than the two commoner species. Whilst seedlings of G. scabra spring up around the plants, I have not yet seen any seedlings of G. manicata. To produce the enormous leaves mentioned by Mr. Arnott it is necessary to plant the Gunneras in a moist, rich soil. An ideal spot is one by the side of a stream or pond, but not in boggy ground. From the time the leaves first appear until they are fully developed, liberal dressings of nitrate of soda, followed by copious waterings if the weather is dry, given fortnightly, will materially increase the size of the leaves. *A. C. Bartlett, Pencarrow Gardens, North Cornwall.*

THE FLORISTS' ART.—*F. M.*, on p. 439, appears to have quickly forgotten the special exhibition held in the R.H.S. Hall some three years ago by the Council of the Royal Horticultural Society, at which medals were offered for all conceivable classes and persons, but which ended in utter failure as far as the result was concerned, and this for several reasons. In the first place, the prizes were of the wrong kind. Not one young lady in fifty would value even a gold, much less a silver, medal as a prize for table decorations. The Council of the R.H.S. may think much of these awards, but if they—the management—were aware of the scorn some ladies display at the offer of such prizes, they would be likely, if they had any desire to encourage this phase of horticulture, to offer prizes of another description. I do not say in cash, but something at least useful. No one will say that a medal is in any way useful to a lady! Few persons who saw that show agreed with many of the awards, and fewer still saw anything to admire in it as an educational display, mainly owing, in my opinion, to the quality of the prizes. *F. M.* agrees that some of the classes should be "open," thereby enabling florists by profession to enter and thus to give object-lessons in an art in which they are admittedly efficient—in one point especially—that of making an effective display with a minimum of material; this knowledge is often sadly lacking in the ordinary gardener, who requires much material to obtain what is required in the way of effect. At Cardiff where, in July, substantial prizes are offered for table decorations, there is always an interesting display, because in the "open" class, men of reputation display of their best, and this is really an object-lesson to the amateur how to utilise silver, glass, fruit, and flowers. I think Chrysanthemum exhibitions display the most crude taste of any in the whole range of classes set apart for the public in table decoration. Exhibitors in the majority of instances go to one of the two extremes of lightness or heaviness. The larger the tables provided, the worse are the results obtained; they seem to load the vases far too heavily, or else they furnish them much too thinly to give a pleasing effect. Many exhibitors, too, arrange the colours crudely. This, however, I think, is often the fault of schedule makers. If the conditions were more precisely set out as to daylight versus artificial light, a different scheme of colouring would no doubt be employed. Many exhibitors employ flowers that are altogether unsuitable—some are "lumpy" and heavy; others again, in avoiding this defect, use those not good enough in quality. Small, quarter-sized, undeveloped buds are of little use in arrangement, yet we too often see vases on a table filled with such material. Every receptacle on a table intended for flowers should be a specimen in itself, and should be so arranged as to bear individual inspection, yet the reverse is much too frequent. *E. M.*

STRAWBERRIES.—Looking over some old numbers of the *Gardeners' Chronicle*, and some memoranda of my own, I find that the following varieties of Strawberries were once in cultivation. Market growers do not keep many varieties. The Kentish growers 30 years or so ago in the neighbourhood of Farnborough confined themselves to British Queen, President, and Sir Joseph Paxton. One grower made a fortune from the first-named variety, and he built a large hotel and called it the British Queen. Most of the Strawberries were grown on ground that had been woodland. In addition to the varieties named, the following sorts have been grown here:—Keen's Seedling, La Grosse Sucrée, Vicomtesse Hericart de Thury, Noble, Waterloo, Kitley's Goliath, Sir C. Napier, Auguste Nicaise, Loxford Hall, James Veitch, and Elton Pine. Now we only grow Royal Sovereign, Fillbasket, and Givon's Late Prolific. *W. P. K., Preston.*

THE LATE WILLIAM COLEMAN.—With the passing from life of William Coleman we have lost one of the great gardener fruit-growers and exhibitors of the nineteenth century. He made Eastnor Castle a household word in horticultural circles, and at exhibitions upheld the art of fruit culture to a high position. Not only was the late Mr. Coleman a skilful cultivator, but he was also a good writer. Young gardeners found in him an able and reliable mentor. Long as Mr. Coleman has retired from the post of gardener at Eastnor, his earlier writings and his great reputation served well to keep his memory green. It was, perhaps, amongst the incongruities of life that, eminent as he was a gardener, and especially as a fruitist, he never received the Victoria Medal of Honour. Nevertheless he has honoured gardening by his ability, his fidelity, integrity, and high-mindedness. Young gardeners to-day may well ask us to the methods which made Eastnor so famous as a great fruit garden and if they will strive to emulate William Coleman's efforts, both in the garden and in competitions, we may yet see fruit competitions keeping up their high excellence and interest. *Septuagenarian.*

THE WEATHER.

THE FOLLOWING SUMMARY RECORD of the weather throughout the British Islands, for the week ending February 22, is furnished from the Meteorological Office:—

GENERAL OBSERVATIONS.

The *weather* was generally very changeable, with much cloud and occasional falls of rain. The unsettled condition culminated on Saturday in an extremely rough and showery state over the whole Kingdom, with violent hail and rain squalls in many localities, and thunderstorms over a large part of Great Britain. A parhelion was observed at Norwich at 10 a.m. on the 20th.

The *temperature* was again above the normal, the excess ranging from 2·7° in Scotland N. to between 4° and 5° over the Kingdom as a whole, and to slightly more than 6° in the Midland Counties. The highest of the maxima occurred early in the week in a few localities, and generally they were recorded towards its close. They varied from 55° or 54° in most districts to 52° in Scotland W. and Ireland N. The lowest of the minima, which were mostly registered on the 16th or 17th, varied from 25° in Scotland E., to 36° in Ireland N., and to 39° in the Channel Islands. The lowest minima recorded on the grass were 19° at Crathes, 21° at Balmoral, and 23° at Cockle Park, Rauceby and Cambridge.

The *mean temperature of the sea*. At all the sea temperature stations the water was warmer than during the corresponding week of last year, the difference amounting to more than 2° in several places, and to 3·3° at Penzance Bay. The actual values ranged from 47.2° at Seaheld and 47° at Newquay and Ballyglass to 39.8° at the Shipwash Lightship.

The *rainfall* was more than the normal in all districts except Ireland S., the excess being rather large over the Kingdom generally.

The *bright sunshine* was deficient except in Scotland W. The percentage of the possible duration ranged from 27 in Scotland E. and 25 in Scotland W. to no more than 11 in England E. and S.W. and Ireland S., and to only 8 in the English Channel.

THE WEATHER IN WEST HERTS.

Week ending February 26.

Frequent squalls of wind and rain. For three weeks there has not been a single unseasonably cold day, and but one cold night. On the warmest day during the past week the temperature in the thermometer screen rose to 51°, and on the coldest night the exposed thermometer registered only 5° of frost. The ground, owing to the lack of sunshine, is colder than it was a week ago, and is now at about an average temperature at 1 foot deep, and 1° warmer than is seasonable at 2 feet deep. Rain has fallen on all but two of the last 11 days, but to the total depth of not much more than ¼ inch. Hail fell on two days. Small amounts of rainwater are now coming down through each of the percolation gauges. This has been a very dull week. In fact, the sun shone on an average for less than an hour a day, which is less than half the mean duration of bright sunshine for February. On two days no sunshine at all was recorded, and on three others the sun shone for less than an hour. The winds have been, as a rule, high, and in the windiest hour the mean velocity amounted to 26 miles direction west. This is the highest wind recorded here since December 14 last year, on the same day, the 22 of inst., for the six hours ending 10 p.m. the average velocity was 23 miles. The mean amount of moisture in the air at 3 p.m. exceeded a seasonable quantity for that hour by seven per cent. A selected bush of the Wild Hazel first showed a female flower on the 19th, which is one day later than its average date for the previous 17 years, but a week earlier than last year. *T. W., Berkhamsted, February 26, 1908.*

MARKETS.

COVENT GARDEN, February 26.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

Cut Flowers, &c.: Average Wholesale Prices.

REMARKS. The consignments of Apples from Nova Scotia and Canada are much smaller and prices are firmer. The demand for Oranges and Grape Fruit remains good owing to these fruits being recommended to the public for consumption during the prevailing epidemic of influenza. English Grapes continue to sell freely. Bananas are cheaper but best coloured bunches are in demand. The trade in Cauliflowers is not so brisk as it has been recently. Supplies of Cape Nectarines are practically finished, the few boxes that have arrived this week have realised high prices. Peaches from the same Colony, labelled "Catalina," are of fine quality and highly-coloured. They sold readily at from 5s. to 6s. per dozen.—*T. L., Covent Garden, Wednesday, February 26, 1908.*

Potatos.

Kents: Up-to-Date, 100s. to 105s. per ton; British Queen, 90s. to 100s. per ton; Scottish Triumph, 95s. to 100s. per ton. **Lincolns:** Up-to-Date, 95s. to 110s. per ton; Up-to-Date (Blackland), 85s. to 90s. per ton: British Queen, 90s. to 100s, per ton; British Queen (Blackland), 80s. to 90s. per ton; Maincrops 100s. to 105s. per ton; Sir Jno. Llewelyn, 85s. to 100s. per ton; Sir Jno. Llewelyn (Blackland), 80s. to 85s. per ton; Royal Kidney, 90s. to 95s. per ton; Royal Kidney (Blackland), 80s. to 85s. per ton; Evergood, 85s. to 90s. per ton; Evergood (Blackland), 75s. to 85s. per ton; **Dunbars:** Up-to-Date (red soil), 110s. to 115s. per ton; Maincrop (red soil), 115s. to 120s. per ton. **Scotch:** Up-to-Date (grey soil), 90s. to 100s. per ton; Maincrop (grey soil), 100s. to 105s. per ton. **German:** Up-to-Date Bonum, 4s. 3d. to 4s. 6d. per bag; Magnum, 4s. to 4s. 3d. per bag; Imperator, 3s. 6d. to 4s. per bag. **Belgium:** Kidneys, 3s. 9d. to 4s. per bag. **Dutch:** Up-to-Date, 4s. per bag; Magnum Bonum, 3s. 9d. to 4s. per bag; Imperator, 3s. 3d. to 3s. 6d. per bag. Trade is still very quiet. Supplies are plentiful. *E. J. Newborn, Covent Garden and St. Pancras, February 26, 1908.*

COVENT GARDEN FLOWER MARKET.

There has not been much increase in trade during the past week. The imports of cut flowers have been large, and this morning the arrivals were heavier than usual. Among imported pot plants supplies of Palms from Belgium have fallen off, but Aspidistras have been received in large quantities.

Cut Flowers.

Daffodils are now the most prominent feature, and prices are very uncertain, the very finest blooms of Emperor, Victoria, and Golden Spur are sold at about 8s. per dozen bunches. The Paper-white Narcissus is now nearly over, and those seen are mostly far advanced and not of much value. N. Soleil d'Or from the Scilly Islands is abundant and good; White Pearl, Gloriosa, and others are over plentiful. Tulips are of good quality. On Mr. Holdrup's stands I noted Cramoise Brilliant and Austria, the finest of the single crimsons. Imperator is a very fine double crimson variety. Lucretia, pink; Murillo, blush, and Couronne d'Or, yellow, are other fine double varieties in the market. Mr. H. Williams grows large quantities of these flowers, and markets most of them as growing on the bulb. Mr. Pratley also has very good Tulips in flower as plants in boxes. Roses of better quality are now seen. The variety Richmond from Mr. Curry is very fine; blooms on long stems are realising 10s. per dozen. Caroline Testout is now very fine, and there are also some of the variety Mrs. J. Laign on long stems. Niphetos is the best white variety in the market. Carnations in all colours, except yellow, are abundant. Fiancee is a favourite kind with the florists. White Perfection is one of the best, the blooms remaining fresh for a considerable time. Winsor is also much appreciated. Britannia and Robt. Craig are the leading scarlet varieties. Mrs. T. W. Lawson remains a favourite; the best "crimsons" are President Roosevelt and Harry Fenn. A few good "Malmaisons" are seen. Mr. Burnett's Marmion is a great favourite, and has made high prices. Callas are more abundant and their prices have fallen. Lilium longiflorum varies: choice flowers of this species are valuable. Blooms of L. lancifolium rubrum are now of a good colour. A few examples of L. auratum are seen, but the flowers are rather small. Violets from English growers are good. Princess of Wales and La France are favourite varieties. Lily-of-the-Valley has depreciated in value. Eucharis is now plentiful. Other choice flowers seen include Stephanotis, Pancratiums, and English-grown Orange Blossoms. Orchid blooms are plentiful, and Cattleyas are cheaper than they were a week or two ago.

Pot Plants.

Indian Azaleas are still over plentiful. Apollo is one of the finest of the scarlet varieties. Vervaneana is another good kind; the flowers are usually striped, but some plants produce scarlet flowers only. Niobe is one of the best double white kinds, and Professor Walters is of a beautiful pink colour. Boronia megastigma is now coming from Mr. Sweet's nursery, also Acacia Drummondi. Edna fastigiata is very pretty. Primula obconica of a good strain is sent by Messrs. H. B. May and Sons. Pot Mignonette was noted this morning, but it is not yet of the best quality. Pelargonium F. V. Raspail in well-flowered plants were noted on Messrs. Butler Bros.' stands. Hyacinths, Daffodils, Spiræas, and Lily-of-the-Valley, in pots and in boxes, are all good. Ferns with fresh spring fronds are now plentiful. Palms and other foliage plants are arriving in large quantities. *A. H., Covent Garden, February 26, 1908.*

DEBATING SOCIETIES.

SALISBURY AND DISTRICT GARDENERS'.—At the last meeting of the above society Mr. J. Challis, V.M.H., read a paper entitled "The Theory and Practice of Horticulture." The lecturer impressed upon the younger members the necessity of thought in conjunction with acting. He also gave them a simple code of rules by which they might safely be guided. It proved a highly educative paper and coming from one of the oldest members of the society was very heartily received. Mr. S. Tucker, vice-chairman, presided.

PANGBOURNE & DISTRICT GARDENERS'.—At the meeting of this association on February 5, Mr. F. W. Exler, The Gardens, Foxhill, Reading, read a paper on "Melons and their Culture." The paper gave rise to a good discussion, in the course of which much information was gained by the members. *E. W. D.*

BATH AND DISTRICT GARDENERS'.—There was an exceptional attendance at the meeting of this association held on February 13. The president (Alderman W. F. Gould) occupied the chair. Mr. T. Challis, gardener to the Earl of Pembroke, read a paper on the effects of climatic conditions on horticulture and the importance of the proper use of air, heat, and moisture for the successful growth of fruit and plants in the hothouse. The president, in thanking Mr. Challis for his excellent paper, spoke of his connection with Bath as a judge at its floral exhibitions for the past 40 years. Several new members were elected.

CROYDON & DISTRICT HORTICULTURAL.—At the meeting of this association held on Tuesday, February 18, Mr. H. Withers delivered a lecture on the life history of some of the most important insects found in the garden and field. Often, the lecturer explained, little friends in the insect world are destroyed through ignorance of their usefulness. Amongst those to be encouraged are the ladybird, whose larvæ feeds upon aphides, the golden-eyed fly, ants, and many of the Ichneumon flies. The lecturer remarked how interesting it was to watch the larvæ of the lacewing fly at work holding the aphis with its jaws and sucking the juices from the body. Unlike animals, insects had no lungs, but breathed through long tubes called trachea, running through the body and limbs, and in many instances ways had to be found for stopping these tubes, whilst other species were destroyed by poisonous juices placed in their haunts.

REDHILL, REIGATE AND DISTRICT GARDENERS'.—At the meeting of this association held on February 18, Mr. H. G. Cox, secretary of the Reading Gardeners' Association, delivered a lecture on "Primulas." The lecture was illustrated by means of about 60 lantern slides, many of them being coloured by hand. Mr. Cox had several specimens of Primulas on view, and gave many useful hints as to their culture. Ten new members were elected.

———At a special meeting held on Saturday, February 22, under the presidency of Mr. Bound, Mr. N. E. Brown, of Kew, gave a lecture on the proper pronunciation of certain names of plants commonly used by gardeners. Aided by a blackboard, Mr. Brown began his lecture by explaining the use of Latin and Greek roots, and the difference of the long and short vowels.

CHELMSFORD & DISTRICT GARDENERS'.—On Friday, February 14, Miss Philbrick, of The Cedars, Halstead, gave a lecture on "The Daffodil." The lecture-room was filled with a most appreciative audience, and the lecturer's treatment of her subject was enthusiastically applauded.

———On the 21st inst., members of the association numbering about 100 listened to a lecture on "Mendel's Law of Inheritance," delivered by Mr. F. J. Chittenden, director of the R.H.S. Laboratories, Wisley, and formerly lecturer in biology at the County Laboratories, Chelmsford. Members had long looked forward to this lecture, and a hearty welcome was given to the lecturer.

GUILDFORD AND DISTRICT GARDENERS'.—At the fortnightly meeting of this association, held on Tuesday, February 18, 57 members assembled, under the presidency of Mr. W. Hogsden, to hear a lecture delivered by Mr. W. Seaman, representative of the Redhill, Reigate and District Gardeners' Association, on "Vegetables for Exhibition." Mr. Seaman strongly urged the importance of deep cultivation and recommended that in order to produce the best results the ground for vegetable culture should be well trenched during the late autumn and winter. *J. G.*

CARDIFF GARDENERS'.—The fortnightly meeting of this society took place on Tuesday, February 18, when Mr. R. T. Went read a paper on "Forestry." The lecturer gave some very interesting and practical information upon the subject of sowing the seeds of various trees, preparing the ground as a seed-bed, the selection of seeds, sowing, transplanting, &c. The lecturer stated that more interest was being taken each year in forestry.

SCHEDULES RECEIVED.

Newcastle-upon-Tyne Summer Flower Show to be held on July 1, 2, and 3, 1908, in conjunction with the Royal Agricultural Society's exhibition in that city.

Croydon Horticultural Society's 41st summer show, to be held in a meadow adjoining Haling Park, Brighton Road, Croydon, on Wednesday, July 8, 1908.

Canterbury and Kent Rose Society.—The 30th annual show of this Society will be held on Tuesday, June 30. The prizes include a Challenge Cup of the value of nine guineas offered in a class open to nurserymen.

Women's Agricultural and Horticultural International Union's Show, to be held in the Royal Botanic Society's Gardens, Regent's Park, on Wednesday, July 15, 1908.

Obituary.

WILLIAM COLEMAN.—The news of the death of this famous old gardener reached us just after our last issue was closed for the press. He passed away on Thursday, February 20, from heart failure, at the age of 81 years. His decease was very sudden, for about two hours previously he was engaged in his private garden. The late Mr. Coleman, although perhaps not so well known to the younger generation of gardeners, ranks high amongst horticulturists of the past century, and as far back as 1875 his portrait and an account of his life was published in the *Gardeners' Chronicle* as one of a series of articles on famous British gardeners. He was born in 1827 at Rolleston, in the eastern part of the county of Leicester, his father being gardener and manager on the estate at Rolleston for more than half a century. Leaving home for the purpose of acquiring experience, his first situation was at Cole Orton, and in 1846 he entered the service of Lord Howden at Grimston Park, Tadcaster. He also served at Pont-y-Pool Park, at that time one of the finest gardens in the county of Monmouthshire for the forcing of fruits and plants. Deceased also served at Crewe Hall, Cheshire, in the capacity of foreman, a place noted for its excellency in the culture of Pineapples and vegetables. After filling other situations, including employment at the Royal Exotic Nurseries, Chelsea, Mr. Coleman was appointed to the management of Eastnor Castle Gardens, entering on his duties there on May 1, 1860. The memorable winter of 1860-61 destroyed many of the choicest specimens of trees and plants at Eastnor, and Mr. Coleman immediately set about replacing them with the rich treasures sent home from Japan by Messrs. Veitch and Fortune. The glasshouses were all rebuilt under his supervision, and he arranged the planting of the pleasure grounds, in which he showed excellent judgment. After about 30 years of successful management of the gardens, Mr. Coleman was appointed by Lady Henry Somerset agent for the Eastnor estates, which post he well filled for about 12 years. Through failing sight he retired after 42 years of faithful service, which was greatly appreciated by his noble employers. Although relieved of his arduous duties as agent, Mr. Coleman was always active, and spent pleasant days in his beautiful little garden that contained rare specimens of Alpine and herbaceous plants. A noble, upright man of sound judgment, which was much sought after and appreciated, he will be sorely missed by those who knew him best. The funeral took place on Monday, the 24th inst., at Eastnor, and was attended by a very large number of friends. The deceased was held in the very highest esteem in that quiet country village, to which signs of mourning were everywhere apparent. It was the unanimous opinion of those present at these last rites that British horticulture had lost one of her best representatives, for no one had ever done more, both by hard work and by humorous pen, or were more successful as a gardener and administrator of horticulture.

THE LATE WILLIAM COLEMAN.

THE MARQUIS DE WAVRIN.—We regret to announce the death on the 24th inst. of the Marquis de Wavrin, Chateau de Rousele, Ghent, Belgium, one of the most enthusiastic and successful of Belgian orchidists. The late Marquis was a lover of Orchids, both species and hybrids, and was a successful raiser of good novelties, some of which he has exhibited at the meetings of the Royal Horticultural Society, as, for instance, the two forms of Cattleya Triane shown on the 11th inst.

ENQUIRIES AND REPLIES.

SEA SAND FOR A BOWLING GREEN.—In reply to Mr. W. Davis respecting sea sand for bowling greens, I have for many years past used it as a spring dressing, and the results have been very satisfactory. Some of the finest bowling greens and lawns in the North have been made so by the discreet use of sea sand, but if, as Mr. Davis states, he has put tons of sea sand on a bowling green of ordinary size in the course of two years, I do not wonder at his grass turning yellow. Sea sand must be applied at the right time and with discretion. My practice is to obtain a waggon-load every spring, in time to arrive about March. This is put on the turf immediately we receive it at the rate of a spadeful to the square yard, for if sea sand is allowed to remain in the open for any considerable length of time, its stimulating properties are washed away. Any sand that is unused in spring is kept till about September, when it is used for mixing with the soil in frames, &c. Sea sand, besides being a first-class spring dressing for grass, has a wonderful effect in destroying worms, for by its use these creatures are completely eradicated from the turf in the course of a few years. To maintain a lawn in a good condition, some other fertiliser should be applied during the late autumn or winter. It must be remembered that the grass of a lawn will turn yellow through lack of effective drainage more than from any other cause. *Thos. Francis, 31, Turton Road, Bromley Cross, near Bolton, Lancs.*

GARDENING APPOINTMENTS.

MR. KRIMBIEGEL has been appointed Superintendent of Mysore State Gardens, Bangalore, India.

MR. G. CHARLTON, for 5¼ years General Foreman in Skelton Castle Gardens, Yorkshire, as Superintendent of the Kelvinside Fruit Farm, Dundee, Natal, South Africa. Mr. CHARLTON is leaving England in April to take up his new duties. (Thanks for 1s. which has been placed in the R.G.O.F. box.)

MR. G. L. EVANS, for more than 8 years Gardener to the late Major CORBETT WINDER, as Gardener to Sir H. M. JACKSON, Bart., Llantilio Court, Abergavenny.

MR. F. HONEYMAN, for the past 3 years at St. Marnocks, Dublin, and formerly an Inside Journeyman at Hallyburton, Coupar Angus, N.B., as Gardener to Lord CLARINA, Elm Park, Clarina, Limerick.

MR. J. COOK, formerly at Hallyburton, Coupar Angus, and until recently Outdoor Foreman at Stratton Park, Micheldever, as Gardener to Mrs. HORHOUSE, Hadspen House, Castle Cary, Somerset.

MR. A. HALL, employed for the past 2 years and 8 months at Oakley Hall Gardens, Basingstoke, as Gardener to L. PHILLIPS, Esq., Deane House, near Whitchurch, Hants.

MR. A. J. WELLS, for the past 3 years Foreman, and for some time in charge of the Gardens, Forde Abbey, Chard, as Gardener to Her Grace the Duchess of WELLINGTON, at Ewhurst Park, near Basingstoke, Hants. (Thanks for your contribution to the R.G.O.F. box.)

MR. JAS. WADHAM, late of Sneyd Park House, Bristol, and previously 12½ years at Holmbury, Dorking, Surrey, as Gardener and Bailiff to Sir WILLIAM TRELOAR'S Cripples' Home and College, Alton, Hants.

MR. F. A. JOHNSON, for the past 2 years Gardener to Her Grace the Duchess of WELLINGTON, Ewhurst Park, as Gardener to A. C. DRUMMOND, Esq., Cadland, Southampton.

MR. R. STANARD, for 2½ years Gardener at Loseley Park, Guildford, as Gardener to Countess COWPER, Panshanger, Hertford.

MR. ALEXANDER METHVEN, for the past 2 years Foreman in Bothwell Castle Gardens, Bothwell, as Gardener to Mrs. DOUGLASS JACKSON, Milhigg House, Galston, Ayrshire, N.B.

Answers to Correspondents

ACETYLENE GAS LIME: *E. J. H.* This material can be used as a manure to supply the constituent lime, but it should be placed in a heap exposed to the influence of the atmosphere for a month or two before being used. It is more suitable for heavy clay lands than for the lighter and more loamy soils, and it is also more adapted for coarse-growing plants such as members of the Cabbage family than for Roses, or flowers generally. Another point to be observed is never to apply acetylene gas lime to land planted with Potatos, as it is apt to impart a very unpleasant flavour to the tubers. For Roses growing in a lime-deficient soil, use ordinary quicklime mixed with sulphate of magnesia (Epsom Salts), four parts of lime to one part of magnesia and apply 6 ozs. of the mixture per square yard any time during the month of March. In using acetylene gas lime for the coarser varieties of plants on land deficient in lime, 8 ozs. per square yard may be trenched in some time previous to planting.

BLUE SWEET PEA: *S. B. Dicks.* In the review of *Sweet Peas and their Cultivation* on p. 98, our reviewer stated that blue Sweet Peas were in existence in 1838, and that Mrs. London noted them in that year. The following passage occurs on p. 130 in *The Ladies' Flower Garden of Ornamental Annuals*, published in 1840:—". . . the blue, which has the wing and keel of a pale blue and the standard of dark bluish-purple."

BOX DISEASED: *P.* The Box leaves are affected with the Box rust Puccinia buxi. The best plan to eradicate the fungus is to syringe the bushes with Bordeaux mixture.

CHRYSANTHEMUMS: *Fossy.* All the varieties in your list belong to the Japanese section, with the exception of Mrs. C. Rogers, which is an incurved variety. Several of them, however, are quite out of date, and others in the list, though useful for greenhouse decoration, are of little value as exhibition varieties.

EUCHARIS BULBS: *C. E.* We do not consider the bulbs you send to be of first-class size, but there does not appear to be any disease in them.

GARDENER'S NOTICE: *J. H.* The length of notice you are entitled to is purely a question of custom. If you are paid fortnightly, you would probably be held entitled to a fortnight's notice, as, although this fact is not conclusive evidence on the point, yet, in the absence of any local custom or special agreement as to notice, the presumption of law is that the parties have decided for themselves what is "reasonable notice" by their agreement as to payment of wages, and that reasonable notice is the interval between two payments. In the case of domestic servants, wages are calculated at so much a year, and whatever the intervals between the payments, there is a well-established custom of a month's notice on either side. It has been decided that a head gardener, paid at a yearly rate, is entitled to a month's notice. In your own case, as a foreman gardener paid fortnightly, you should claim a fortnight's notice. —*H. M.* A gardener, like a domestic servant, is entitled to be paid his wages during temporary disablement by illness. If the master wishes to terminate his liability to continue to pay wages to a man who is unable to work, he must give notice of dismissal. In the absence of any special agreement, the length of notice to be given depends on custom, and, under the circumstances which you state, you would probably be held entitled to a month's notice, especially as you are paid monthly, though the latter fact is not conclusive evidence on the point.

GRUBS IN PEAT: *H. P.* The objects found in the peat in which your Calanthe Veitchii was growing are the egg capsules of one of the cockroaches. The females do not lay their eggs separately as most insects do, but several eggs (about 16) are laid together in a case in two rows of chambers. This case has a longitudinal slit, the edges of which are compressed together, and cemented, so that nothing can enter. When the young are hatched they discharge a fluid from their mouths which dissolves the cement, and the little creatures are then able to make their way out. You should destroy every egg case that you can find, for cockroaches are very destructive creatures to Orchids and other plants, as they gnaw the roots and young shoots. The parent insects may be killed by the same means as is adopted for exterminating cockroaches in dwelling houses.

LILY OF THE VALLEY FAILING. *Puzzled.* The Lily crowns are not suffering from disease. The growths appear to have been killed by frost.

MAPLE WITH UPRIGHT FLOWERS: *M. M. N.* The finest of the erect-racemed Maples is Acer macrophyllum, a North American species. The flowers of the Norway Maple are also borne on somewhat erect clusters. Of smaller species (the two preceding are large trees) with erect racemes A. tataricum and A. spicatum are to be recommended.

MARKET CHRYSANTHEMUMS IN POTS: *A. R. B.* The following varieties are selected from among the best seen in the market during the past season. The season of flowering varies considerably, according to the treatment afforded the plants. Madame Desgranges was one of the earliest seen in Covent Garden in the autumn of 1906, but last season the best plants of it were not marketed until October. All the various sports from Madame Marie Masse are valuable for early flowering, Horace Martin and Ralph Curtis being the most useful. Market White forms a good pot plant for early blooming, as do Lady Fitzwigram, Harvest Home, Goacher's Crimson (the two last-named, unless grown under careful treatment, lose their foliage), Geo. Wermig, and Nivette are all to be recommended. Carnie is one of the best of the early yellow varieties. Maxim (chestnut-red), Perle Rose (a pretty shade of pink), and Souvenir de Petit Ami are also worthy of culture. Of the later or second early varieties may be mentioned Mrs. Wingfield, Miss B. Miller, La Pacatole, Boule de Neige, Kathleen Thompson, Market Red, W. Holmes, Caprice du Printemps, Moneymaker, Soleil d'Octobre, Ivory, Pink Ivory (known in the market as White Star and Pink Star respectively), New Phœbus, Rvecroft Glory, and Nellie Brown, and to follow later in flowering are A. J. Balfour, Western King, Niveum, Framfield Pink, La Triomphante, Mathew Hodgson, and W. H. Lincoln. The culture of really good pot plants for market requires considerable experience and skill, and much depends upon the conditions of things at the start. Short thick cuttings should be secured, and as soon as they break into growth they should be allowed plenty of light and air and fire-heat sufficient only to keep out the frost. Pot the plants firmly in good loam, to which stable manure and some bone meal have been added. The plants should be stopped when they are about 4 inches in height, and they may require stopping again later. The cultivator should aim at securing from six to twelve shoots of equal strength and height on each plant. If more shoots than are required are present, the weaker ones should be removed. Disbudding should be attended to as early as possible, and an important matter is to have the buds in such a condition that they will all open at or about the same time. When the plants are placed in the open, plenty of room should be given them to allow a free circulation of air about them. The pots may be plunged into the ground or in a bed of ashes. Regular attention must be paid to watering, especially after the buds are set. Liquid manure may be used freely at all times, unless the plants should appear to be too vigorous at the time the buds are setting, in which case stimulants should be withheld for a time, or until the buds begin to plump up. The liberal use of clear soot water will do much towards keeping off insects, and will also stimulate the foliage, but it is important that the soot water should be prepared some time before it is required for use, as it should be quite clear when used for syringing purposes.

NAMES OF FLOWERS, FRUITS AND PLANTS.—We are anxious to oblige correspondents as far as we consistently can, but they must bear in mind that it is no part of our duty to our subscribers to name either flowers or fruits. Such work entails considerable outlay, both of time and money, and cannot be allowed to disorganise the preparations for the weekly issue, or to encroach upon time required for the conduct of the paper. Correspondents should never send more than six plants or fruits at one time: they should be very careful to pack and label them properly, to give every information as to the county the fruits are grown in, and to send ripe, or nearly ripe, specimens which show the character of the variety. By neglecting these precautions correspondents add greatly to our labour, and run the risk of delay and incorrect determinations. *Correspondents not answered in one issue are requested to be so good as to consult the following numbers.*

PLANTS: *W. C. & Sons.* Eucalyptus Globulus; your specimen has reached the adult stage, in which the foliage undergoes a remarkable change from that of the ordinary or seedling plants usually met with in gardens.—*J. F.* The berries are probably those of Solanum nigrum, a very common weed in gardens in the south of England.—*J. H. B.* 1, Nephrolepis Piersonii; 2, Selaginella amœna; 3, Nephrolepis ensifolia; 4, Gymnogramme Pearcei; 5, Nephrolepis pectinata; 6, Pilea muscosa; 7, Nephrolepis tuberosa; 8, Polypodium appendiculatum; 9, Lastrea Filix mas; 10, probably Tecoma jasminoides; 11, Carex variegata; 12, Davallia dissecta; 13, Polypodium pustulatum.—*E. W. S.* a, Cattleya Trianæ; b, Cypripedium venustum; c, Cypripedium barbatum Warneri.—*Cym.* Cymbidium giganteum.—*T. H.* 1, Cymbidium longifolium; 2, Restrepia trichoglossa; 3, Dendrbium cymbidioides.—*E. R. M.* A variety of Cypripedium Harrisianum.

POTATOS FOR MARKET: *Hants.* By referring to our weekly market reports you will be enabled to ascertain the principal varieties cultivated for market purposes and their relative value. The amount of the crop per acre will depend upon the quality of the soil, the variety of Potato grown, the cultivation applied, and many other details. An average crop is from six to ten tons per acre.

TO DESTROY TREE STEMS: *E. D.* The butts of the trees may be destroyed by blasting with dynamite. They may also be destroyed by pouring a saturated solution of saltpetre into the butt, and afterwards setting a light to the saltpetre, when the whole will be destroyed by fire. A hole should be bored in the top of the stump in which to pour the liquid.

TRUFFLE: *H. R.* The fungus you send is the common Truffle (Tuber æstivum), a species indigenous to Britain and the Continent. Another species, Tuber brumale, which is the most common on the Continent, sometimes also occurs in this country. Altogether ten species or Truffle have been found in Britain, but some are small and only the above two species are eligible to rank as esculents. We cannot determine your species, found under Cedars, merely from description, but if you will send specimens we will examine and determine its name.

VIOLETS DISEASED: *H. H.* There is no fungous disease present on the specimens you send, but they exhibit a loss of vigour and strength. Try a more generous treatment in the matter of feeding, and afford more ventilation to the structure in which they are growing.

WEEVILS: *A. L.* The creatures feed on the foliage of Ferns and other plants at night time. They may be caught by laying white cloths under the plants upon which they are feeding, and after it has been dark for about an hour throwing a bright light on the plant, when the insects will be alarmed and fall to the ground. Should they not fall the plant should be shaken. Weevils hide themselves in the most cunning manner during the daytime.

THE HIPPEASTRUM.

I HAPPENED recently to look into that excellent botanical work the *Amaryllidaceæ*, by the Hon. and Rev. William Herbert, published in 1837. Herbert was not only a botanist, but an indomitable hybridist and horticulturist. He monographed the genus, writing elaborate descriptions of the various species known at that time, and his keen horticultural proclivities were displayed in the work of hybridising in his own garden at Spofforth. He enumerates 31 distinct crosses of specific forms made under his own direction. In the matter of selecting names for his hybrids he had to face a difficulty which seems to give some trouble even at the present day. For instance, a cross between H. striatifolium and H. vittatum he named striatifolio-vittatum. Other names were H. solandrifloro-bulbulosum, H. reticulato-bulbulosum, and so on. To seedlings from these semi-species he proposed to give such names as Juno, Ceres, Camillus, Napoleon, &c. These were termed sub-ordinary varieties, and deserved no place in a botanical arrangement. It is interesting to remark that the varieties of Cattleyas, Lælias, Cypripediums, &c., are now losing their botanical character in much the same way. In some cases the evidence as to the original species cannot be detected in the seedlings, and to simplify matters they will have to be named after heathen gods and goddesses as Herbert advised in the case of Hippeastrums.

It is not likely that any of the hybrid Hippeastrums raised so many years ago are now in existence. While Herbert was working in England, Mr. de Graaff, as early as 1790, was cultivating the Hippeastrum at Leiden in Holland. I have a letter before me from Mr. S. A. de Graaff, dated January 30, 1890, in which he states that his father's uncle had cultivated H. Johnsonii and H. vittata since 1790. He might have cultivated the parents of the first-named variety at this early date, viz., Reginæ (1728) and vittatum (1709), but he could not have grown Johnsonii, as this variety was raised by an amateur named Johnson, who had a small garden in Lancashire in 1810. We know, however, that Mr. de Graaff, senior, was a raiser of seedlings from 1830, and Mr. S. A. de Graaff since 1862; and many very fine garden varieties have been raised at Leiden in recent years. I can well remember the sensation caused by the introduction of the variety Empress of India some 20 or 25 years ago. Messrs. Veitch, of Chelsea, obtained the stock of this fine variety, and with their own superb crosses from H. pardinum and H. Leopoldii an impetus was given to the culture of this fine genus, which has resulted in the magnificent varieties now cultivated in gardens.

Perhaps no gardener in the world has improved the genus so much as Mr. A. Chapman, gardener to Major Holford, of Westonbirt, Tetbury. Not every gardener has the opportunity or the means of obtaining such a collection, and many, if they had, would not make such good use of it. I have seen perhaps every collection exhibited from Major Holford's garden in London, and noted the improvement in form, colour and substance of petals year by year. In April, 1900, quite a hundred splendid varieties were exhibited, and many of them had received certificates and Awards of Merit from the Royal Horticultural Society and other societies. The many rich crimson and dark red forms in the Westonbirt collection were remarkable on that occasion. In some varieties the characteristic green centre was present, in others this had disappeared; "stamped out" Mr. Chapman terms it, and so deep was the tinge of colour that the back of the petals in some instances had the same rich tone as the front, and many of the spikes carried four of these exceedingly large and well-formed flowers. What an improvement such varieties as Radiance, Lord Dalhousie, Poetry, &c., are upon the early crosses from Chelsonii and Empress of India. The advance in form, size, and substance of petals is as much marked in the light-coloured varieties.

White varieties had been in existence for some years, but the first white varieties to be produced from seed were of weakly constitution, and the flowers themselves were thin and not of good substance. Mr. Fielder produced a white variety, Fielder's White, far in advance of any other, and equal in quality to the best of the Westonbirt seedlings. There were many very fine white-ground varieties in the collection, marked with pink principally. There is no doubt that the Westonbirt collection marks the furthest advance yet made in Hippeastrums.

Cultivation.

The Hippeastrum is an ornament in any garden and, its requirements being understood, it is easy to grow. Sometimes the proper cultivation is not understood. I remember being shown round a garden where expense was no object, and was surprised to see a collection of the best-named Hippeastrums out of doors. The plants had been turned out after flowering to "ripen their bulbs." It is astonishing how this idea clings to some gardeners, and is equivalent to turning out Azaleas as soon as they have finished flowering instead of putting them into a warm, moist atmosphere until the flower-buds are properly formed.

Hippeastrums require a period of growth after flowering in order to develop the bulbs. Not until the bulbs have well plumped up and the leaves have begun to decay should water be withheld and air freely admitted to the structure. By that time, the season being advanced, warm weather will have set in, therefore the ventilators of the house may be allowed to remain open night and day. This will help in keeping the plants free from thrips, red spider, and other pests.

My collection was repotted in January, the flower-pots being plunged in a moderate bottom heat. The bulbs at such a time should be well furnished with healthy roots. It is a grave error to treat them so that the roots decay at the base of the bulbs; this is sometimes caused by keeping them for many weeks together on a shelf near the glass in a cool house, or it may result from excessive applications of water in the resting period. The best treatment is to allow them to remain in the plunging material. The roots run freely into this, and they require no water after the decayed leaves have been removed until it is time to repot them. The potting soil I use is one composed of good, fibrous, well-decayed loam four parts, decayed manure one part, and leaf-mould or fibrous peat one part.

The largest single bulbs may be repotted into 8-inch flower-pots, and smaller sizes into pots measuring 7, 6, and 5 inches in diameter, but taking care to avoid over-potting. The bulbs should be placed about half their depth in the potting soil; if this is fairly moist, as it should be at the time of using, no water will be required for two or three weeks, and even when it is applied, it should be poured from a small water-pot round the inner rim, to avoid wetting the base of the bulbs until the roots have freely started. The heat at first may be 50°, raising it as growth progresses to 55°, 60°, and ultimately to 65°. When the plants are in full growth water may be applied freely, but pots plunged in a hot bed do not require water frequently. The bulbs are likely to flower in three or four months after the repotting.

Raising Seedlings.

Every grower of Hippeastrums should raise seedlings by crossing the best varieties. It is easy to remove the anthers from the

partly-opened flowers with the fingers before the pollen is scattered, and as soon as the seed-bearing flower is fully expanded it is ready to receive the pollen from another variety. The seed will ripen in June or July, and may be sown at once. If it is sown thinly the plants need not be pricked out, and they will form quite strong plants by the end of the season. The leaves of these seedlings remain green during the winter, and if three of them are repotted in January or February into a 5 or 6-inch flower-pot according to their size, many of them, under fair treatment, will produce flowering bulbs by the end of the growing season. They will not, of course, be fully grown, but strong enough to produce two or even three flowers on a spike. The plants must be kept in good health during and after the flowering period. A strict watch must be kept for thrips, as this species frequently gets upon the leaves during summer, and it is not easily destroyed by fumigating, as the insects drop into the plunging material and get up again next day; therefore fumigate the plants if it is even suspected. A species of mealy bug or aphis hides itself in the loose material at the apex of the bulbs, and if this pest becomes numerous it is difficult to exterminate. All the loose skins must be removed and tobacco powder dusted on the parts infested. *J. Douglas.*

BROUGHTON CASTLE, OXON.

(See Supplementary Illustration and figs. 57 and 58.)

FROM the appearance of this beautiful old building, as seen in our Supplementary Illustration, no one would suspect that it was erected as far back as the year 1301, during the reign of Edward I. The castle is in a remarkable state of preservation, and forms the country residence of Lord and Lady Algernon Gordon-Lennox. Broughton Castle is situated a distance of about three miles from the town of Banbury.

The Supplementary Illustration, which depicts the south front and the eastern end of the castle, shows that the surroundings of the old buildings are most picturesque, and this—apart from the natural beauty of the spot—is due to the work and artistic tastes of Lady Gordon-Lennox, who is an enthusiastic gardener.

The water seen in the foreground of the picture is part of a broad moat which entirely surrounds the castle, but it is not, as is often the case, close up to the walls of the old fortress. Thus there is a considerable area of ground, forming as it were an island, in the centre of which stands the old baronial dwelling. The keep (fig. 57) is seen in our Supplementary Illustration to be midway between the castle and the parish church of Broughton, and adjoining the keep are some ruined embattlements.

The waters of the old moat in summer time reflect the sheen of the Purple Loosestrife (Lythrum salicaria), Spiræa Aruncus, Iris and other British plants. But in addition, large beds have been planted with cultivated flowering plants and ornamental trees and shrubs. The flowering plants are such as have a good effect when viewed from a distance, especially when seen from the mullioned windows of the old castle. The plants include broad breadths of Pæonies, Roses, Sunflowers of the choicer species, Foxgloves, Liliums, Kniphofias, Shirley Poppies, and many stately herbaceous perennials. The Sea Buckthorn (Rhamnus catharticus) finds in the banks a suitable rooting medium, and the tree flowers and fruits in profusion. In the water are broad patches of the white Water-lily (Nymphæa alba) with other native aquatic plants. In the centre of the lawn and almost in the middle of our picture is seen a plant of Yew clipped to resemble the gnomon of a sundial, and the figures are planted in a circular band with the motto, "Memory lives but the hour flies," in a similar outer band.

At the left of the sundial and opposite the windows of the drawing-room is a design worked out in flower beds cut in the turf. A central one is planted with golden Yews that are clipped somewhat formally, and beneath is a groundwork of Berberis (Mahonia) japonica. The remaining beds of the design are largely planted with annual and perennial flowering plants, but several circular areas are occupied by Roses. A short distance away, and in this same lawn, is a small water basin for the accommodation of choice Nymphæas of the "Marliac" type. It is encircled by borders of Roses.

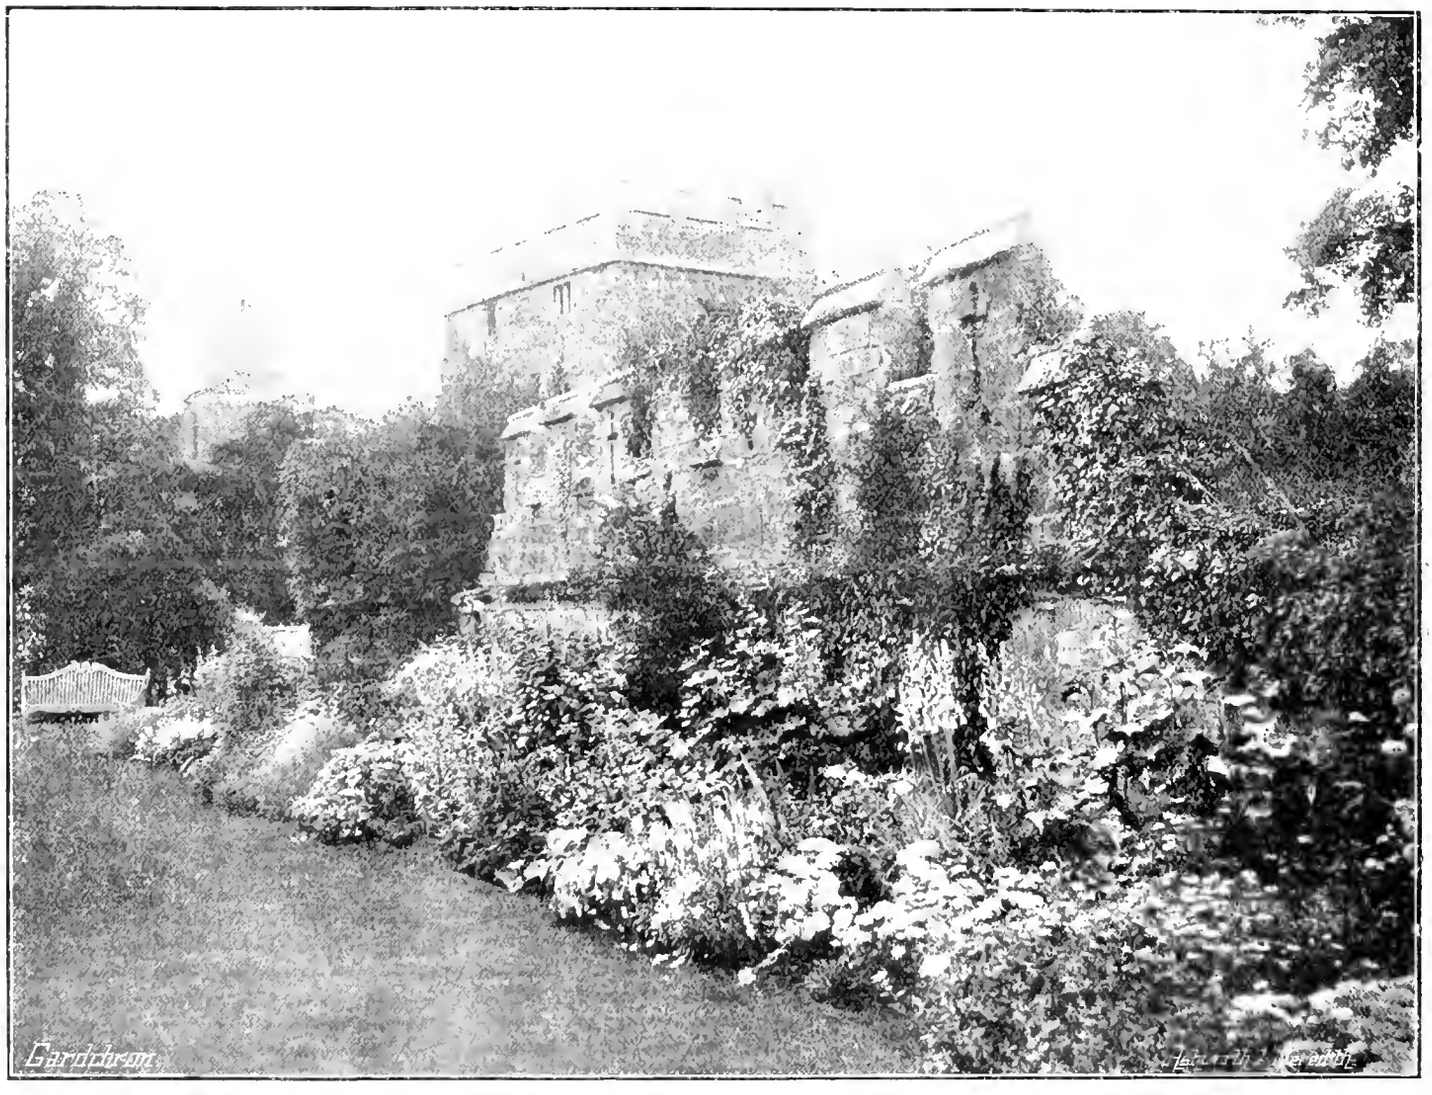

FIG. 57.—A FLORAL BORDER UNDER THE WALLS OF BROUGHTON CASTLE.

Herbaceous plants and annuals are largely employed in the embellishment of these gardens. Fig. 57 shows a portion of a very beautiful border that is filled with herbaceous perennials, and in their season annuals are cultivated in the foreground.

The old embattled walls lend a fine setting to this floral display, and the grass sward forms the path dividing it from a narrower border banked by a hedge of Yew, cut formally, and having at intervals examples of topiary in the form of birds with spreading tails. This border is usually planted with Ten-week Stocks over a groundwork of Cerastium, and having an edging formed of Mrs. Chas. Turner Viola. On the opposite side of this Yew hedge, which measures several hundred feet in length, is a dwarf band of Lavender extending the whole distance. Immediately opposite the residence the border is furnished with Liliums, of which a considerable quantity is cultivated each season, principally of the varieties L. speciosum rubrum and L. longiflorum.

There are small gardens surrounded with

The water basin is planted with choice Nymphæas, and is approached through arches of climbing Roses arising from the ends of a dwarf hedge in Yew, whose top is clipped in the manner of battlements. The circular beds are wholly planted with Pæonies, those heart-shaped with hardy perennials and annuals. Almost everywhere are Roses, the side borders being filled with dwarf plants that grow with the greatest luxuriance. The grounds are surrounded by bands of trees and borders of shrubs. The principal tree is the Alder (Alnus glutinosa), and one specimen is remarkable for its size and spread of branches. It resembles a large Oak tree, and its girth of trunk at a few feet from the ground is about 10 or 12 feet.

A thickly-wooded corner on the opposite side of the moat has been converted into a woodland retreat. The grass sward is cut into vistas or walks, and where opportunity has afforded, clumps of shrubs and strong-growing herbaceous plants have been planted. The grass in spring time sparkles with the flowers of bulbous

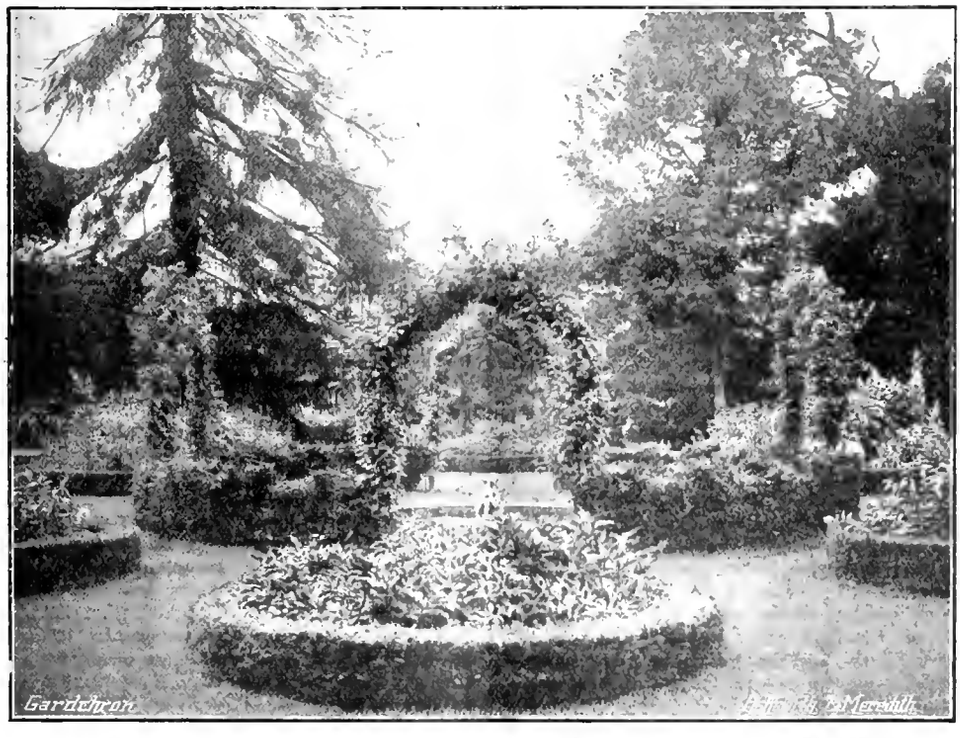

Fig. 58.—view of portion of the rose garden at broughton castle.

walls on the south-east of the castle; the first of these to be entered from the spot we have just described is known as the "Ladies'" Garden.

This small enclosure is literally a Rose garden, with broad borders of hardy flowering plants under the old walls. The Roses are massed in beds, each of one variety, and the whole forms a design of much beauty. We were informed that this was a neglected spot, until Lady Gordon-Lennox formed the Rose-garden. Another enclosed garden is next the one we have just described, and in this was taken the view depicted in fig. 58. The circular bed in the foreground is one of four alternating with others that are heart-shaped. The centre of the design is occupied by a circular water basin, around the rim of which is inscribed:—

"I sometimes think that never blows so red
the Rose
As where some buried Cæser bled;
That every Hyacinth the garden wears
Drop in her lap from some once lovely
head."

plants that are so admirable for associating in the turf for a pleasing effect.

Hereabouts is a herb garden, surrounded by a hedge of Yew. A water-garden in the centre is fed from the moat near by, and on the closely-clipped sward of banks around are seats; a lovely and cool retreat in the heat of summer time. Foxgloves grow in thousands with Funkias, Lilies, the Giant Hemlock (Heracleum giganteum), Polygonums, Spiræas of the hardier species, Tritonias, Roses, and a host of other bold subjects. One of the best Roses found to succeed beneath the shade of the trees is the variety Leuchstera.

On the east side of the mansion is a Rose-walk; the plants are trained over wooden arches, with festoons of Ivy connecting each arch, and all along the sides are standard Roses. Looking through this festooned path is seen the old parish church, a beautiful setting to this pretty scene. The church path separates the kitchen and fruit gardens from the pleasure grounds. The former are about two acres in extent, and they occupy the warm side of a slope.

There is a range of glass-houses, comprising vineries, Peach and Nectarine houses, plant stove, Melon pits, propagating house, &c. This quarter of the garden is largely planted with flowering plants, including Roses for cutting purposes, for although such a wealth of flowers adorns the beds and borders of the pleasure grounds, none is cut for decorative purposes. The gardens are under the care of Mr. George Low; they form a pretty setting for the noble building, which has survived through so long a period.

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM CRISPUM FOWLERIANUM.

This very finely blotched variety of O. crispum, which was illustrated in the *Gardeners' Chronicle* on May 4, last year, is again in flower with J. Gurney Fowler, Esq., Glebelands, South Woodford (gr. Mr. J. Davis), the inflorescence now bearing seven blooms. It is a grand variety, with deep blood-red markings on a clear white ground, and its fine qualities are well displayed on its second flowering, although the blooms are rather smaller than that from which the illustration was prepared, probably on account of its blooming two months earlier this year than last. The reverse of the flower is almost as richly coloured as the face, and the upper surface of the column is coloured deep chestnut-red.

ODONTOGLOSSUM ARDENTISSIMUM GLEBELANDS VARIETY.

This distinct variety, which is now blooming in the collection of J. Gurney Fowler, Esq., was raised by Messrs. Sander & Sons between a fine form of O. Pescatorei and the blotched O. crispum Truffautianum, and it was anticipated that a heavily blotched flower would result. In effect, however, the Glebelands variety may be compared to a very large and beautifully-formed variety of typical O. Pescatorei, the only trace of spotting being in an occasional red spot on some of the sepals; some of the flowers have all the sepals bearing spots, in others only two, and in others one. The flowers are very broad, and of fine substance, clear white, with a charming rosy flush on the sepals, and a broad transverse red blotch in front of the yellow crest of the lip.

VARIORUM.

"FORMATION OF SNOW ROLLERS."

At the meeting of the Royal Meteorological Society, held on the 19th ultimo, Mr. C. Brovett read a paper describing the formation of "Snow Rollers," which he observed at Ryton-on-Dunsmore, near Coventry, on January 29-30, 1907. There had been some snow showers during the afternoon and evening, amounting to a depth of about 1½ inches. The next morning the snow was cleared away to the bare grass, except for slight bars of snow across in tadpole-like markings, whose tails all pointed to the direction from whence the wind had been blowing all night, viz., north-north-west, and at the heads of which was heaped up the snow that had been on the bared grass, all neatly turned over in a roll. It seems that the flakes of a light, fluffy layer of surface snow are made adhesive by a rise in the temperature of the air above the freezing point, while the undersnow remains cold and dry, and the particles of damp surface snow are thus enabled to adhere to each other, but not to the dry undersnow. A strong wind may then push over little projections of the surface snow, and start them rolling, when of course they will travel and grow until the resistances overcome the propelling power of the wind. These "snow rollers" vary in size, some being only a few inches in diameter, while at times others have been seen 2 feet or more in length.

THE GENUS PHORMIUM.

THE species of Phormium or Flax Lilies have been used somewhat freely in conservatory decoration and also in connection with sub-tropical bedding, but their hardiness in the sheltered garden is not fully realised. They are very interesting objects in the landscape, and are peculiarly fitted for association with garden architecture of almost every description; their sword-like foliage, sometimes rigid and at other times with drooping tips, blends well with architectural lines. But at the same time there is that freedom of growth that makes them easy to associate with all that is good in the informal garden, provided the plants are boldly grouped on broken ground in which protected sites are always abundant. A sheltered position is very necessary even for the hardiest species; their beauty lies in the elegant foliage, and if this is liable to suffer damage by winds, their beauty is doomed from the first. One cannot regard them as being as hardy as Oaks, for in common with many New Zealand plants they find the winters of very cold districts too much for them. Wherever I find Phormium thriving in the open garden, it is invariably on sloping ground or in naturally well-drained soils. The old-established clumps by the waterside in Edinburgh Botanic Gardens probably owe their immunity from harm to their elevated yet sheltered position. I have studied these plants for some years, particularly noting their hardiness, and other examples teach the same lesson elsewhere. The plants are valued more for their foliage than for their flowers. Although there is a rugged type of beauty in a dozen long, arching peduncles of a curious bronze-blue hue, sparsely studded with yellow or buff flowers that always appear ill-fashioned, and are borne singly or clustered, one cannot compare them favourably with those of most Liliaceæ. The plant is only beautiful as a whole; the inflorescences removed from the plant are not.

The cultivation of the various species of Phormium is solely a matter of light dry soil and shelter. Seeds germinate quickly and the young plants grow rapidly in a cool house during their first year; afterwards, till strong enough to hold their own in the open, they may be grown in a cold frame. Propagation of garden varieties that do not reproduce themselves by seeds, is effected by cutting the back rhizomes into as many pieces as there are leaf scars. A bud is present at the base of every sheathing leaf, but does not grow unless the leader be injured or removed. The pieces of rhizome should be bedded in sand in a moist, heated frame till growths appear; these will make roots in due course.

The root and leaf system of Phormium resembles that of many lilies, but is very much stronger. Several plants transplant badly at all times, and where old-established clumps are split up, the leads should be re-started in pots under glass and frequently syringed till re-established. Grouping of the plants in the open should be deferred till April, and in planting, the ball of soil should be disturbed as little as possible. Under no circumstance would I recommend planting in autumn or winter. Growth that is made unchecked throughout a summer season, is hardy and well ripened, and would survive winters that would prove fatal to a greenhouse-reared or mutilated specimen. When once a colony is established, it is practically safe; individuals protect one another, and the severest frosts will not absolutely destroy them if the soil is well drained.

There are only three species in cultivation, and of these the hardiest is the poorest.

P. Cookianum (*P. Hookerianum*, *P. Colensoi*).—A dwarf species not uncommon in gardens. The growths are fan-shaped clusters of green leaves, with grey-blue reverse, generally 3 feet high; the inner surfaces of the leaves glabrous, the outer slightly rough. The inflorescences reach 6 feet in height, and consist of scattered buff-yellow flowers that are frequently aggregated into verticals, and are sparsely borne in late summer. This plant is quite hardy. I have grown it well in veritable bog earth full of stagnant moisture, but the best specimens were those on a sloping bank. In a light, sandy soil this plant makes handsome leaf clusters that a landscape gardener would appreciate.

Var. variegatum is a rare variety at present. Its foliage is handsomely variegated with creamy-white, and it stands the winter well.

P. Hookeri forms an imposing clump of bluish-green leaves recalling those of Canna in their tint. They are 5 feet long, produced in broad, fan-shaped clusters a yard across, and as they age the tips fall over, giving the plant a pendulous aspect. The spikes are 8 feet long, sub-erect, and bear quantities of dull red flowers that are not devoid of decorative character. The finest specimen I have seen of this Phormium is in the Rev. Canon Ellacombe's garden at Bitton, near Bristol. The specimen was in full flower at the time of my visit, and it impressed me with its value for the larger types of rock-gardens. The giant clump of sword-like leafage was very attractive. It is a rare plant in gardens.

P. tenax.—The common New Zealand Flax, an imposing plant for the large formal garden. The leaves are arranged in fan-like clusters that form a clump 8 to 10 yards round and more than 6 feet high; every sword-shaped leaf is perfect in outline as can be. The flower-spikes are often 10 feet high, the flowers are commonly of a reddish-buff colour, but specimens vary considerably in this respect. This species is quite common in large gardens where I have seen it grouped in clumps on lawns, or grown in tubs to be used as specimen plants on terraces. Abrupt corners have been artistically filled with it, and as a conservatory specimen one meets it in almost every garden of any size. Its hardiness in many cold districts is surprising. I have known old specimens survive winters that have proved fatal to many plants recognised as hardy, and I should have no hesitation in planting P. tenax where I was certain of wind shelter and a well-drained soil. In very cold gardens offering every risk of failure, I would trust the Powerscourt variety to do its best, and should not expect disappointment.

Var. purpurea is a striking form, whose leafage is purple tinted, and when quite young shows a tint of blue that proves very attractive. I have not seen such giant specimens of this, but am confident it is as hardy as tenax, and in the matter of leaf colouring it is one of the best "foliage" plants one can grow.

Var. variegata is a popular conservatory variety, and may be used in many ways. It is an elegant plant, whose tall, sword-shaped leaves are freely variegated with yellow and white. In common with most variegated Monocotyledons, it suffers, in very hot and in very cold weather, from injury to the whitest parts of the variegation, and it is not an uncommon circumstance to find a particularly well "coloured" leaf partly rent in two, the tissues having become seared where there is least chlorophyll. Shelter from winds is therefore imperative, and, in addition, the protection of some deciduous, small-leaved tree as a sun screen is desirable.

Var. Veitchii is an attractive form of variegatum, and possesses foliage which is narrow and quite erect, with a variegation in the form of small stripes of white. It is more liable to disfigurement than the true variegatum and is also less graceful, but it proves excellent for tub culture, and it is to be recommended for that purpose. *G. B. McM.*

PLANT NOTES.

SPARMANNIA AFRICANA.

THIS greenhouse plant is a native of South Africa, where it is known as the "Stock Rose," and in its native habitat it flourishes along the edges of forests as a rampant weed. The species is a very old inhabitant of gardens, having been introduced through Dr. A. Sparmann (after whom it is named), a Swedish botanist, who accompanied Captain Cook on his second voyage round the world.

Sparmannia africana is a soft-wooded shrub attaining to a height of from 10 to 20 feet in its native country, with the younger stems and branches more or less herbaceous. The alternate, hairy leaves are light green in colour, cordate-acuminate in shape, 4 to 6 inches long, with from five to seven angular points; the blade is pendulous, with an erect leaf-stalk 3 to 6 inches long.

An inflorescence of the plant is figured in the *Botanical Magazine*, t. 516, where the writer remarks that "the flowers are produced in the same manner as in the common Pelargonium, which it is very like in its inflorescence, the flowers nodding before they are expanded, and becoming erect as they approach maturity." The sepals and petals are pure white; the former are covered on the outside with hairs; the centre of the flower is occupied by a tuft of purple stamens, surrounding which is a ring of barren yellow filaments, the distinctive character of the genus.

Where space can be afforded, it is probably most effective when grown as a standard, but small, bushy plants also furnish an abundance of bloom.

Belonging to Tiliaceæ, an order containing several valuable fibre-producing plants, it is not surprising to learn that an excellent fibre has been obtained from the stems of Sparmannia. An analysis of this fibre, which is sometimes known as "African Hemp," is given in *Technical Reports and Scientific Papers of the Imperial Institute*, p. 93, and a note in the valuable **Forests and Forest-flora of Cape Colony*, recently published, also calls attention to the plant. This latter work states that the Kama Fibre Syndicate was formed to exploit the fibre, and, although it ceased operations after a few years, it was not owing to any inherent defect in the fibre itself.

The yield of fibre under cultivation is estimated at 10 tons per annum per acre of raw material, which equals half a ton of clean fibre per annum per acre. The value of a sample sent to England was £32 per ton, that of flax at the same time being £36, of Mauritius Aloe £33, and of New Zealand fibre £30 per ton. The cost of preparing the fibre is about £8 per ton.

The "Stock Rose" is said to come up spontaneously in forests cleared by burning the undergrowth, and is also readily raised from seed. The appearance of a plantation when the plants are in flower is said to recall that of a coffee estate in India. [A double-flowered variety was illustrated in our issue for April 14, 1883, p. 477.—ED.]

ITEA VIRGINICA.

This pretty North American shrub, referred to by *F. M.* on p. 115 is very interesting from the fact that when in full bloom it is particularly attractive to butterflies, especially to the showy members of the genus Vanessa.

The period at which it flowers (midsummer or somewhat later) is early for the "Red Admiral" to put in an appearance, but a few specimens may generally be seen hovering over the flowers, which are nearly as attractive to these butterflies as are the pink flowers of Sedum spectabile later in the season. *H.*

USES OF THE MOTOR IN HORTICULTURE.

(Concluded from page 116.)

THE smallest in size, but by no means the least useful motors for horticultural purposes, are motor lawn mowers and motor rollers. Steam and electrically-propelled mowers were in use twelve or more years ago, and were described in the *Gardeners' Chronicle* for March 28, 1886, p. 401; but the petrol-driven motor has only been applied to the lawn mower comparatively recently. A description of one working very satisfactorily at Kew appeared in the *Gardeners' Chronicle* for June 20, 1903, p. 398, and in the issue for July 25, 1903, p. 61, some notes were published concerning another machine of a similar character.

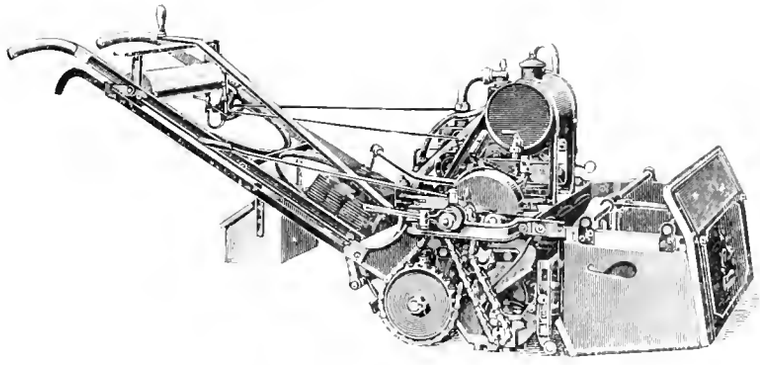

FIG. 59.—MESSRS. ALEX. SHANKS AND SON'S PETROL MOTOR MOWER; SIZE 30 INCHES, WEIGHT 7 CWTS.

The larger mowers are constructed with cutters 42 inches in width, have a powerful water-cooled engine, weigh nearly 1 ton, and cost almost £200. These are very useful where a large area of grass has to be kept well mown and rolled, and, being fitted with a seat for the driver, steering wheel, reverse gear, and levers for throwing the cutters out of gear, they are extremely handy, and capable of being easily worked by one man. Others of various sizes are obtainable, and the smallest are fitted with an air-cooled engine, handled like an ordinary mower, weigh about 3 cwts., and cost about £70. Even with a small machine a man can do a great deal more work than with a horse-drawn mower, and provided he is fairly intelligent, he should be able to keep the motor in order at very little expense. In these days when the motorcar is so common in country houses, a motor mower could be kept in order by the mechanic in charge of the car, and the handy man be employed to drive the mower and keep it clean.

The great amount of work that can be performed by the machine is not its only recommendation to the gardener. Where horse mowers are employed it has always been found difficult to entirely prevent the horse's hoofs from damaging the turf; but with motor mowers there is no trouble of this kind. The management and steering of the motor mower are easy to a man who has had two or three days' practical instruction from the makers, even though the sward is broken up by numerous flower beds and shrubberies.

Motor rollers are made to which either grass cutters or lawn mowers may be attached, and the two functions of cutting and rolling carried on simultaneously.

For ordinary lawns the mower itself is an excellent roller, and the weight may be, to a certain extent, regulated, whilst in the winter the cutters may be either removed or put out of gear, and the machine used as a roller only. This adaptability makes it of particular value on golf courses and on athletic grounds. Their extensive employment for this work is undoubtedly their best recommendation, and as, in my opinion, there is nothing so satisfactory to the prospective purchaser as the experiences of other users, a day or two would be usefully employed devoted to such inspection and enquiry.

Another duty which gives the gardener much heavy labour during dry summers is the quantity of carrying work involved in watering. Every suburban householder thoroughly appreciates the value of the familiar garden hose attached to the scullery tap, and it would be difficult to say how much greater would be the value of a small, mechanically-driven pump in a large garden, and as the engine on the lawn mower or roller may be used to drive a pump by means of a belt, it is another duty for which the machine should receive credit. Water thrown in the garden cannot be neglected, and as it is perhaps heavier than any other task, involving, as it does, much bucket work and hand pumping, any labour-saving method would be welcomed.

The machines are well worthy of consideration, and the accompanying illustrations are representative of the types of several firms, the names of which are already well known to horticulturists. *Hugh Miller, F.E., M.E.*

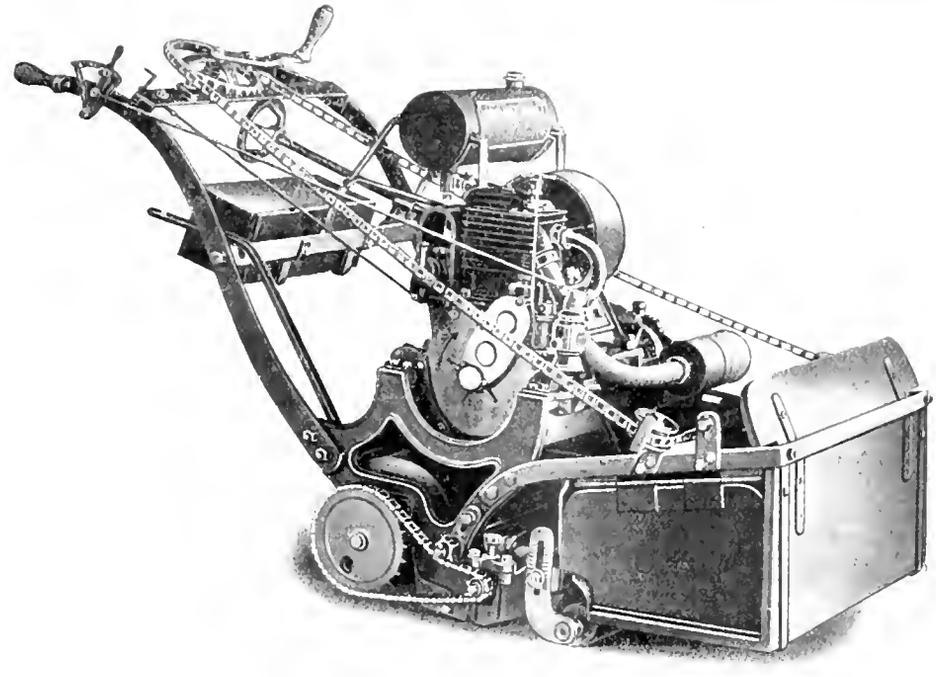

FIG. 60.—MOTOR LAWN MOWER MANUFACTURED BY MESSRS. RANSOMES, SIMS AND JEFFERIES; SIZE 24 INCHES, 2¾ H.P. PETROL MOTOR WITH MAGNETO IGNITION.

GRAFTING VARIETIES OF CLEMATIS.

THE most suitable stock for propagating by grafting the many beautiful hybrids and varieties of Clematis is *C. vitalba*, it being superior for this purpose to *C. flammula*, which was largely used formerly.

To secure the stock plants, seeds should be sown in the spring, and the roots may be grafted the following season, but it is better to transplant the seedlings at the end of the first year, in order to obtain stronger plants. If they are used when they are one year old the entire seedling is required as a stock, whereas in the second year many suitable pieces of roots can be severed from each plant, and the latter can be again planted so as to form new roots for the following year, but it is advisable to discard the plants after their third or fourth year.

The plants of the varieties that are required to be propagated are, if perfectly hardy, wintered in the open. During January or February they are pruned and placed indoors in a gentle heat, and this quickly causes the buds to break into growth. After a lapse of three or four weeks the young shoots are suitable for furnishing grafts, and it is essential that they should be worked before they become too ripe, otherwise the buds will not develop into shoots during the same year.

The propagating-house should contain cases which can be kept close and have a bottom heat of from 70° to 75°. If a layer of about 6 inches of cocoanut-fibre refuse be placed in the bottom of the propagating cases, it will form an excellent material in which to plunge the pots to their rims, which is a great advantage.

When the wood of the scions is in a suitable condition it is cut off the plants and severed midway between two nodes (joints), and care should be taken to prevent the shoots from becoming dry or withered.

In the axils of the petioles of each pair of leaves are the buds, and at the scion being of sufficient thickness, a sharp knife can be carefully used to split the stem down between the buds, thus securing two grafts from each part, but if sufficient scions are obtainable without this operation, they are better used whole.

Of the many methods of grafting, that known as the whip system is to be recommended, and great care is needed in making the cut. This should commence at the joint, and only a little of the tissue beneath the bark should be taken off. The cut should be finished by turning the knife a little, in order to sever the stem almost horizontally. This horizontal portion does not come in contact with the stock, the result being the formation of a callus over the exposed surface, and in a short time roots are emitted from the callus, and these enable the plant to become eventually established on its own roots. The stocks having been taken up from the ground, a suitable piece of root is selected and made ready for the scion, and the two are then bound firmly together with moist raffia. When the tying is completed the union should be covered with damp Moss until it is convenient to pot the plants. The compost for potting should be light in texture and moist, the latter precaution being essential, because no water should be given to the plants at their roots until growth has commenced.

The most suitable pots are thumbs, and the scion should be potted as deeply as possible without covering the buds.

After the pots have been plunged, the cases should be closed, and with the use of sheets of brown paper the light should be excluded for at least a week. The cases will require to be kept open for half an hour daily in order to allow the accumulated moisture to escape.

In about a fortnight growth will have commenced, and when the new shoots are a few inches in height the plants should be taken out of the cases. The growths should immediately be made secure by tying them to supports, otherwise they will be liable to become broken at their bases.

A few weeks later they will be ready for shifting into 5-inch pots, and after this potting they should be given a cool treatment. In July or August the plants should be plunged in the open, and as soon as they are thoroughly hardened they will be ready for their permanent quarters. *W. B. Little.*

The Week's Work.

THE ORCHID HOUSES.

By H. G. Alexander, Orchid Grower to Major G. L. Holford, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Lælia anceps and its varieties.—These winter-blooming Mexican Lælias merit a place in every collection. Complaints are sometimes made that they are shy flowering plants, but such is not our experience. The coloured forms are more compact in growth and certainly produce their flower spikes much more freely than most of the white-flowered varieties. The flowering season is now past, and the plants should be placed in a suitable position to rest until the season comes round again for them to commence growth. Upon the treatment afforded them during this period will largely depend the success or failure to flower them well. The longer the plants are at rest the better is the chance of obtaining flowering growths, as growths completed late in the autumn seldom fail to produce flower spikes. Place the plants in the lightest and most ventilated part of a cool intermediate house, and afford the roots only sufficient water to keep them healthy and the pseudo-bulbs plump. If a large batch of these plants is cultivated and there is not a special house devoted to them, it will be advisable to set apart a portion of a house for their culture, choosing a position where the rays of the sun will reach the plants at all seasons, and when the ventilation can be so arranged that plenty of fresh air may be admitted whenever the outside conditions are favourable.

Repotting.—The Lælias belonging to this section produce a cluster of new roots from the last made pseudo-bulb shortly after the flowering season is past, and the white varieties do this much earlier as a rule than the coloured forms. When these new roots are first observed, attention should be directed to the repotting or resurfacing of the plants, but on no account should they be disturbed unless it is really necessary. In cases where repotting must be performed, let the whole of the compost be shaken from the roots, removing any dead roots and the back pseudo-bulbs that are no longer of service to the plant. Teak-wood baskets are preferable to pots or pans as receptacles, especially when the plants have to be suspended from the roof rafters. These should be sufficiently large to accommodate the specimens for a few years without further root disturbance. When repotting, place all the "leads" towards the centre of the baskets, so that the rhizomes will have a greater distance to travel before growing over the sides. Provide ample means of drainage and employ a similar compost to that recommended in last week's Calendar for Cattleyas, as a rooting medium. Newly potted plants are best placed on a stage for a period, and sprayed overhead daily till such time as new roots have penetrated the compost, after which they should be treated as previously advised. If the rooting medium should get into a soddened condition the new roots will decay directly they enter the compost.

PLANTS UNDER GLASS.

By Thomas Lunt, Gardener to A. Stirling, Esq., Keir, Perthshire, N.B.

Palms for decorative purposes.—These should be cultivated in as small pots as possible, and when they require to be repotted a rich compost should be employed that will remain nutritive for a long period. It may be formed of strong loam, with ¼-inch bones added freely. This will be suitable for strong-growing Palms, such as most of the Kentias, Arecas, &c. The soil should be pressed down the side of the pot very firmly, as this will help to induce compact growth. For the less robust sorts a compost of peat, loam, and sand should be used, but potting should be done firmly, as in the case of the stronger-growing sorts. For the species Cocos Weddeliana a compost of peat and sand only should be used, unless the loam is of a very light nature, and then only a small portion. Any Palms that do not require a larger pot than they now occupy should have the top soil pricked up and removed, afterwards top-dressing with fresh soil and some good artificial manure. Palms can be kept in good health for many years together without repotting, if attention is given to feeding with suitable manures and the roots are never allowed to suffer from drought. Shade the plants from all direct sunshine, and syringe them freely on every favourable occasion, taking care to syringe the under side of the leaves. Keep a sharp look-out for thrips. It will be found that occasional syringings with clear soot water will help to keep insects in check, and waterings of clear soot water will improve the colour of the foliage.

Gloriosas.—The shoots are now growing freely, and should be encouraged to run up strings similar to those used for Dipladenias, but if the plants are required for exhibition they should be trained on a ballon-shaped trellis from the commencement, first training the shoot as low down to the rim of the pot as possible, with a slight incline all round as the shoot extends. Turn the plant round once a week, so as to prevent it becoming one-sided, and place it in as light a position of the hothouse as possible.

Rhododendrons (Azaleas).—Plants that have done flowering should have all the seed pods picked off, and be kept in an atmosphere heated to 60° to encourage as much growth as possible, syringing and shading them in bright sunshine. As soon as the plants are seen to be growing freely, any that require repotting should be given attention. The old ball must be pricked up slightly all over, and notice should be taken that it is in a fairly moist condition; if it is not, it should be soaked in a pail of tepid water before potting. A compost of peat and sand alone is best for Azaleas. Great care must be taken in potting to see that the soil is made very firm, adding small quantities at a time. Following the potting, watering must be done very carefully. Ascertaining the weight of the plant by lifting it is the best way of learning if these newly-potted plants require water, but this cannot be done in all cases. Plants that have flowered freely and have not been re-potted will be benefited by a slight sprinkling of Peruvian guano on the surface of the soil, which should be slightly pricked up afterwards with a small sharply-pointed stick. The soil of any pot plant which has a hard, close surface should be pricked up occasionally, so as to change the channels for the water and admit air more freely into the soil.

PUBLIC PARKS AND GARDENS.

By James Whitton, Superintendent of the Parks and Open Spaces in the City of Glasgow.

Formation of parks.—Following on my remarks pertaining to playgrounds for children, I have now to deal with those larger areas which more properly fall within the designation of a public park. These may vary in size from five to 500 or more acres. Not two of them will be alike in character of situation, but each will require special study and treatment to suit the needs of the district in which it is situated. This point is particularly true in respect to the necessities of large towns where there usually are well-defined residential and industrial districts. One of the most frequent causes of discord in municipalities is the question of the relative treatment of districts including that relating to the provision of public parks. Therefore, in the planning as well as in the subsequent management of parks, due care must be exercised to prevent the creation of any feature which might give use to friction between the residents in different districts.

Park design.—The subject of park design is one on which the divergence of opinion is as wide asunder as the poles. It is also one that demands, from a municipal point of view, the most careful consideration and study. When one bears in mind that municipal rates everywhere are tending to increase yearly, and that the expenditure of public money is rightly becoming more closely scrutinised, it is the duty of responsible persons to see that full value is obtained for every penny spent. Therefore the aim ought, in the first instance, to be directed towards making the place realise to the full the object of its existence. In some towns the "park" is only a crudely-treated playground, the outstanding features of which consist of an obtrusive bandstand, a series of paths leading to no feature in particular, a few scraggy trees and shrubs dotted about without any meaning, and a general air of untidiness prevails. Not attempt is made by the authorities to make the place one of such interest and beauty as to add considerably to the amenity of their town, or to serve as a pleasure resort for the general community where, along with the means for muscular exercise for the young and vigorous, provision is also made for the enjoyment and physical recreation of those whose years and inclinations demand recreation of a less exacting nature. In such cases there appears to me to be a lack of appreciation of the higher ideals of civic government. On the contrary, there are parks where the treatment runs to the opposite extreme, and is too "villa-gardenesque" in character. The general design may be excellent, but nevertheless be ruined owing to failure to appreciate its points and purposes. Over the greater part of the area trees and shrubs are dotted about in a haphazard manner, and they have been so trimmed and pruned as to destroy all the beauty and character they naturally possess, and cause them to wear that air of smug complacency characteristic of Dutch dolls. The grass swards and paths are faultlessly kept, while the intricacy of the design of the flower-beds is only equalled by the brilliancy and garish display of their occupants. Fortunately, this type, which was chiefly encountered in smaller parks, is less in evidence at the present time than it was some years ago. The flower-bed business is one which acts as a pitfall to many excellent young gardeners. They must learn that while townspeople like to see flowers, they do not want them in every corner. These extreme examples are stated simply to direct the attention of those young gardeners who are desirous of entering upon this branch of their profession, to a matter which they should study on every occasion, so that when their opportunity arrives they may avoid faults of management of the kind indicated above, and be in a position to direct the authorities towards the adoption of a sounder and simpler system.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Spring flowers.—Bulbs are now making rapid progress, and it will be well to mulch the ground with manure from a spent Mushroom bed or with Cocoa-nut refuse. Unless this is done, heavy rains are liable to spoil the foliage and flowers by splashing. Beds and borders of spring flowering plants should be made neat and clean before the flowers open, as the work can be done much quicker and with less damage than afterwards.

Calceolarias, Pentstemons, Gazanias, Alyssums, &c., raised last autumn from cuttings, and that have been wintered in cold frames, ought now to be given full exposure unless there is frost. Pinch the leading shoots, to induce the formation of side growths. Gaillardias raised from seeds sown last July in the open and transferred to unheated frames for the winter need full exposure to the weather before being planted out. Pentstemon barbata (Chelone barbata) treated in the same manner as Gaillardias, produce tall spikes, densely tufted with drooping red flowers, and are very handsome.

Gladiolus.—If early flowers are required in beds, borders, or for cuttings, some of the earliest and hardiest varieties, such as Gladiolus, Colvillei alba, The Bride, rosea, and rubra, and G. brenchleyensis, bright scarlet, should be potted into 4-inch pots and placed in unheated frames, and when well rooted be transplanted. Or they may be planted now in the position in which they are intended to flower, provided the ground is in good working condition.

Lobelia cardinalis and varieties placed in heat early in February will now be in good condition for potting; use 4-inch pots, and a compost of leaf-soil, loam, and sand. When pulled apart, divisions of the plants with roots and two shoots are quite large enough. Keep the plants in gentle heat until they have become established, after which time they should be removed to cooler quarters.

Garden walks require constant attention to keep them in good condition, and nothing contributes more to the general good effect than well-kept paths. During the present month much can be done, even with the hoe, to lessen the number of weeds that would otherwise appear in the summer months. But when weed-killers are used, the advantage is very marked, not only are weeds and moss killed, but a brightness is imparted to the gravel and the smooth surface is retained. Accidents to animals or vegetation from the use of the poison may be easily avoided when the instructions for use issued by the vendor are properly carried out. Frost having loosened the surface, frequent rolling will be necessary. Box edgings may now be lifted and relaid. If the gravel has become dirty on certain paths, let fresh gravel be applied.

Roses.—The hardier climbing varieties should by this time have all old wood removed and the young wood laid in and securely fastened. The yellow and white Banksian Roses, when allowed to assume a natural form against a wall in some warm and sheltered corner (as is essential for these varieties), need very little pruning beyond the removal of old and weak growths after the flowering period in July. When strong growths 20 feet in length are well flowered, they are very handsome.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Planting.—Where the planting of fruit trees was interrupted in the autumn by unfavourable weather or other causes advantage should now be taken on dry days to prepare the stations as previously recommended. Provide drainage where necessary, and get a supply of fresh compost in readiness, so that no delay may afterwards occur in completing the work of planting, which should be pushed forward at every favourable opportunity. It is important that the soil should be sufficiently dry to bear treading with the feet and firming well over the roots. Supply each tree with a suitable stake immediately after planting, tying the tree to the stake so as to prevent its being swayed to and fro by winds. Stakes for standards should be driven into the sub-soil before the trees are planted.

Raspberry canes.—The canes upon established plantations may now be shortened to a plump bud and tied up singly to strained wires as recommended in a previous Calendar. Being gross feeders, yet surface-rooting plants, liberal mulchings are necessary. Unless the surface soil has become hard, no digging should take place, and even then the surface should only be lightly pricked over with the fork. It is not yet too late to plant young canes. The ground for these should be thoroughly prepared, as was recommended in the Calendar published in the *Gardeners' Chronicle* for January 11. A true stock of the variety Superlative is still the best red fruiting variety. Baumforth Seedling and Northumberland Fillbasket are also two good varieties. Guinea is the best yellow variety. November Abundance and October Yellow are two good and reliable autumn-fruiting varieties. The canes of these autumn-fruiting varieties should be cut down to the ground level in spring.

Apricots.—The buds of these trees have plumped up very fast during the recent mild weather, and trees growing against the warm wall of a house will soon be bursting into bloom. At this stage the bloom-buds are very susceptible to injury from frost, and the protecting material should be placed over the trees on frosty nights. The material should, however, only be made use of in severe weather or when frosts threaten, it being necessary that the trees should be fully exposed both night and day in mild weather. Care should be taken not to dispense with the means of protection before the young fruits are sufficiently protected with the foliage of the trees.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Lettuce.—Plants raised from seeds sown in autumn which have been wintered in unheated frames can now be safely planted out in a warm, sheltered part of the garden. If room can be found for them at the foot of a south wall or fence, it will make a considerable difference as to the time when they will be fit for use. Lift the plants with a garden trowel, taking care to retain as much soil about the roots as possible. Plant them very firmly and apply a good watering. Where space can be spared, part of the crop should be planted out into unheated frames as near the glass as possible, using soil which is known to be free from wireworm. Both the Cabbage and Cos varieties respond well to this method of culture; the growth being naturally much quicker, the quality at this season is much improved. Plants raised in heat should be pricked off immediately the second leaf appears, cultivating them in unheated frames. Make further sowings of both Cabbage and Cos varieties under glass.

Forcing Asparagus.—One more good batch of crowns should be lifted and planted in frames that are not provided with bottom heat; the protection of the glass alone will be sufficient to encourage the growth just in advance of that in the open air. Never allow the roots to be exposed to the air for one minute longer than is necessary; more failures are caused by such exposures than any other cause.

Asparagus beds.—If it is contemplated making and preparing new beds, either by way of supplementing those which have done duty for some years or for further increasing the supply, the work should be proceeded with at once and all got in readiness for planting in the first week of April. Fortunately, Asparagus does not need all the trouble and expense that was generally thought necessary by our forefathers, the primary requirements being good drainage and a liberal depth of soil. On very wet land the beds should be elevated above the natural level of the staple, and alleys thrown out during the winter months, but on light, porous soils this work is not only unnecessary, but injurious. The beds should be thrown out 4 feet wide, thus allowing three rows of plants to a bed. An alley 2 feet in width should be made between each bed. Should the sub-soil prove to be very bad, this should be entirely or partially removed, and be replaced by a more suitable mixture.

Celery.—The main and last sowing should now be made in pans and placed in a gentle heat. Prick out seedlings that germinated last month into boxes, putting the plants at distances of 2½ to 3 inches all ways. Do not expose these plants to great heat, but guard them as much as possible from suffering a check to growth. The latest Celery still in the ground ought now to be lifted and stored in fine soil or cinder ashes under the shade of a north wall; this will retard the plants from running to flower.

Celeriac.—Seeds of Celeriac should also be sown at the present time.

Egg plant [*Solanum Melongena*].—This is both useful and ornamental, and should be grown by all who possess a reasonable number of glass-houses. Both the white and purple kinds are worthy of cultivation, but the former is generally preferred for culinary purposes. Seeds may be sown now, and the seedlings raised in a hot, moist atmosphere. Cultivate them in a similar house, and they will fruit well in pots measuring 6 or 7 inches in diameter. The plants will need to be protected from red spider.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Planting Vines.—Should the planting of vines be contemplated, it should be attended to as soon as the canes, previously prepared for the purpose in a cool house, are bursting their buds. If the borders have been formed according to the directions recently given, those inside the house will now be in a suitable condition for the reception of the vines. When planting, make the holes sufficiently large to enable the roots to be spread out at their full length. The soil about the roots of the pot vines should be moderately moist when the plants are about to be turned out. Carefully disentangle the roots, remove any damaged portions by means of a sharp knife, and spread them out as directed in specially prepared soil, making this firm about them. Complete the operation by mulching the border with short litter, and afford enough tepid water to allow the soil to settle firmly about the roots. The canes should be carefully secured to bamboo or other straight stakes, and if undesirably long be disbudded to the desired length, and subsequently, after all danger of bleeding is past, the disbudded portion should be cut off.

The late Peach house.—In order that the trees may not be attacked by aphis when they are in blossom, the structure should be fumigated with the XL-All vaporiser immediately before the flowers expand. A change in the treatment will be necessary as soon as the blossoms commence to open. Careful attention must be given to ventilation, according to the external conditions. A distribution of the pollen should be effected during the warmest part of the day by gently shaking the branches of the trees, or pollination may be performed by some other means, such as dusting the flowers with a rabbit's tail. These precautions, together with a comparatively dry atmosphere in the house, will invariably at this season of the year ensure a free set of fruit. Except during severe frosts in low, damp situations, it will not be necessary to employ artificial heat for this house.

Bananas.—Little skill is required to produce this fruit in perfection in this country, and, except in some large establishments, houses are seldom exclusively devoted to the culture of Bananas. The plants may be satisfactorily grown, and their fruits ripened in an ordinary plant store, or other house of adequate dimensions, commanding plenty of artificial heat. Under such circumstances they have been fruited in these gardens, both when planted out in beds, and with their roots confined in boxes. Suckers readily become established when potted in receptacles suitable to their size and plunged in a brisk heat. When well rooted they may be transferred to their fruiting quarters. It is not necessary to make fresh borders or beds each time, as suitable suckers may be left upon the old stools to take the place of those that have fruited. A suitable compost is loam mixed with decayed manure and leaf-soil or peat. Established plants, and particularly old stools, require frequent applications of liquid manure, and plentiful supplies of tepid water. Musa Cavendishii is a dwarf species, and the most desirable sort to grow for fruiting purposes.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations. *The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, etc., but he cannot be responsible for loss or injury.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editor to see.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matter which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, MARCH 7—
Soc. Franç. d'Hort. de Londres meet. German Gard. Soc. meet. Meeting at Carr's Restaurant, Strand, under the auspices of the British Gardeners' Association.

MONDAY, MARCH 9—
Ann. Meet. United Hort. Ben. and Prov. Soc.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich: 41°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, March 4*: 6 P.M.: Max. 42°; Min 28°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, March 5* (10 A.M.): Bar. 29·9; Temp. 40°; Weather—Fair.
PROVINCES. *Wednesday, March 4*: 6 P.M.: Max. 43° Ireland S.W.; Min 38° Hertford.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—
Sale of Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY AND THURSDAY—
Herbaceous Plants, Lilies, Hardy Bulbs, &c., at 12; Roses at 1.30, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

WEDNESDAY—
Hardy border Plants and Bulbs, Liliums, Gladiolus, &c., at 11.30; Roses and Fruit Trees, at 1.30; Azaleas, Palms, &c., at 5, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

FRIDAY—
Imported and Established Orchids at 12.45, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

Herbaceous Plants.

The recent discussion as to what constitutes a hardy herbaceous perennial should serve a useful purpose by focussing attention on what experience has proved to form a very debatable subject. Our correspondents have clearly emphasised the great divergence of interpretations put upon the term herbaceous, and it cannot be otherwise than satisfactory to have elicited, in the course of friendly controversy, the different views of exhibition judges and others whose opinions are entitled to the fullest consideration.

The whole subject affords an admirable example of the kind of difficulty that lies in the way of framing comprehensive definitions that will stand the test of practical application. When we turn to the best botanical writers who treat of these matters, we find that they have obviously felt the difficulty of the position, and thus they often seem to sound an uncertain note in delimiting their categories. But it is not very difficult to discover, under their reserved expression, the guiding thread that runs through their classifications.

Thus Duchartre, whilst defining the "herbaceous" stem as one that is soft, not firm in texture, and generally green, goes on to add that herbaceous perennials "generally persist only by means of subterranean portions, forming new flowering stems every year." It is quite clear that the texture of the stem was in his judgment the leading feature. The limited duration of the stem commonly, but not necessarily, results from a sappy, non-woody condition of the organ. De Candolle, in his well-known and admirable treatise, *Organographie Végétale*, says that "Herbaceous stems usually persist only for one year, either the whole plant, or the aerial parts of it, dying away." Later on he says that perennial stems are generally of harder texture, and are only herbaceous whilst the shoots are young. De Candolle's statements are of interest as clearly enunciating the principle that annuals are to be regarded as herbaceous plants, which some of our correspondents appear to have doubted.

This is still more explicitly emphasised in Hooker's English edition of Le Maout and Decaisne's *Descriptive and Analytical Botany*. The stem is described as herbaceous when it is "soft and easily broken, such as are annual, biennial, and many perennial stems." Bentham (*Handbook of the British Flora*) at first appears to give some colour to the common definition by describing the herbaceous perennial as one "in which the greater part of the plant dies down after flowering," but inasmuch as he includes in this category all the perennials except those in which "the woody part forms the greater part of the plant," such plants as Pansies, Daisies, and others of similar character, must obviously be included in the herbaceous class we are considering or be altogether disregarded!

But although we may clearly perceive that there is no essential or invariable relation between the herbaceous texture of a stem and the limited period of its duration, the two qualities as a matter of fact are often found to occur together, and it is to this circumstance that the prevailing confusion on the matter is to be attributed. We even find instances where this confusion appears to be reflected in the works of well-known writers, but this probably is due to the fact that the definition is not given as a whole, but occurs partly in one connection and partly in another. Thus Asa Gray describes the herb as a plant with no persistent *woody* stem above ground, and this is perfectly correct. But he goes on to say that it "dies annually, or after flowering, down to the ground at least." Thus the centre of gravity of the definition has, by an odd inversion of the original meaning of the words, come to rest in the deciduous nature rather than the physical texture of the plant. Moreover, this error has become so firmly implanted that, as some of our correspondents have already pointed out, an evergreen foliage has been held to disqualify a plant as herbaceous, and to relegate it to the suffrutescent or suffraticose classes. The difficulties of describing such plants as Primula, Kniphofia, Iris, Saxifrage, Campanula, and Viola, not to mention a host of other examples, as suffrutescent, are so great as hardly to require further comment.

The fact is the definition of herbaceous perennial, as set forth by the leading horticultural authorities in this country—and we are only concerned with our own societies at home—is obviously faulty and ought to be amended rather than maintained merely for the sake of the appearance of stability. Dr. Lindley has well observed, in the preface to his *Vegetable Kingdom*, that it is impossible to "regard perseverance in error [as] commendable for the sake of what is idly called consistency."

The Council of the Royal Horticultural Society, in formulating their *Rules for Judging*, wisely foresaw that some emendations might become necessary as time went on, and they expressly safeguarded themselves against the charge of having irrevocably stereotyped the regulations included in that Code. It is, of course, not desirable that alterations should be made without sufficient reason in a document which carries such weight as does the Code, but we submit that the time has arrived when a radical change in respect of Rules 179 and 180 has become imperative. Those who originally framed the two rules in question plainly entertained doubts as to their general suitability, as is shown by the further recommendations they proceeded to make whereby the very restrictions which subsequent experience has shown to have worked vexatiously might be removed. They suggested that the simple term "hardy flowers" should be employed, and in this way it was hoped that the otherwise inevitable difficulties might be avoided.

But the disadvantage attending the use of the term "hardy flowers" without further qualifications has already been pointed out by several of our correspondents. It is, however, really provided against by the limiting paragraphs which follow the recommendation under Rule 181 of the Code. The exclusion from a class for perennials, of such plants as Wallflowers, Snapdragons, and others which are usually cultivated as biennials, at any rate when grown for exhibition purposes, is sufficiently provided for under Rule 183. But much good would result from the preparation of a list of such doubtful plants as are intended to be definitely excluded under this rule. In the same way it is eminently desirable to frame a list of doubtful plants which are to be excluded from a competition of hardy herbaceous plants, enumerating the species that are intended to be shown only in the shrubby classes. It would not be easy to frame such lists, nor to describe the limits which will determine the position of many of those that require specially defining. But possibly a collaboration on the part of the Scientific and Floral Committees of the Royal Horticultural Society might be able satisfactorily to settle the class of the doubtful claimants to the rank of herbaceous perennials.

It may, however, be pointed out that many of the practical difficulties that have come under our own observation have been caused by the tendency on the part of those who were called upon to officiate as judges to place artificial limitations on the terms employed in the schedule.

For instance, we have a letter on our table from an exhibitor at a provincial flower show held last August who competed in a class for a "bouquet of hardy garden flowers." He included Sweet Peas in his exhibit, and subsequently the judges wrote upon

his card, "Peas not hardy flowers." So far as it is possible to follow the reason that led the judges to take such an erroneous view, it would appear to rest on the fact that Peas are annuals, but how can it be claimed that they are not hardy, and on what grounds were annuals excluded when the schedule contained no hint as to whether annual, biennial, or perennial plants were intended for that particular class? In every such case judges should interpret the schedule liberally, and refuse to disqualify an exhibit when the circumstances do not actually compel them to do so. In judging a class for "hardy flowers" when the schedule contains no limitations or exclusions, it would be incorrect to disqualify bulbous or tuberous plants, herbaceous plants, or even flowers cut from a Horse Chestnut tree, the only requirement being that the plant is ordinarily capable of growing out of doors from year to year without protection. The class for "herbaceous perennials" may include any perennial plant that does not form woody stems; and bulbous or tuberous species should not be disqualified unless they are definitely excluded by words inserted in the schedule. In like manner the words employed by another Society, "hardy herbaceous plants," without any qualification, obviously do not exclude annual, biennial, or perennial plants, even if the latter should be bulbous or tuberous species; the only qualities insisted upon are those of hardiness and freedom from woody stems. If the term "herbaceous plants" be used alone, then it would include species from the hot-house equally with those from the open garden. All these and similar cases may appear perfectly simple, but that they are frequently adjudicated upon in an unsatisfactory manner is proved by letters we have received from exhibitors who have suffered unjustifiable disqualification in the competitions.

ADDITIONS TO THE KEW HERBARIUM DURING 1907.—We learn from the *Bulletin of Miscellaneous Information*, Kew, that during last year over 12,000 sheets were presented or sent in exchange to the Herbarium by about 120 persons and institutions, while over 7,000 sheets were purchased.

MR. GEORGE P. MILN.—The Council of the Chester Paxton Society has awarded the Gold Medal of the Society to Mr. G. P. MILN, the honorary secretary and treasurer. Mr. MILN is a most capable organiser, and he has initiated and carried to a successful issue many important schemes for the improvement of the local exhibitions of fruits and flowers. He has also gathered around him a band of practical men who have done much to improve the cultivation of hardy fruits and other branches of horticulture. He has done excellent work in connection with the flora of Cheshire, especially with regard to the Gramineæ; and for his services to science the Chester Society of Natural Science, to which he has also acted as honorary secretary for the last 20 years, awarded him a few years ago the Kingsley Memorial Medal. The gold medal of the Chester Paxton Society was presented on the occasion of the annual dinner of the society held on February 22, which the members and guests attended at the invitation of the president of the society, Mr. A. W. ARMSTRONG. The presentation was made by the founder of the society, Mr. J. D. SIDDALL, who in the course of his remarks eulogised Mr. MILN's labours on behalf of the society, and in support of his testimony he quoted figures shewing the rapid progress made by the society since 1891. In 1907 the amount of prize-money offered in the schedule was: Fruit classes, £48 12s.; Chrysanthemum classes, £42 17s. 6d.; total, £90 19s. 6d. In 1891 the figures were: Fruit classes, £20; Chrysanthemum classes, £8; total, £28. The number of subscribers last year was 311, but in 1891 they were only 80. There had also been a great increase in the merit of the individual exhibits, and all this was largely due to the work of Mr. MILN. The gold medal is inscribed: "To G. P. MILN, in recognition of services rendered as Hon. Secretary and Treasurer, February 8, 1908."

BRITISH GARDENERS' ASSOCIATION.—We are informed that a public meeting will be held at Carr's Restaurant, Strand, on Saturday, March 7, at 7 p.m. Mr. GEORGE GORDON will preside on this occasion, and an address will be delivered by Mr. JNO. WEATHERS, secretary of the Association.

THE SURVEYORS' INSTITUTION. The next ordinary general meeting will be held on Monday, March 9, at 8 o'clock p.m., when the adjourned discussion on the paper read by Mr. W. G. S. ROLLESTON on "The Small Holdings and Allotments Act, 1907," will be resumed.

PORTRAIT OF DR. D. H. SCOTT, F.R.S. The Jodrell Laboratory of the Royal Gardens, Kew, was the scene of an interesting ceremony on the afternoon of February 29. The occasion was that of handing over to the custody of Col. PRAIN, the Director of Kew, a portrait of Dr. D. H. SCOTT, F.R.S., who for nearly 10 years was the Honorary Keeper of the Laboratory. Dr. SCOTT retired from this office a little more than two years ago, but during his tenure of the post the Laboratory became widely recognised as a place from which were issued many important results of botanical investigations carried on by himself and by other workers there. It was a happy idea to commemorate Dr. SCOTT's connection with the Laboratory by placing his portrait in the building the value of which he has done so much to enhance. It was from the first decided that the subscribers should be limited to those who had at some time or another actually worked in the Laboratory, and this plan has been steadily adhered to. Thus the gathering which took place last week possessed a real significance in the history of this department of the establishment at Kew. Professor A. W. OLIVER, who presided at the meeting, opened the proceedings with a sketch of the botanical activities of the subject of the portrait, and Professor F. O. BOWER followed with an account of the work of the Laboratory. Other speakers were Mr. WALTER GARDINER and Mr. GWYNNE VAUGHAN. Col. PRAIN, in accepting the portrait, which is to be hung in the Laboratory, adverted to the loss caused by the retirement of Dr. SCOTT, but hoped that the occasion might be regarded as a good augury for the future success of the institution. Dr. SCOTT replied in an interesting and humorously reminiscent speech.

NATAL BOTANIC GARDENS.—We are informed that the Natal Government have found themselves obliged to reduce the expenditure upon the Natal Botanic Gardens and the Herbarium. The grant to the Herbarium has been taken away entirely, whilst the grant to the gardens has been reduced from £350 to £150. This action has necessitated the discharge of two of the assistants and a considerable reduction in the salaries of the director and his curators. It is difficult to see how the important work of the department can be carried on effectively under these straitened circumstances. *Kew Bulletin*, No. 2, 1908.

ANNUAL DINNER OF NURSERY EMPLOYEES.—About 30 of the employees of the firm of Messrs. R. B. LAIRD & SONS, Limited, held their first annual dinner in BISSET'S Rooms, Haymarket, Edinburgh, on Friday evening, the 28th ult., under the presidency of Mr. ROBERT LAIRD, managing director, to whose efforts the staff was indebted for a most enjoyable evening.

PRESENTATION TO MR. DAVIS.—On February 28 the gardeners at Hall Place, Tonbridge, made a presentation to the head gardener, Mr. DAVIS, on his retiring after 37 years' service.

TRAPS FOR ANTS.—Writing in our contemporary, *Revue de l'horticulture* (Belgium), Mons. I. WYSELLE describes a simple and ingenious method of getting rid of these pests. He wetted sponges with sugary water, and placed them near the nests. The ants were attracted in large numbers, and crowded into the sponges. They were afterwards killed by plunging the sponges into hot water, and by repeating the process several times the nuisance was overcome. It is perhaps not likely that all the ants would be caught in this way, as some would not leave the nests, but the method deserves a trial, as at any rate the numbers could be kept down in cases where for various reasons it might be impossible to exterminate them in other ways. Ants, however, are sometimes credited with more damage than they deserve. We have seen a fine patch of Potentilla nitida, growing on a rock-garden, not only none the worse for, but actually improved by, their presence. The young shoots rooted freely in the powdery earth which they excavated when making their nests, and the plant was incomparably more flourishing than a number of others which were not infested, but otherwise were growing in the same garden under apparently similar conditions.

***THE AGRICULTURAL HOLDINGS ACT, 1906.** Mr. G. A. JOHNSTON'S book on this subject has not taken long to secure the honour of a second edition. Though perhaps somewhat too technical for the reader untrained in legal procedure, the volume must prove of considerable utility at the present time to those upon whom the duty falls of preparing or approving leases of agricultural holdings (a term which, by the way, has not yet been extended by the Government to include nursery grounds) while bearing in mind the changes which will occur when the Act of 1906 comes into force on January 1 next. The various Agricultural Holdings Acts are brought together in a form very handy for reference by the practitioner, and the clauses which will stand repealed after the present year are usefully distinguished by small type. We trust the author may not think us ungrateful if we express the hope that the long-promised Consolidation Bill, codifying the Statutes on this subject, may soon render obsolete this part of the volume. The Act of 1906 (known at the time as the Land Tenure Bill) was so altered during its passage through Parliament that it contains many faults for which the original draftsman cannot justly be held responsible, but the ultimate result proves the inconvenience of the increasing tendency to graft new legislation on to earlier Acts of Parliament. The Appendix to the present edition of the book under notice is greatly strengthened by the inclusion of the Board of Agriculture Rules and County Court Rules of procedure and forms. The comments on the clauses of the new Act deserve careful perusal, those which deal with the present-day tendency towards fixity of tenure being especially worthy of notice by students of modern legislative methods as well as by landlords and their agents.

---

* *The Agricultural Holdings Act, 1906.* By G. A. Johnston,

CALCIUM CYANAMIDE.—This nitrogenous fertiliser, which is being manufactured on a somewhat extensive scale on the Continent, has several times formed the subject of enquiry on the part of our correspondents. We note with much pleasure therefore that Mr. A. D. HALL, Director of the Experimental Station at Rothamsted, has published the results of his investigations on the manurial and keeping qualities of calcium cyanamide in the current number of the *Journal of the Board of Agriculture*. As the substance is made from calcium carbide, which, as is well known, yields the poisonous and inflammable acetylene gas when it is moistened with water, it is satisfactory to learn that the amount of carbide actually present is so small as to be quite negligible from the point of view of safety. Further, the cyanamide keeps well, and, under the ordinary conditions of storage loses very little of its manurial value. One of its chief drawbacks is the very fine powdery state in which it is sent out, which renders it troublesome to sow on the land, whilst it was not clear whether it could be mixed with other fertilisers without damage either to them or to itself from the manurial point of view. The Rothamsted experiments, however, prove that it can be mixed with super-phosphate, and in this form it can be more easily applied to the land. The acid super-phosphate is converted into the di-calcium phosphate, and this, although slower in its action than the super-phosphate, is still available in the soil as plant-food.

THE ORIGIN OF THE POTATO.

ON February 20, at a meeting of the Linnean Society, Mr. Arthur W. Sutton read an interesting paper on this subject, illustrated by numerous lantern slides, showing the peculiarities of various species of tuber-bearing Solanums which had formed the material for experiments extending over more than 20 years. These experiments were made with the twofold object of determining the question as to which wild species had yielded the Potato of commerce known as S. tuberosum; and, having discovered this, to reinforce, if possible, the resistant powers of the commercial Potato against disease by the infusion of a stronger strain. The records relating to the cultivated Potato go back

FIG. 61.—SOLANUM COMMERSONII.

to the 12th century, and the plant has consequently become so modified by selection that the task of discovering which of the wild, tuberiferous species formed its starting point has become a very difficult one; all the illustrations available, and even the nomenclature of S. tuberosum, obviously referring to the modified cultivated forms and not to a wild species. In 1883, at the suggestion of Lord Cathcart, who had been impressed by the great annual loss suffered through the Potato disease, Mr. J. G. Baker made an exhaustive study of the various species of tuber-bearing Solanums, with the above-mentioned object in view. The results of his investigations were

FIG. 62.—SOLANUM TUBEROSUM, PAULSEN'S BLUE GIANT.

read at a meeting of the Linnean Society held on January 17, 1884. At that time it was thought that S. Maglia (Schlecht.), commonly known as Darwin's Potato (see fig. 66), was most likely to yield the best results, as it was itself a native of the low-lying, swampy soils of the Chonos Archipelago, and therefore might be expected to be able to withstand the disease from which the cultivated Potato suffers when it is exposed to damp conditions. Mr. Sutton followed up Mr. Baker's researches by attempting crosses between S. Maglia and S. tuberosum, i.e., the Potato of commerce, but only succeeded in obtaining one hybrid which, after 20 years' cultivation, has yielded nothing equal in value to existing commercial Potatos. Fig. 66 represents S. Maglia from Mr. W. G. Smith's drawings of S. Maglia as grown in Reading trial ground, showing bifid stigma, pollen grains, &c. This species may therefore be regarded as a negligible factor in the evolution of the cultivated Potato or in the improvement of it as far as disease-resisting qualities are concerned. Various attempts were made with other species, viz., S. Jamesii, S. Fendleri, and S. Ohrondii, the last of which Mr. Baker considers to be identical with S. Commersonii (Dunal), but no results of any value were obtained, and further efforts in this direction were consequently abandoned. In 1901 Mr. Sutton was surprised to see in the French journals that S. Commersonii, a perfectly wild and constant species, was reported by Monsieur J. Labergerie, of Verrières in France, to have suddenly produced by a bud-sport a Potato which on examination seemed to be of the most developed cultivated type. The specimens subsequently offered under the name of S. Commersonii "Violet" (Labergerie) undoubtedly answered to that description. Potato experts, however, could not admit this supposed origin without further proof, since no other instance had hitherto been known of a new variety of cultivated Potato arising except from seed. Bud-sports do not occur in this connection, or, at any rate, they are not sufficiently authenticated. Thus, most botanists regarded it with scepticism, since the so-called "mutation" presented all the specific characters of S. tuberosum and none of S. Commersonii, which is opposed to the recognised nature of any "sport." Still greater doubt arose when it was found that the so-called S. Commersonii "Violet" (Labergerie) seemed absolutely identical, even in microscopic detail, with a well-known and widely-distributed Potato known as the "Blue Giant," and it may be presumed that a tuber, or portion of one bearing a bud, was accidentally present in the soil in which the S. Commersonii tubers of M. Labergerie were grown, and that this in due course asserted itself among them. Fig. 61 represents Mr. W. G. Smith's drawing of wild type of S. Commersonii, showing cordiform berries, pollen grains, &c. Fig. 62 is taken from his drawing of "Blue Giant," and shows round seed berry, pollen grains, &c., whilst fig. 63 illustrates Labergerie's so-called mutation S. Commersonii "Violet," with round seed berry, pollen grains, &c. From a study of these figures it will be observed that the pollen grains of the type Solanum Commersonii are of a true elliptical form, whereas the pollen grains of the Blue Giant Potato, like the pollen grains of all other cultivated Potatos, are perfectly distinct from those of the wild type, being of a very irregular and broken form, and the pollen grains of Labergerie's so-called mutation correspond in every detail with those of the Blue Giant. This point is more fully brought out in fig. 64, where the pollen grains in question are shown in the bottom row. This case has already been so thoroughly discussed, that I merely allude to it here as having formed the incentive for further research on Mr. Sutton's part, and this time, fortunately, with results which promise to be of great value. It is, however, to be noted that these results have not been reached by hybridizing, but rather by close observation of the several species of tuber-bearing Potatos in Mr. Sutton's collection. One result of the experiments has been the discovery that in every case where the truly wild nature of a species was determined, the offspring invariably came perfectly true to the parental type, as correlated with this, the pollen grains were all evenly elliptical and uniform in size.

With cultivated Potatos, on the contrary, the offspring from seed are invariably very diverse in size, shape, and colour, while the pollen grains, as already mentioned, are, with one exception (a cultivated Potato extensively grown in the Andes, and, unlike any European Potato),

FIG. 63.—SOLANUM COMMERSONII, VIOLET (LABERGERIE).

very irregular in shape and size, and never truly elliptical. Fig. 64 represents pollen grains of several wild types magnified 600 diameters, contrasting with pollen grains of "Blue Giant" and Labergerie's so-called mutation. There are therefore two characters in S. tuberosum, i.e.,

the Potato of commerce which, apart from specific differences in foliage and flower, distinguish it from all known wild types; these are diversity of offspring and modification of the pollen grains.

Mr. Sutton's numerous slides depicted several species of Solanum, and variants of S. tuberosum received from Mexico and elsewhere, all of

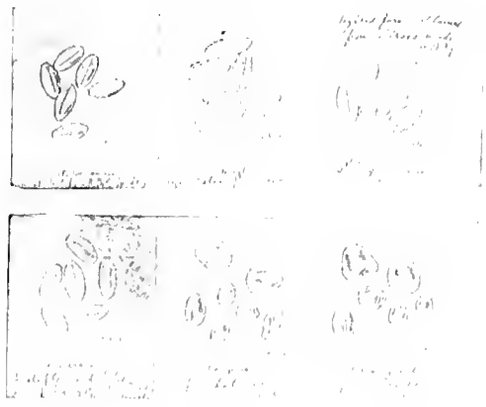

Fig. 64.—pollen grains of species and varieties of potatos.

Top row: S. etuberosum, S. Maglia, and S. Maglia × cultivated Potato.

Bottom row: S. Commersonii, wild type S. Commersonii violet, and Paulsen's Blue Giant.

which, however, are of secondary interest as compared with S. etuberosum Lindley, to which so far I have not alluded. The species was received some 20 years ago by Mr. Sutton from the Edinburgh Botanic Gardens as a wild one of Chilian origin. It is, despite its name, etuberosum, meaning non-tuber-bearing, certainly the nearest approach as a wild species to S. tuberosum as cultivated, since though it differs in habit, and has hairy foliage and also purely elliptical pollen grains, it produces edible tubers, and these, in the course of 20 years, have increased under cultivation from less than an inch in diameter to a fair marketable size, while in flavour they cannot be distinguished from ordinary ones. Fig. 65 represents Mr. W. G. Smith's drawing of S. etuberosum as grown at Reading, with pollen grains, spotted seed berries, tubers, &c. The specific characters are sufficiently marked to differentiate the type S. etuberosum clearly from our cultivated Potato, despite its points of agreement. Like other wild types under cultivation, S. etuberosum is extremely shy in producing seed; flowers and pollen may be plentiful enough, but after 20 years' cultivation at Reading it was only in 1906 that a single seed berry was obtained, and thus the first opportunity is afforded of testing its capacity as a wild species of producing true progeny. Mr. Sutton was surprised to find that of the 20 plants which were raised from seed, not one was exactly a replica of the parental form, although several showed distinct S. etuberosum character. Indeed, the whole batch, both in haulm and tuber, exhibited a degree of diversity such as might have sprung from the seed of the ordinary cultivated Potato. This variability extended to size, colour, and every other character; in some cases, indeed, the tubers were already of marketable size. In one instance only did any of the seedlings differ materially from the seedlings of the commercial Potato, and the tubers of this plant were not only deep purple in skin, but the flesh was also of the same deep purple colour, corresponding in this respect with one of the cultivated types of potato grown in Chili. A curious feature in S. etuberosum is that the seed berries are prettily spotted (see fig. 65). This diversity raises the question whether S. etuberosum is really a true species, or whether it is merely another example of introduced tubers derived from cultivated strays, such as have been received from time to time from S. and N. America (Mexico) ostensibly as wild plants. That the diversity of the Reading seedlings is due to cross-fertilisation Mr. Sutton does not consider likely, as in his experience this rarely occurs, and the seed capsule was found in the centre of a large number of S. etuberosum plants. It is noteworthy that all the other wild types which reproduced themselves pure from seed had an equal chance of being cross-fertilised. Happily, attention having now been concentrated on S. etuberosum, both self-fertilisation and cross-fertilisation have resulted in further seed supplies from the type and from some of its diverse offspring, and it is especially important to note that the pollen of the one seedling plant examined was of the true, wild, elliptical form. With this fresh material, it is hoped that light may be thrown on the origin of S. etuberosum on Mendelian lines in the coming season. Perhaps, however, the most noteworthy fact in connection with S. etuberosum, and certainly the most important from an economical point of view, is that in it we have a promise of the attainment of the primary object of the research suggested by Lord Cathcart and commenced by Mr. J. G. Baker, viz., the production of a really disease-resisting Potato. For 20 years S. etuberosum has been grown in experimental grounds at Reading, surrounded for comparison by varieties of the Potato of commerce, many of which season after season have been more or less subject to the disease Phytophthora infestans. Despite this, there has never been the least sign of this disease either on haulm or tuber of S. etuberosum, so that a score of years of cultivation have failed to affect its resistance to the pest. *Chas. T. Druery, V.M.H., F.L.S.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

The Proposed Vegetable Exhibition.—I can assure *Onlooker* it is a great relief to my mind, as I am sure it will be to many others, to be assured that the Potato will be well looked after without the aid of the defunct National Potato Society. I am quite sure *Onlooker* does not wish to misconstrue the meaning of the paragraph relating to varieties for certain dis-

Fig. 65.—solanum etuberosum.

tricts. I did not mean to infer, neither did I say that one Potato only is suited for a certain district; my actual words were: "No doubt five or six varieties would be ample in *Onlooker's* locality, but I doubt very much if those same varieties, which, in his opinion, are the best, would be as popular in other parts of the country. Even one of the three varieties named by him, viz., Windsor Castle, one of the finest Potatos ever raised, I have known to fail lamentably in many localities. With regard to the wrong naming of other kinds of vegetables, if I made the assertion that varieties were wrongly named to deceive the judges and public, I venture to say I should have the courage of my conviction. What I contend, and always have done, is that vegetables do not receive the

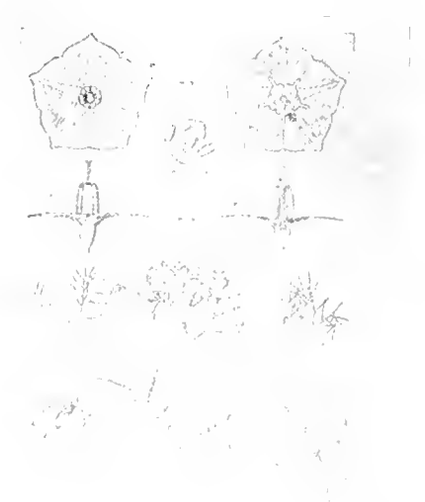

Fig. 66.—solanum maglia.

encouragement they deserve. What has given a stimulus to nearly every trade or profession, but the influence of exhibitions and competitions? *Onlooker* asks why the Vegetable Show at Vincent Square was not a success. I can tell him why, for the same reason that the show of table decorations failed, viz., insufficient encouragement by way of prizes. Was there any more attractive exhibit at the R.H.S. annual meeting than the Potatos exhibited by Messrs. Sutton & Sons, or did anything receive so much attention from the general public as this exhibit? *E. Beckett.*

——With respect to the objection to London vegetable exhibitions on the ground that no one will visit them, I would like to know what chances the public have had to see them? When collections of vegetables are exhibited at the Temple shows visitors crowd over them so greatly it is difficult to inspect the produce. When there were vegetable competitions at the old Royal Aquarium they attracted crowds to see them. If few went to see the vegetable exhibition at Chiswick in 1903, is it not true that no exhibition of any nature has attracted many visitors to Chiswick for a number of years past? The attendance at the Horticultural Hall show a few years ago may have been small, but what chance had the public to learn of its existence? Let the Royal Horticultural Society but make an annual vegetable exhibition at Vincent Square a regular feature in its programme, as it does with fruit, then the attendances will be satisfactory. *A. D.*

Herbaceous Plants.—For perhaps the twentieth time in my life I find gardeners discussing the word "herbaceous." Isn't it sufficient to say herbs? annual, perennial, hardy, tender, tuberous, bulbous, conuous, aquatic, pot-herbs; or what not? Surely no one could mistake plants so described. The definition "a plant producing annual flowering stems from a perennial root-stock" is fallacious. In the sub-tropics many herbs are perennial bloomers. *James MacPherson, Trenton, N.T., U.S.A.*

Rust on Chrysanthemums.—My experience is that the rust fungus can be destroyed without pinching the leaves, as Mr. Lunt advised on p. 70. Before taking the small plants out of the propagating case, prepare a staging for them to also hold a layer of ashes, which should be given a dusting of soot, then damped down with a rose can. If this system is persevered with all along through the season, the rust will not thrive. I have seen bad cases cured with this simple treatment. *C. Vickers.*

THE GUNNERAS.—I am pleased to observe Mr. Bartlett's note in your issue for February 29. The Gunneras are considerably hardier than many imagine them to be, and both G. manicata and G. scabra succeed perfectly in many gardens north of the Tweed, although in comparatively mild districts, where they will succeed well in sheltered places, they are occasionally killed by late frosts if the foliage has begun to unfold, and the plants are in a position where cold draughts of wind strike fully upon them. Hence the desirability of protection. There are many plants considered much hardier than the Gunneras which will succumb under these conditions. At one time I thought that G. manicata was more tender than G. scabra, but longer experience and observation have modified this opinion, and I believe that G. manicata is as hardy as the other species. I think, however, that the little G. magellanica is more tender than either, and I do not recollect having seen it in northern gardens where it has stood over several winters. I have lost species twice from spring frosts, and I know several gardens where it has been destroyed from the same cause. Regarding the size of the leaves of Gunnera manicata to which I referred in my note in your issue of February 15, I may say that these leaves, 9 feet in diameter, were only produced by the most liberal feeding. I am speaking from memory when I say that the finest examples I have seen are such as received a most liberal supply of manure, this amounting to three cartloads of good farmyard manure annually. Mr. Bartlett is correct in saying that the best plants are obtained when cultivated in a moist position, but not in a bog; plants of Gunnera manicata by the waterside should be a little above the level, and in such a position that, while the roots can reach the moisture, the crowns are well above it. This is a common necessity with many moisture-loving plants, but it is not a point which is sufficiently studied by those who are planting them. *S. Arnott.*

A SUSSEX WASTE.—Mr Leslie Wood states that the land under discussion is *not clay*, but "practically all sand." I refer him to the Geological Map and Survey of Sussex, and to the *Encyclopædia Britannica* for a reply, where he will see that about two-thirds of the county consists of almost pure chalk, and that the next greatest tract is what is called the "Forest Ridge," where the "waste" is, consisting almost throughout, of the stiff Wealdon clay, "occupying nearly all the inland district of Sussex." The clay is so good and extensive that brick-making is the chief industry, there being about 1,500 brick factories in the locality. I know what this clay is like, for I have had to plant in it on estates wide apart, but on the same formation, and have, in every case, had the greatest difficulty to find a spot suitable for a home nursery, the clay being so stiff as to render the planting of young seedling forest trees almost impossible until heavy dressings of leafmould from the wood, or light garden refuse had been added to make the clay workable. I expect to be near East Grinstead next month, and I think I could find Mr. Leslie Wood one day's stiff exercise, at least, in pulling his legs out of the clay, and show him a portion of the county he does not appear ever to have seen before, although situated at his door. *J. Simpson.*

LILIUM GIGANTEUM.—Unlike the famous "Indian Lilies" described in a recent issue of the *Gardeners' Chronicle*, this great Lily, which is a native of the lower slopes of the Himalayas, is equally adapted for conservatory or open-air cultivation. It is also one of the very few Lilies that not only endure, but are greatly benefited by a strong mulching of stable manure. It is the opinion of my friend, Mr. McDonall, of Logan, in this parish, who has grown it, like myself, for many years—though somewhat more extensively—that, without this effective manurial application it gradually degenerates into considerably smaller and more impotent bulbs. This fact, which I feel certain cannot be questioned, is the key to its continued successful cultivation. It is well grown at Monreith in this county by Sir Herbert Maxwell, who might perhaps give us his experience of this unique Lily in some future issue of the *Gardeners' Chronicle*. I have had Lilium giganteum in my own garden over 10 feet high, and bearing nearly a dozen of its ivory-white, violet-stained, intensely-fragrant, funnel-shaped flowers. The most impressive specimen of this great Indian Lily of which I have ever heard, was one that reached in Cavens Garden, Kirkbean, Kirkcudbrightshire (where its cultivation is made by the head gardener a kind of specialty), the enormous height of 14 feet. It quite overtopped the lofty garden-wall, and was the admiration and wonder of all beholders. Lilium giganteum is occasionally grown by enthusiasts from seed, which it produces in great abundance; but it is much more frequently propagated from offsets, when the immense bulb—which usually takes four years for its development—has become exhausted in the production of the flowering stem. *David R. Williamson*

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 3.—The meeting of the Committees held on Tuesday last was after an interval of three weeks. It was therefore anticipated that a good display of flowers would be staged. This belief was fully justified, for the display was one of the best ever seen in the Hall. There were no fewer than three Gold Medals awarded, which is in itself significant of the quality of the exhibition. It was generally remarked that, probably, never before have two such fine displays of Orchids been seen at these exhibitions as those exhibited by Major HOLFORD and Sir JEREMIAH COLMAN, Bart.: whilst the displays of forced flowering shrubs and plants were deserving of praise. The attendance was large, and at times the number of visitors was so great that it was difficult to make an inspection of the exhibits. At the afternoon meeting 110 new Fellows were elected, and a lecture on "Bulbous Plants in New Zealand" was delivered by Mr. E. White.

Floral Committee.

Present: W. Marshall, Esq. (chairman), and Messrs. Henry B. May, W. A. Bilney, Jas. Walker, Jas. Douglas, T. W. Turner, G. Reuthe, Jno. Green, J. F. McLeod, W. Howe, J. Jennings, C. J. Salter, W. Bain, Chas. Dixon, E. J. Cook, R. C. Reynolds Nevill, Herbert J. Cutbush, Arthur Turner, R. C. Notcutt, W. P. Thomson, E. H. Jenkins, W. J. James, Geo. Paul, R. Hooper Pearson, J. W. Barr, C. R. Fiebler, C. T. Druery, Geo. Gordon, W. Cuthbertson, and Rev. Page Roberts.

A fine display was made with flowering bulbs by Lady TATE, Park Hill Gardens, Streatham Common (gr. Mr. W. Howe). There were included among the plants shown Tulip American Lac (pink and yellow—a striking blend of colouring), the white Joost van Vondel, Rose Grisde-lin, Unique (yellow and white), Grace Darling (scarlet), Thomas Moore (orange and scarlet), &c. Other subjects were Narcissi Victoria, Henry Irving, Golden Spur; Lilium longiflorum, Solomon's Seal, Callas, and Roman Hyacinths. The whole was relieved with small plants of Azalea and Bamboos. (Silver-Gilt Lindley Medal.)

Messrs. J. HILL & SON, Barrowfield Nurseries, Lower Edmonton, showed a large number of the finer exotic Ferns in capital examples. There were large plants of Asplenium caudatum, of Davallia tenuifolia Veitchii, Pteris Childsii, Adiantum Capillus Veneris imbricata, shown on a pillar in pockets of cork, Lomaria gibba, Gymnogramma elegantissima, Polypodium conjugatum, Adiantum Bausei, and several other small-growing species. (Silver-Gilt Flora Medal.)

Messrs. R. & G. CUTHBERT, Nurserymen, Southgate, exhibited many forced plants of large and small sizes, all wonderfully bloomed. Varieties of Azalea mollis were intense in their colours. Lilacs were abundantly flowered, but the plants, in some cases, were not distinguished by good forms. Plants of Magnolia speciosa were well bloomed. The arrangement adopted of placing dwarf beds of Azalea mollis between groups of taller plants enabled patches of bright colours to be formed that were superior in effect to the system ordinarily adopted in staging groups of similar plants. (Gold Medal.)

A fine display of hardy forced plants was also made by Mr. L. R. RUSSELL, nurseryman, Richmond. The plants employed in forming the large group were Azalea indica, A. mollis, Lilac (especially fine being the white-flowered Marie Legraye), Clematis indivisa lobata, and Buddleia asiatica. (Silver Flora Medal.)

Messrs. H. B. MAY & SONS, The Nurseries, Upper Edmonton, exhibited Ferns in moderate number, the finer specimens being Nephrolepis todeoides, Pteris Childsii, Davallia solida, Lomaria platyptera, &c. Other plants were interspersed amongst the Ferns. We noticed the scented-leaved Pelargonium Clorinda, having rosy-red blooms in trusses; Clematis indivisa lobata; Primula × kewensis, and P. obconica. (Silver Flora Medal.)

Messrs. W. CUTBUSH & SONS, Highgate and Barnet, made a big floral display with hardy forced plants. The principal subjects in the group were Wistaria sinensis, Indian Azaleas in variety, Lilac with white and coloured flowers, Rhododendrons, Ledums, Pyrus japonica, Daphne chrysantha, Kalmia glauca, a quantity of Hepaticas, Dielytra spectabilis, Ericas, &c. In another part of the Hall Messrs. CUTBUSH showed many varieties of tree Carnations as cut flowers. (Silver-Gilt Flora Medal.)

Messrs. H. CANNELL & SONS, Swanley, Kent, made a large display of bright colour with Zonal Pelargoniums, and with blooms of Primula sinensis of almost every tint. There were other plants of Primulas of the stellate type, and these also were in many colours and shades. The plants were profusely flowered, and, consequently, of a highly decorative character. (Bronze Flora Medal.)

Messrs. HUGH LOW & Co. showed a group of greenhouse Acacias in bloom, including A. armata, a species not often observed in bloom when in a small stage of growth, the pretty A. cordata, A. magnifica, &c. The firm also showed on an adjoining table their Cyclamen, Low's Salmon, to which an Award was recently made. These were in company with other varieties of this useful greenhouse subject, with Grevillea alpina, Lachenalias, Daphne indica rubra, &c. The display was edged with the hanging shoots of Lotus peliorhynchus, although not in flower. This firm completed their group with a meritorious group of Carnations of the winter-flowering type. (Silver Flora Medal.)

Messrs. JAMES VEITCH & SONS, LTD., King's Road, Chelsea, had a most interesting array of greenhouse flowering plants, arranged on the table they usually occupy at these meetings. The brightest of all these plants was the beautiful Coleus thyrsoides, exhibited in a batch of a dozen or more plants. Another splash of colour was provided by densely-flowered plants of greenhouse Azaleas, specially fine being the varieties Apollo, Empress of India, Sir J. T. D. Llewelyn, and the dwarf-habited "Hexe," the last-named being in 3-inch pots, Coreopsis Grantii, Lopezia miniata, Primula × kewensis, Kalanchoe Dyeri (very fine as shown), and a batch of pot plants of American Carnations with foliage, &c., furnished the remainder of the group. (Silver-Gilt Flora Medal.)

Messrs. W. PAUL & SON, Waltham Cross, Herts., filled one corner of the hall with a group of Camellias, having both pot plants and cut flowers. This firm are prominent cultivators of this old subject, which has so largely gone out of favour of recent years. The exhibit contained most of the best varieties in season, and there were several kinds of Messrs. PAUL's raising. The largest plants were arranged under the wall, the best noticed being Contessa de Hainant (blush rose); Adelina Benvenuti, very similar in colour to the preceding; alba plena, still unsurpassed amongst the white varieties; Mars, a semi-double variety of a red colour; Marchioness of Exeter (pink), and Mad. d'Offory (white). There were cut sprays of many other kinds displayed in baskets, and the inclusion of several well-flowered plants of Clematis indivisa lobata added an additional interest to the exhibit. (Silver Flora Medal.)

Messrs R. VEITCH & SON, Exeter, displayed sprays of interesting shrubs, trusses of Rhododendron flowers, and hardy Heaths. A branch of Cotoneaster angustifolia was exhibited in fruit. Berberis Bealii was freely flowering, as was a branch of the pretty Andromeda japonica.

Mr. R. GILL, Nurseryman, Tremough, Penryn, Cornwall, showed a collection of Rhododendron flowers, all of which were taken from plants growing in the open. A new variety of the R. arboreum type, named Mr. Henry Shilson, has large rose-coloured flowers set in a huge truss. Other fine trusses were those of R. barbatum, R. arboreum album, and hybrids of this species: R. Harrisii, and the variety Duke of Cornwall.

Guernsey-grown Carnations were displayed by Mr. H. BURNETT, of that island. He exhibited some choice blooms of such notable varieties as White Perfection, Mrs. H. Burnett (soft salmon-pink), Enchantress, Britannia, &c., the whole being relieved with trails of Asparagus Sprengeri and Smilax.

Another exhibit of these popular flowers was presented by Mr. W. H. PAGE, Tangley Nurseries, Hampton, who used a setting of Adiantum Ferns and vases of Liliums for their better display. (Bronze Flora Medal.)

Mr. GEO. MOUNT, Rose Nurseries, Canterbury, exhibited the new Rose Joseph Lowe, a variety shown by Messrs. LOWE & SHAW, LTD., Uxbridge, at the last Holland House exhibition. Mr. MOUNT also showed the new H. T. Richmond in well-developed blooms. (Silver Flora Medal.)

Lord ZOUCHE (gr. Mr. Spillard) showed a number of well-cultivated plants of Cyclamen latifolium in 9-inch pots.

Messrs. PAUL & SON, The Old Nurseries, Cheshunt, showed forced Lilac, Primula obconica gigantea, P. × kewensis, and a few Alpine plants, including the single red-flowered Hepatica and the prettier single-flowered blue species, also Hellebores and early-flowering Irises. (Bronze Flora Medal.)

Messrs. JOHN PEED & SONS, West Norwood Nurseries, exhibited Cacti, Agaves, Saxifragas, hardy Primroses and Hepaticas, together with a large batch of plants of Lachenalia Nelsonii, L. Rector of Cawston, L. aurea, L. luteola, and L. Cammii.

Mr. G. REUTHE, Hardy Plant Nursery, Keston, Kent, showed miscellaneous hardy plants and Alpines, Hepaticas, Saxifragas, Cyclamens, Primulas, various bulbs, Irises, Corydalis, Eranthis cilicica, species of Crocus, and a quantity of Rhododendron flowers. (Bronze Flora Medal.)

The GUILDFORD HARDY PLANT NURSERY, Guildford, showed Alpine and other hardy plants of an herbaceous nature. We noticed a fine array of the pretty Anemone blanda, another of Iris reticulata, Omphalodes verna, Megasea cordifolia, hardy Heaths, &c.

Messrs. R. WALLACE & Co., Kilnfield Nurseries, Colchester, also showed some pretty members of the Alpine and herbaceous sections plants which meet with greater favour each year. The specialities shown by Messrs. WALLACE included Crocuses in variety, Irises, of which we may mention a fine exhibit of Iris Danfordiæ, having yellow flowers on short peduncles; Adonis amurensis, Saxifraga burseriana major, and a host of other pretty flowering subjects.

Some splendid vases of Lily of the Valley were exhibited by Mr. ROBERT SYDENHAM, Birmingham, as growing in fibre without provision for drainage. There were also Tulips, Narcissus, and Hyacinths, all in the same excellence of health and freedom of flowering, grown in the same manner, the pots being handsome, glazed receptacles, with a green exterior. This system of bulb culture is to be recommended for plants intended for room decoration.

Messrs. HEATH & SON, Cheltenham, showed a selected strain of Primula × kewensis, together with its parents. They had also a row of a variety of the old florists' Primula named Rose Queen, a name significant of its colouring. There were also star or stellata Primulas, and a few rare Alpine plants.

The Misses E. & M. KIPPING, Hutton, Essex, showed a selection of Alpine and hardy garden flowers, arranged in a setting of virgin cork, in imitation of a small rock-garden. There were Primroses, Hepaticas, Anemones, Saxifragas, &c.

Messrs. BARR & SONS, King Street, Covent Garden, London, W.C., also exhibited hardy plants and flowers, including many varieties of Narcissus which had flowered in frames.

Lady LEWIS, Harpton Court, Kington, Hereford, showed vases of Violets of the improved garden varieties.

Messrs. GEO. JACKMAN & SON, Woking Nursery, Surrey, had a remarkably fine batch of plants of Cyclamen ibericum amongst other spring-flowering subjects. We noticed a lilac-coloured form labelled C. i. lilacina. Sprays of Daphne Mezereum in the white and type-coloured forms were most freely flowered. There were also Irises, Primulas, Fritillaria aurea, Hepaticas, and many other plants.

Messrs. W. WARE, LTD., Feltham, Middlesex, displayed hardy flowering plants, many of which were Alpine species. The collection was arranged in a setting of cork with soil, &c., to present a realistic appearance. There were many Primulas in flower, including P. denticulata, Hellebores in variety, and Saxifragas, amongst which were well-flowered plants of Saxifraga apiculata, &c.

Lord HILLINGDON, Hillingdon Court, Uxbridge (gr. Mr. A. R. Allan), displayed 50 or more plants of Lachenalia Nelsonii, all of which were freely flowered and exhibited good culture. They made a meritorious group, and the effect was relieved by plants of Grevillea robusta intermingled amongst them. (Silver Banksian Medal.)

Messrs. J. CHEAL & SONS, Crawley, Sussex, showed a few hardy Alpine plants in flower in boxes. As a background were arranged small Conifers and other dwarf trees and shrubs suitable for the Alpine garden. Buxus balearica has relatively large foliage, the leaves being pleasingly edged with a narrow golden band.

The Misses HOPKINS, The Mere, Shepperton, showed Alpines and a selection of species of Primula, Hepatica, Saxifragas, &c.

Mr. J. WILKINSON, Highlands Gardens, Minchinhampton, showed Cyclamens of the papilio, speciosa, and fringed varieties.

Mr. F. H. CHAPMAN, Rye, showed Freezia virginalis and two pink seedlings, and also a quantity of F. Chapmanii.

Messrs. BROOKS & Co., Nurserymen, Worthing, showed a seedling of Primula sinensis labelled The Empress: the variety gave evidence of being a good break. An old garden plant now seldom seen in cultivation was noticed in Gardenia citriodora.

Mr. F. MOORE, Glasnevin Botanic Gardens, Dublin, exhibited flowers of a few new hybrid Lachenalias; these were remarkable for their large size and rich, golden-yellow colouring.

AWARD OF MERIT.

Helleborus "Peter Barr."—A variety with strong, erect growths and deep, richly-coloured purple flowers, with white stamens and anthers. The merit of the variety lies in its clear colour. Shown by Messrs. BARR & SONS, King Street, Covent Garden.

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshay, J. Forster Alcock, R. A. Rolfe, H. Little, W. Boxall, Sir Jeremiah Colman, Stuart Low, A. A. McBean, J. Cypher, F. J. Hanbury, F. M. Ogilvie, J. Charlesworth, W. Cobb, H. A. Tracy, W. H. White, Gurney Wilson, H. Ballantine, J. Wilson Potter, C. J. Lucas, Norman C. Cookson, R. Brooman-White, H. G. Alexander, H. J. Chapman, C. H. Curtis, A. Dye, W. Bolton, and F. J. Thorne.

Major G. L. HOLFORD, C.I.E., C.V.O., Westonbirt, Tetbury (gr. Mr. H. G. Alexander), staged an excellent group, perfect alike in the condition of the plants, their profuse display of flowers, and the admirable manner in which the whole was arranged, the various classes being excellently grouped for effect. The Society's Gold Medal was awarded for the group, and several novelties were given Awards. For new plants see Awards. Among the plants staged were many fine specimens, showing the effects of their good culture for some years past at Westonbirt. The Cattleyas comprised splendid specimens of C. Trianæ, the most remarkable of which were the varieties Hydra, Perfecta, Amabilis, Imperator Westonbirt variety, Optima, Katie Wigan, Bismarck, and Aurora. A plant of the beautiful, broad-petaled, white C. chocoensis, Westfield variety, represented it in fine condition. The Dendrobiums were freely flowered, and contained two new hybrids of good quality, viz., D. Perseus (nobile × Wiganiæ xanthochilum), and D. Psyche (Cassiope × Wiganiæ xanthodulum), the fine D. W. xanthochilum being also well shown, together with D. nobile nobilius, D. Ainsworthii amœnum, D. rubens grandiflorum, D. Apollo, D. Schneiderianum, D. Ophir, D. Rainbow, and others. From the back, the fine flowers of several good Lælia anceps Schroderiana, good Odontoglossum crispum, the fine O. Wilckeanum Rex, a grand O. Loochristiense with four spikes of 56 flowers (Cultural Commendation), and other elegant varieties arched forward above the Cypripediums and other dwarfer plants. The Cypripediums included C. Chapmanii superbum, the green and white C. Maudiæ, a specimen of C. Euryades with 20 blooms, C. Scipio magnificum, a very fine flower; varieties of C. aureum, including Hyeanum, virginale, Œdippe, and the pale yellow-green and white C. aureum Surprise; C. Lathamianum with about 20 flowers, and many others. The Lælio-Cattleyas were represented chiefly by pretty hybrids raised at Westonbirt, some being shown in quantity and exhibiting remarkable variation in the tint of their flowers, especially those of L.-C. Ariel (Gowanii × Dowiana aurea), of which about 70 plants were staged, divided primarily into two distinct colours, each set giving still more variation, their yellow, copper red, and ruby flowers being very distinct, showy, and abundantly produced. L.-C. Goldfinch (L.-C. Warnhamiensis × C. Dowiana aurea) was also shown in several forms, the bright yellow variety with magenta lip being the best; it is a very desirable hybrid. Others were L.-C. Arbaces (C. labiata × L.-C. Cassiope); L.-C. Aladdin (C. Warscewiczii × L.-C. Ingramii); L.-C. Pizarro (L. Jongheana × C. Dowiana aurea); L.-C. Dorothy (C. Schroderæ × L.-C. Doris); and L.-C. Barbarossa compacta, all distinct and pretty hybrids. Also specimens of the white Cœlogyne cristata, and variety lemoniana; a fine specimen of the scarlet Sophronitis grandiflora; the brightly-coloured Sophro-Lælia Psyche, a good example of Lycaste Balliæ var. Mary Gratrix; Brasso-Cattleya Digbyano-Mossiæ, B.-C. Thorntonii, B.-C. Madame Hye, and B.-C. Pluto were also included; a very striking effect was made with the massed forms of C. Trianæ in the centre, a group of the gold and red form of Lælio-Cattleya Ariel on one side, and of the copper-red form on the other.

Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. W. P. Bound), was awarded the Society's Gold Medal for an equally fine and well-arranged group, in which the handsome home-raised hybrid Dendrobiums for which Gatton Park is famous were the prominent feature, and these have never been shown in finer condition. The centre of the group had at the back a number of plants representing good forms of Cattleya Trianæ, Lælio-Cattleyas, Phalænopsis, &c. At one end were many graceful white and purple Calanthes, with the violet Odontoglossum Edwardii; at the other, Calanthes and the orange and scarlet hybrids of Epidendrum Boundii. In front, bright colour was given by the scarlet Epiphronitis Veitchii, Sophronitis grandiflora, and Masdevallias; and among the most prominent of the Dendrobiums were D. signatum, D. Wiganiæ xanthochilum, D. Wardianum album, Gatton Park variety, pure white with a yellow disc; and several new hybrids, two of which received Awards. Specially fine were Dendrobium Cybele aurora, and other forms of D. Cybele; a batch of pure white D. noblie album, D. Othello colossus, D. Mrs. Alfred Rogers (Hildebrandii × Findlayanum), a charming blush flower with a soft green disc. At one end were the handsome Cymbidium Lady Colman, C. Gattonense, and a selection of Phaius and Phaio-Calanthes; at the other, several finely flowered Cymbidium grandiflorum. With the showier kinds were a good number of curious and interesting species, including the dwarf Angræcum hyaloides, the gnat-like Pleurothallis macroblepharis, and other singular Pleurothallis; Bulbophyllum sauvissimum, Scaphosepalum antenniferum, Brassavola nodosa grandiflora, Dendrobium Hodgkinsoni, and other rare species.

Spathoglottis aureo-Veillardii, S. Colmanii, and other bright yellow and ruby-red hybrid Spathoglottis, raised at Gatton, the new white Diacro-Cattleya Colmanæ, illustrated in a recent issue of the *Gardeners' Chronicle*, the pretty Saccolabium bellinum, and other rare plants were also included, the whole forming a most remarkable group, and a fine exhibition of what can be produced by good cultivation.

NORMAN C. COOKSON, Esq., Oakwood, Wylam, was awarded a Silver-Gilt Flora Medal for a group of very fine Odontoglossums, in which were several home-raised seedlings, and a notable O. crispum Chapmaniæ (Cooksonianum × Cooksoniæ), flowering in two years from the first-made pseudo-bulb, which bore two flowers of fine shape heavily blotched with deep rose-purple, and which promises to be a very fine acquisition. Also in the group were O. crispum St. Alban, having a finely-branched spike of 28 flowers; the famous O. c. Puttinum, O. c. Mrs. Peeters, O. c. tessellatum, the handsome O. c. Mossiæ, closely blotched with purple; the beautiful O. c. Memoria Battle of Waterloo, illustrated in the *Gardeners' Chronicle*, January 11, p. 18, and other varieties.

Messrs. JAS. CYPHER & SONS, Cheltenham, secured a Silver Flora Medal for a varied group, in which were a good selection of fine varieties of Cattleya Trianæ, Cypripediums, Dendrobiums, &c., were included, the front centre being of scarlet Sophronitis in fine plants. Among the best noted were Dendrobium Farmeri with several spikes; the yellow D. Wiganiæ xanthochilum, fine forms of D. nobile, and some of its pretty hybrids; Odontoglossum Wiganianum, varieties of O. crispum, O. elegans Pollett's variety, O. Mulus, and a pleasing chestnut-red hybrid with primrose margin and tips to the flowers; Cypripedium Venus, and other showy Cypripediums; Brasso-Cattleya Thorntonii, Brassavola Digbyana, &c.

C. J. LUCAS, Esq., Warnham Court, Horsham (gr. Mr. Duncan), was voted a Silver Flora Medal for a group of varieties of Odontoglossum crispum, O. Adrianæ, and other Odontoglossums, together with a selection of hybrids of Cattleya Percivaliana, and a well-flowered example of Ansellia africana.

Messrs. CHARLESWORTH & Co., Bradford, secured a Silver Flora Medal for a group containing several quite new hybrids, two of which secured Awards. Another and still more interesting plant was Odontoglossum Eleanor (cirrhosum × Uro-Skinneri), the first hybrid of O. Uro-Skinneri. The ground colour of the sepals and petals is pale green, prettily spotted with chocolate red; lip white, with curiously-arranged dark red markings. The centre of the group contained the bright orange and red Lælio-Cattleya Hypatia, in company with a good specimen of the white and rose Eulophiella Elisabethæ, Cymbidium Woodhamsianum, a good selection of Cattleya Trianæ, and Odontoglossums, including the elegant O. Phœbe; the scarlet Odontioda Vuylstekeæ, the white Brasso-Cattleya Queen Alexandra, Angræcum citratum, and other rare species and hybrids.

H. S. GOODSON, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), staged an effective group of Dendrobiums, Odontoglossums, Oncidium splendidum, Sophro-Lælia Psyche, Lycastes, &c. (Silver Banksian Medal.)

Messrs. SANDER & SONS, St. Albans, staged a group in which the principal objects were two fine forms of their Cymbidium insigne Sanderi, both of which secured First-Class Certificates. Also specially noteworthy in the group were Odontioda Lairesseæ with a good spike of pretty purple and rose flowers; a good example of the white Cœlia Baueriana, Vanda suavis, Saccolabium calceolus, Epidendrum Wallisii, good Cattleya Trianæ, Cypripedium Curtisii (Sander's variety), certainly the best and finest in colour of its class; C. Orion var. aureum (insigne Sanderæ × concolor Sanderæ), with lemon-yellow flower spotted with purple, and Cattleya Trianæ triumphans, a large and beautiful form. (Silver Banksian Medal.)

Messrs. ARMSTRONG & BROWN, Tunbridge Wells, staged a group, principally hybrids, the central plant, Lælio-Cattleya Daffodil, being a charming novelty (see Awards). With it were a selection of brightly-coloured hybrids between Cattleya Trianæ and Lælia Cowanii, that varied considerably; a plant of the yellow Oncidium Jamesonii, several good Odontoglossums, cut flowers of Lælia Statheræ, Cypripedium Mary Beatrice, C. Helen II., and others. (Silver Banksian Medal.)

Messrs. HUGH LOW & Co., Enfield, staged a group in which was a plant of Odontoglossum crispum Carmen, a grand flower handsomely tinged and blotched with rose-purple, the margin and some small patches on the segments showing white. Others noted were the singular Pleurothallis Roezlii with five racemes of large purple flowers; a selection of Dendrobiums, including several of the white D. nobile virginale, Cymbidium Wiganianum, C. Ballianum, varieties of Cypripedium aureum, and C. insigne, C. insigne E. J. Seymour being a finely-formed and distinctly marked flower; a very dark form of Odontoglossum cordatum and Sophronitis Lowii, with yellow flowers, tinged with salmon colour. (Silver Banksian Medal.)

Mons. MERTENS, Mont St. Amand, Ghent, was awarded a Silver Banksian Medal for a group of good hybrid Odontoglossums, Cypripediums, Cattleya Trianæ, &c.

Mons. JULES HYE DE CROM, Ghent, Belgium, showed a small group of cut flowers of his very handsome white Cattleya Suzanne Hye de Crom (Mossiæ Wageneri × Gaskelliana alba).

Sir TREVOR LAWRENCE, Bart., Burford (gr. Mr. W. H. White), showed Zygopetalum Ballii magnificum, with fine white, wax-like flowers, the sepals and petals finely marked with deep rose and the base of the lip with claret colour. Also the neat little Maxillaria variabilis unipunctata.

Messrs. HEATH & SONS, Cheltenham, staged a selection of Cypripediums, Cattleyas, &c.

J. BRADSHAW, Esq., The Grange, Southgate (gr. Mr. G. G. Whitelegge), showed Cattleya Luddemanniana var. Empress, a fine white flower with a singular dark pencilling on the whole of the veining. Also Lycaste Skinneri Princess Ida, a distinct lightly-coloured form.

H. J. ELWES, Esq., Colesborne, Andoversford, sent varieties of Pleione Yunnanensis, and two hybrid Cypripediums.

FRANCIS WELLESLEY, Esq., Westfield, Woking (gr. Mr. Hopkins), showed Cattleya Parisiensis (C. aurea × C. Parthenia), a pretty hybrid with blush-white sepals and petals, the latter having a purplish veining; lip showily displayed, chrome yellow, lighter towards the crimped margin, and having a purple mottling in front.

C. L. N. INGRAM, Esq., Elsfield House, Godalming (gr. Mr. T. W. Bond), showed cut blooms of three fine forms of Lælio-Cattleya Dominiana Elstead variety.

Messrs. STANLEY & Co., Southgate, staged a group of Cattleyas, Dendrobium primulinum, D. crassinode, &c.

AWARDS.

FIRST-CLASS CERTIFICATE.

Cymbidium insigne Sanderi superbum, from Messrs. SANDER & SONS. A variety having large white flowers tinted with rose, the broad labellum being finely spotted with deep rose-purple.

Cymbidium insigne Sanderi splendens, from Messrs. SANDER & SONS. Flowers large and wax-like, white tinged with rose and having a distinct claret line on the sepals and petals and a mauve tint on the heavily-spotted lip.

Dendrobium Cybele, Gatton Park variety (nobile nobilius × Findleyanum), from Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate. One of the best and most perfectly-formed hybrids yet raised, the large and broad-petalled flowers having a white ground, the segments tipped with magenta-rose, the disc of the lip maroon with an orange blotch.

AWARD OF MERIT.

Dendrobium Chessingtonense, Gatton Park variety (aureum × Wiganiæ variety), from Sir JEREMIAH COLMAN, Bart. A fine yellow flower, with dark base to the lip.

Maxillaria luteo-alba, from WALTER COBB, Esq., Normanhurst, Rusper (gr. Mr. C. J. Salter). A fine old species, with white and yellow flowers, shown in grand condition.

Brasso-Cattleya Helene Maron, from Mons. CHAS. MARON, Brunoy, France. Probably a secondary hybrid of B.-C. Digbyano-Mendelii. Flowers large, pale lilac, with a few purple markings at the base of the fringed lip.

Lælio-Cattleya Pizzaro (L. Jongheana × C. Dowiana aurea), from Major, G. L. H HOLFORD, C.I.E., C.V.O. (gr. Mr. H. G. Alexander). A very distinct hybrid of fine substance, with well-displayed sepals and petals of bright rose colour. Lip a shade of orange, with some rose-purple markings.

Lælio-Cattleya Daffodil (L.-C. Mercia × L. Jongheana alba), from Messrs. ARMSTRONG & BROWN, Tunbridge Wells. A charming flower of medium size and fine substance, clear white, with a buttercup-yellow tint on the tips of the sepals and petals. Lip deep yellow, shading lighter towards the crimped margin.

Sophro-Lælia Felicia (L. pumila præstans × Sophro-Lælia Heatonense), from Messrs. CHARLESWORTH & Co., Heaton, Bradford. A bright purple flower with darker lip.

Odontoglossum Clytie (Edwardii × Pescatorei), from Messrs. CHARLESWORTH & Co. A very graceful hybrid, with branched spike of pretty rose-pink flowers barred with claret colour.

CULTURAL COMMENDATION.

To Mr. H. G. Alexander (Orchid grower to Major G. L. HOLFORD, C.I.E., C.V.O.), for a fine Odontoglossum loochristiense with four spikes bearing together 56 flowers.

To Mr. C. J. Salter (gr. to WALTER COBB, Esq.), Normanhurst, Rusper, for a fine specimen of Maxillaria luteo-alba, with about 70 blooms.

Fruit and Vegetable Committee.

Present: Mr. A. Dean (Chairman), and Messrs. A. R. Allan, E. Beckett, J. Davis, J. Harrison, J. Jacques, G. Kelf, W. J. Jeffries, R. Lye, J. Lyne, W. Pope, H. Markham, J. McIndoe, H. Parr, G. Reynolds, P. D. Tuckett, P. C. M. Veitch, O. Thomas, J. Vert, and G. Wythes. The absence of the Chairman and both Vice-chairmen was due to indisposition.

There was little brought to the notice of this Committee. Amongst the chief of the exhibits was a collection of 10 varieties of Apples sent by Lord ZOUCHE, Parham Park, Pulborough, the best fruits being those of Annie Elisabeth, Gloria Mundi, Blenheim Pippin, and The Queen.

Three varieties of Apples were displayed by T. B. T. HILDYARD, Esq., Flintham Hall, Newark (gr. Mr. Langstone). The varieties were Annie Elisabeth, the fruits much ribbed; Gascoyne's Scarlet Seedling, and a seedling named Langstone's Seedling, a variety much resembling Beauty of Kent.

Mr. W. PETERS, Leatherhead, sent fruits of two seedling Apples, also a dish of a late variety of stewing Pear much resembling Marie Louise D'Uccle for name.

SHROPSHIRE HORTICULTURAL.

FEBRUARY 28.—The annual meeting of the Shropshire Horticultural Society was held on the above date. The Mayor (Mr. R. S. Hughes) occupied the chair during the first part of the proceedings.

Mr. W. W. Naunton read the annual report, in which the committee stated that they had again to congratulate the members of the Society upon a most successful show, the attendance at which was in excess of any previous year. The total receipts from all sources amounted to £5,922 12s. 8d., being £283 17s. 5d. above that of the previous year. The number of annual subscribers had steadily increased, the subscriptions last year amounting to £536 11s. The receipts at the gates on the two days were also greater, amounting to the sum of £3,485 4s. 3d., as against £3,317 10s. 11d.

Mr. James Vine then presented the financial statement. With regard to the summer show, the prize money expended amounted to £1,238 12s. 3d. The Society's total receipts for 1907 amounted to £5,922 12s. 8d., and the payments to £5,136 1s. 8d., leaving a balance of £786 11s. The receipts from the summer show amounted to £5,683 9s. 4d., and the payments to £4,449 3s. 11d., leaving a profit on the summer show of £1,234 5s. 5d. Mr. Stainer was elected President for the ensuing year.

The committee was re-elected, Mr. R. D. Bromley filling the vacancy caused by the death of Mr. J. Evan Jones.

The honorary secretaries, Messrs. Adnitt and Naunton, were re-elected.

MARKETS.

COVENT GARDEN, March 4.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—Ed.]

Remarks.—The supplies of English Grapes are shorter and prices are firm. Best quality Denia and California Oranges continue to sell freely. Oregon Newtown Pippin Apples are much dearer; they are now arriving in a very fine condition. A good demand exists for Teneriffe Tomatos, but consignments of these fruits are small. A few boxes of Australian Apples received this week were at the time of writing awaiting a purchaser. *P. L., Covent Garden, March 4, 1908.*

The amount of trade this week is slightly in excess of that of last week, there being a rather better demand for the best samples of tubers. *E. J. Newborn, Covent Garden and St. Pancras, March 4, 1908.*

COVENT GARDEN FLOWER MARKET.

The market is crowded with imported cut flowers. Daffodils from the Channel and Scilly Islands arrive in large quantities, and considerably depreciate the value of those home grown. The amount of business done is much less than at the corresponding period of last year. Complaints are made that street hawkers sell flowers at lower prices than those at which the florists purchase them, but these cheap flowers do not bear a close inspection in regard to quality.

Pot Plants.

Good flowering plants have been selling more freely. Cinerarias are remarkably fine. The leading market growers have a special strain of these plants, in which are seen compactness of habit and large inflorescences of bright and distinctly-coloured flowers. Genistas are abundant and their prices are lower. Well-flowered plants of the old double white Primula are seen; the larger double-flowered varieties of this plant appear to have almost gone out of cultivation. The ordinary single varieties are fairly good. Begonia Gloire de Lorraine is now becoming scarce in the market. Spiræas are of better quality than those seen a week or two ago. Azaleas are over-abundant. It is surprising that the Belgian growers do not adopt the pyramidal form of training their Azaleas, for pyramid plants sell better and make higher prices than those with flat heads of bloom. Among Ericas, E. persoluta alba and E. Wilmoreana are the leading varieties seen. Boronia megastigma and Acacias in several sorts are obtainable. A. ovata and A. Drummondii are favoured by the florists. Ferns are supplied in large quantities from several growers; those in small pots have bright and fresh fronds. Palms are plentiful, but they are not selling readily. Other foliage plants include Aralias, Araucaria excelsa, Ficus elastica, and F. repens.

Bedding Plants, &c.

Several growers are now sending in "store" boxes of summer bedding plants such as Lobelias, Calceolarias, Zonal Pelargoniums, Marguerites, Fuchsias, and other subjects. The number of plants in each box varies from about 40 to 60. Hardy plants include Primroses, Polyanthuses, and Daisies in flower. Roots of garden plants are now abundant, also Carnations in pots. There are also Hyacinths, Narcissi, and other bulbs just starting into growth, and suitable for planting. Also Pansies and Violas with their first flowers opening.

Cut Flowers.

Daffodils are the leading feature amongst cut flowers. Those from English growers are certainly the finest. Emperor, Golden Spur, and Victoria are leading varieties. Some of the short-cupped Narcissus are abundant. Tulips are plentiful, the double-flowered varieties in several colours being very fine; the best have realised from 18s. to 30s. per dozen bunches. Forced Roses are now coming in; blooms of Richmond and Liberty have long flower stems and clean foliage. General Jacqueminot is also good; this cannot be had with long stems, but it is much more fragrant than the other red Roses named. Caroline Testout and Bridesmaid are the best pink varieties. A few good blooms of Mrs. J. Laing have been noticed. Callas and Eucharis are more abundant. Lily-of-the-Valley spikes from forced crowns are not of such good substance as those from the retarded stock. Orchid flowers are plentiful, and include Cattleyas, Cœlogynes, Cypripediums, Dendrobiums, Lælias, &c. Some very good medium-sized white Chrysanthemums are seen. *A. H., Covent Garden, March 4, 1908.*

CATALOGUES RECEIVED.

E. R. Davis & Sons, The Nurseries, Yeovil, Somerset—Begonias.
Thomas S. Ware (1902), Ltd., Ware's Nurseries, Feltham, Middlesex—Hardy Perennials.
Wm. Watson & Sons, Ltd., Clontarf Nurseries and 18F, Nassau Street, Dublin—Garden flowers.
William Thompson & Co., Ltd., Shipquay Street, Londonderry—Farm seeds, manures, and implements.
James Carter & Co., 237-8 & 97, High Holborn, London—Seeds.
Toogood & Sons, Southampton—Farm seeds.
J. Cheal & Sons, Lowfield Nurseries, Crawley—Dahlias.
Cooper, Taber & Co., Ltd., 90, 92, Southwark Street, London, S.E.—Wholesale list of Seeds.
Amos Perry, Enfield, Middlesex—Perennials; New and Rare Plants.
The Chemical Union, Ltd., Ipswich—Fertilisers.

DEBATING SOCIETIES.

WARGRAVE AND DISTRICT GARDENERS'.—At a recent meeting of this association Mr. W. H. Scott, of the Hermitage Gardens, Twyford, Berks., read a paper entitled "Do Plants Sleep?" He referred to the various movements noticed in certain plants at different times of the day, according to the varying state of the weather, temperature, and light.

PANGBOURNE & DISTRICT GARDENERS'.—A meeting of this association was held on Wednesday, February 19. Mr. F. Tunbridge, The Gardens, Three Elms, Henley-on-Thames, read a paper on "Annuals." The lecturer related what he considered to be the best methods of cultivating annuals in different positions and for various purposes. *E. W. D.*

BECKENHAM HORTICULTURAL.—At the meeting held on February 14, Mr. J. R. Pocock, College Nurseries, Bromley, gave a lecture on "Hardy and Rock Plants." The lecturer stated that care should be taken in selecting the stone for the rockery, as some kinds of stone soon became soft and crumbled. In building the structure a start should be made at the bottom, finishing with the largest stones at the top. Very choice plants should be planted near the base, where they can receive the greatest amount of attention. Plant firmly and incorporate plenty of grit, or sand, in the soil. Pieces of sandstone placed beneath the leaves help to prevent the foliage from damping in winter, and also keeps the roots moist in summer. *J. Carr.*

DEVON AND EXETER GARDENERS'.—A paper was read before the members of this society by Mr. C. Budd, Montpellier Gardens, Exeter, on "The Study of Plants in Ancient and Modern Times." Mr. Budd compared the methods of early times with those of the present day, and thus showed by comparison the great advance made in horticultural knowledge and practice. A paper was also read by Mr. Percy Meyer, landscape gardener to Messrs. Robert Veitch & Son, of Exeter, the subject being "Hardy Trees and Shrubs, and their Effective Arrangement." *A. H.*

JERSEY GARDENERS'.—The usual monthly meeting of the members of this Society was held on February 11. Mr. A. Smith, the President, occupied the chair. Mr. G. Cooper read an interesting paper entitled "Fruit Enemies and their Treatment," which was greatly appreciated. An interesting discussion followed. The annual supper, concert, and dance was held in the Oddfellows' Hall, St. Heliers, on February 18. About 100 members and friends were present. Afterwards a concert was given which was attended by an audience of about 150 persons. The silver and bronze medals won by the members in competition at the monthly meetings were handed to the winners by the President. *G. C.*

SALISBURY AND DISTRICT GARDENERS'.—At the last meeting of this society the proceedings were devoted to "Questions." Mr. Hibberd, of Wilton House Gardens, acted as leader, and some very important questions were forthcoming, resulting in an animated discussion. *W. Y.*

BRISTOL AND DISTRICT GARDENERS'.—A meeting of the above association was held on Thursday, February 27, under the presidency of Dr. Shingleton Smith. A large gathering of the members attended to hear a lecture upon "Orchids" given by Mr. Hunking, gardener to Alderman Dix, Hampton Lodge. The lecturer stated that the Orchid family was a very comprehensive one, and it would be impossible for him to speak of all the members. The successful flowering of Orchids largely depended upon the rest given the plants after their growth was completed. The floors of the Orchid houses at Hampton Lodge are formed of a layer of coke about two feet thick, and this is well saturated at times with liquid manure. The questions of ventilation, shading, insect pests, and diseases were dealt with by the lecturer. *H. W.*

GARDENING APPOINTMENTS.

(*Correspondents are requested to* ***write the names of persons and places as legibly as possible.*** *No charge is made for these announcements, but if a small contribution is sent, to be placed in our collecting Box for the Gardeners' Orphan Fund, it will be thankfully received, and an acknowledgment made in these columns.*)

Mr. JAMES CLARKSON, late Foreman in the gardens, Cally House, Gatehouse, as Gardener to Lady BORTHWICK, at Ravenstone Castle, Whithorn, Wigtownshire. (Thanks for contribution to R.G.O.F. box.)

Mr. FRANK GRAY, for over 4 years General Foreman, Shiplake Court Gardens, Henley-on-Thames, as Gardener to E. F. GILL, Esq., Lashbrook Lodge, Shiplake, Henley-on-Thames.

Mr. E. BLISSETT, for the last 3 years Foreman at Ivy Hall Gardens, Pocklington, as Gardener to Mrs. MILLS, Acomb Hall, near York.

Mr. R. BATT, for the past 3 years Inside Foreman in Lord NORTHBROOK'S Gardens at Stratton Park, Micheldever, Hants., as Gardener to Mr. BEAUMONT, Dodington Park, Chipping Sodbury, Gloucestershire.

SCHEDULES RECEIVED.

Brighton and Sussex Horticultural Society's Shows to be held in the Dome and Corn Exchange, Royal Pavilion, Brighton. Spring, April 7, 8; Summer, August 18, 19; Chrysanthemum, November 3, 4, 1908.

Breconshire Horticultural Society's Show, to be held in the Market Hall, Brecon, on Thursday, August 13, 1908.

Answers to Correspondents.

AMPELOPSIS.—*A. C. N.* The variety you have is probably one of the forms of the plant known in gardens as Ampelopsis Veitchii, the correct name of which is Vitis inconstans. This plant is extremely variable, and you appear to have obtained plants of an inferior variety. The variety known as V. inconstans Lowii should suit your purpose, as it assumes a bright red colour in autumn, the leaves being also of small size.

ASTILBE (SPIRÆA) JAPONICA FAILING: *Jeannet.* The clump which you label No. 1 has at some time received a check, which has resulted in killing the leading crowns, so that weaker axillary growths only have developed, and these are not strong enough to produce flowers. In No. 2 clump the principal crowns have developed properly, but this clump has not been subjected to the same degree of forcing as the one of which you complain.

CONSTRUCTING A SMALL ROCKERY: *G. S.* You will require 1 ton and a half of stone, either of sandstone or weathered limestone, and about five cartloads of light, sandy soil for constructing your rock-garden. Any spare soil you may have about the garden will serve to fill up the extreme centre. The width of the plot will not allow you to build higher than 4 feet above the ground level, but you could excavate the natural soil to somewhat diversify the site. The correct way to build a small rockery is to imitate a natural outcrop of rock. An inclined plane is generally more artistic than horizontal formations, and it enables the builder to project small bluffs of stone from the rock-bed and to recess the formation at will. On terraces of rocky pockets filled with soil plants will grow well, but there is nothing in such structures that calls for recommendation. A stone-supported bank with the lines of stratification well defined and a series of recessed plateaux of soil made thereon is the best scheme for such a garden. An excessive use of rock-stone is not desirable, and if you cover one-third of the rockery surface with stone, it will be sufficient. Try to get every stone of the rock-garden placed in such a way as to suggest they are outcrops of one rock mass that is partly covered by soil. It does not matter how much you vary the surfaces, or how widely dissevered are the prominent bluffs one from the other, provided you keep the natural formation of the rock-stones well maintained throughout. Allow the structure to settle well before you commence to plant.

GARDENER'S NOTICE: *Gardener.* Refer to the replies printed in the last issue. You might have given the man notice during his absence from duty.

GRAFTING APPLES AND PEARS: *Anxious.* Apples are generally grafted on seedling Apple stocks or on a dwarfing stock known as the "Paradise." Pears are grafted on seedling Pear stocks or on the Quince, the latter having a dwarfing effect upon the grafted Pear.

KENTIA: *Palm.* You do not say to which species the Palm belongs. Offer it for sale to some of the nurserymen, or make it the subject of an advertisement.

NAMES OF PLANTS: *W. G.* Dendrobium primulinum and Cœlogyne flaccida.—*W. H. R.* Dendrobium fimbriatum oculatum. *C. H. C.* Abies Pinsapo.—*S. N.* 1, Thuya plicata; 2, Thuya dolabrata; 3, Cupressus Lawsoniana; 4, Cryptomeria japonica var. elegans; 5, Cryptomeria japonica; 6, Bignonia species; we cannot determine which in the absence of flowers.—*J. H.* Cattleya Trianæ and Dendrobium nobile, both good varieties.—*F. T.* 1, Oncidium pubes; 2, Oncidium sphacelatum; 3, Odontoglossum blandum; 4, Masdevallia simula; 5, Stelis muscifera.—*J. J.* Cypripedium insigne. Recent importations have produced many varieties. The one you send is very similar to the original form. *W. E. S.* 1, Not found; 2, Odontoglossum gloriosum; 3, Odontoglossum Coradinei; 4, Oncidium Forbesii; 5, Masdevallia Veitchiana; 6, Cypripedium Calypso; 7, Cypripedium (Selenipedium) Dominianum.—*Correspondent.* 1, Picea excelsa; 2, Tsuga canadensis; 3, Cupressus nootkatensis aureo-variegata; 4, Cupressus pisifera plumosa aurea; 5, Picea ajanensis; 6, Rubus species, send again when in leaf.

PEACH BLISTER: *A. S.* This affection is generally brought about by cold north or east winds, although the disease itself is due to a fungus known as Exoascus deformans. The presence of the disease is largely determined by the situation of the trees; those in an exposed position being the most liable to attack. We are afraid that covering the trees with a material such as you suggest will prove of little avail; the better plan will be to follow the advice given by Mr. Fyfe on p. 100 of our issue for February 15. See also letters on this subject in our last issue, p. 140. Red spider may be combated in the summer months by a frequent use of the syringe or garden hose.

PEACH BUDS DROPPING: *F. L. B.* The injury is generallly caused through dryness of the roots at an earlier stage. During the resting season roots are often allowed to become too dry, and this, in the opinion of many competent growers, is the cause of the mischief. Excess of moisture at this season, or any other cause contributing to a check, will have the same effect.

PEACH SHOOTS DISEASED: *C. B.* The shoots are affected by a disease—Botrytis. Cut out the damaged shoots and burn them. Spray the healthy portions of the tree with a reduced solution of permanganate of potash. Prevent cold draughts and chills in the house.

PEACH SHOOTS: *C. H. G.* There is no trace of disease in the shoots received.

PELARGONIUM LEAVES SPOTTED: *G. M.* Leaves or portions of plants sent for examination should not be enclosed in a letter. They should be properly packed in damp moss and be enclosed in a box. Your specimens reached us in such a damaged condition that it was impossible to accurately determine the cause of the trouble. We do not think the spotting was caused by disease, but is rather the result of some cultural error.

PELARGONIUMS DYING: *P. G.* We cannot suggest a reason for the plants dying, unless we see one of the plants and know more of the conditions under which they have been cultivated. Trouble sometimes arises from sulphurous fumes escaping from the stokehole. If you are a Fellow of the Royal Horticultural Society, you can have an analysis of the soil and water conducted by Dr. Voelcker, 22, Tudor Street, London, E.C., on payment of a small fee.

PICEA: *C. H. G.* We cannot find any signs of organic disease.

SOIL INOCULATION: *W. F.* In our issue for December 7 last was published an article by Professor Bottomley, explaining the whole question of soil inoculation. Seeds such as you describe may be purchased, and some inoculated seeds were exhibited at the Royal Horticultural Society's meeting on Tuesday last.

STRAWBERRIES FAILING: *F. H.* We cannot tell the reason of the failure, except that it is due to some check during their season of forcing. Have the plants been too heavily dosed with applications of patent manures?

TULIPS FAILING TO FLOWER: *Tulips.* We find no disease present in the bulbs you send; the failure to flower is probably the result of the bulbs not being properly ripened before they were harvested last autumn.

VIOLET ROOTS: *F. E. G.* There is no disease present in the specimens received. The dead portions are covered with a saprophytic mould, which has developed on the dead tissue.

WALNUT TREE: *Mrs. J. B. D.* The Ivy is decidedly injurious to the Walnut trees, and you should therefore remove it without delay.

ORIGIN OF ERFURT EXPORT TRADE.

ONE of the greatest benefactors of the city and locality of Erfurt was Christian Reichart, who was born July 4, 1685, and died on July 30, 1775. The story of his life has been recently told by Dr. Hans Haupt in *Die Erfurter Kunst und Handelsgärtnerei*, and it cannot fail to appeal to all who are interested in horticulture. Educated for the law, Reichart employed his more than common mental faculties as Deputy Burgomaster, Councillor, Assessor to the Ministry, gymnasium (college) Inspector, and finally as Member of the Mercantile Commission. The highest services that he rendered to his country and to the town of Erfurt in particular were undoubtedly connected with the development there of gardening and farming. Knowing nothing of the cultivation of the land when the family property fell into his hands, he committed to writing everything that came under his notice concerning field and garden operations, so as to turn them to practical use, collecting a rich treasure of knowledge from observation and experiment that enabled him to bring farming and gardening to an unexampled degree of perfection. His work, *Land und Garten* (Treasury of the Farm and Garden), which appeared in 1753, and had in 1703 reached its fifth edition, is a masterpiece, which in many particulars forms an example that may well be copied today, and has been a guide to thousands of his countrymen. He appears to have included in its scope the entire range of field and garden culture, even that of medicinal plants. Of great excellence were the chapters on harvesting and the choice of seeds in regard to the retention of the useful properties and racial points in vegetables. In the year 1758 Reichart's *Einleitung in den Garten und Ackerbau* appeared, and many new methods concerning the cultivation of Cauliflower and other vegetables, the planting and cultivation of Watercress, the care of fruit trees, Grape vines, &c., were made known. The chapter on gardening as an art and science is a mine from which the most experienced of modern gardeners may extract something of value in his business. In Watercress culture he introduced the raised beds, with broad trenches between for conveying the water from the three springs. The water has a temperature of about 15° C., and never freezes in the winter, thus enabling growth to be made all the year round—a circumstance of the greatest importance to Watercress cultivation in Dreibrunnen. In the summer the water was spread over the raised beds by workmen with broad shovels or scoops. It is owing to this abundant application of water and to the accurately measured quantity of manure afforded that the heavy crops of Cress, &c., were obtained. The trenches, as will be understood, were carefully levelled and neatly banked. The area of the Dreibrunnen land is about 140 acres, the half of which consists of paths, banks or beds, and trenches; of the other half 57 acres are under vegetable crops, and 17 acres under Watercress culture. The Cress grown in the water channels is of peculiar tenderness and fine flavour, and in order to preserve these excellencies extraordinary care is taken. The laying-out of the land cost Reichart a large sum of money, and the people laughed at the first at what they considered to be his ridiculous labours, but when they saw the abundance of the crops obtained, they very soon copied his methods. Tettau, in his work, *Erfurt Past and Present*, states that the annual crop amounts to 50,000 schock of bundles (schock = 60 bundles or bunches).

During the occupation of Erfurt by the French from 1806 to 1815, the Cress greatly pleased these salad lovers, and the method of culture practised made so great an impression on Napoleon that he resolved on its introduction to France, and arranged to send to Versailles to have beds laid down according to the Erfurt methods, and from this place the system spread over the whole of France.

A similar method of raised beds and trenches was extended to the cultivation of Celery, Cauliflower, Kohlrabi, Cabbage Lettuce, Cabbage, Savoys, Cucumbers, Asparagus, Spinach, Leeks, Radishes, and potherbs. Regal wrote about this method of cultivation: "The beds are planted with Cauliflower and Kohlrabi at the margins, with Cabbage Lettuce and, later, Celery as the between crops. The Cauliflowers are succeeded by Kohlrabi, Cabbages, or Savoys." The gross income of an acre of ground in the Dreibrunnen land at that period came to the sum of £37, and the cost of cultivation, inclusive of rent, to £30, so that the net profit amounted to £7. The expense upon cultivation became much less when a larger area than an acre was undertaken, it being estimated that the clear profit from 1 acre in one year came to the sum of £24 in the year 1865.

Reichart's aims and teaching were, first and foremost, to get from all cultivated land the greatest possible clear profit. That this had not already been done was due, in his opinion, to the circumstance that those engaged in the business were practically, but not theoretically or scientifically, instructed. In a communication concerning this subject, he repeated the opinion of D. Kuhnhold: "We have here in Erfurt really no gardeners, seeing that they have not studied horticulture, but only a lot of agriculturists. A gardener should possess much more knowledge and experience than our folk here. It is a matter of common knowledge that when a groom falls from a horse, or a farmer from a village settles in our town, and works a year or two as a day labourer and rents an acre or two, he at once dubs himself a gardener, and allows himself to be publicly so called." These are the men who guard their secrets, instead of exchanging their opinions with other men, thus helping to elevate their entire class; and they were vexed when anyone, like Reichart, published his experiences in a book. It mattered to Reichart not in the smallest degree whether anyone belonged to the craft or not, but only what he performed. He could say, without boasting, that he by research and experiment had learnt more than a man who passed the whole time in his garden. It was a pleasure to him to publish for the common good that knowledge which he had acquired through his researches. As a means of teaching the results of experiments among farmers, gardeners, and the community in general, the higher schools were useful. Reichart busied himself heartily with the treatment of the subject of "Œconomy" in the high schools. The poor results of the academical lectures of that period were noticeable in the students themselves, because the whole subject of rural economy in those schools were mostly looked upon with disdain. The ground for such a scornful view of œconomy lay in the literature and, above all, in the method of instruction. The literature did not deal with the really important matters of the subject taught, and the teachers had no practical experience, but merely discoursed about things they had never seen. Reichart desired above all things that such teachers should speak about matters they understood, that the lectures should follow a systematic course, and that means should be found for practical work.

These desires of Reichart's have been long carried out in the high schools of Germany, and are worthy of mention, as showing how deeply he was fascinated by his problem and with the means for raising the industries of the field and garden. The means Reichart advised for reaching this end was the 18 years' course of cropping the land without fallow. This theory is particularly important, as having led to the fusion of farming and gardening. The inducement to

take this view was given by the heavy crops obtained from the Dreibrunnen land, and the excellence of the vegetables grown thereon, which had captured the markets of the country around Erfurt, so far as the means of road travelling at that time permitted. Besides this, the results of his cultures at Dreibrunnen caused a great increase in the area under seed crops, and started a flourishing trade in seeds with foreign countries. Already in Reichart's time the interior trade of Erfurt in horticultural wares had given way to export trade.

We give here the 18 years' course recommended by Reichart, which in the course of time led to the enormous extension of the seed trade of the town and neighbourhood. The only fault to be found with this system was the great number of labourers it required; but this righted itself in time, for the profits were so remunerative that the farmers and gardeners were able to pay higher wages than other employers, and, as a consequence, a shortage of workpeople was not felt. A worn-out piece of land was chosen for the course, and was heavily manured, and at the proper time dug deeply or ploughed with four horses, and the following course began :—

1st year—White Cabbage and Kales.
2nd year—Onions, or, if the care of this crop made too much work, Cabbage was planted, and usually did better in the second year than the first.
3rd year—Parsnips, red Beetroots, Radishes, Carrots, and eventually Cucumber seeds.
4th year—Safflower, Poppy, Beans. The only preparation of the land necessary is harrowing.
5th year—Red and White Carrots or Turnips and Parsnips.
6th year—Safflower, Poppy, and Millet.
7th year—Winter Rye.
8th year—Winter Rye. The second ploughing or digging and manure is given at the end of this year. This second crop is better than the first.
9th year—Barley and Summer Rye or Summer Wheat.
10th year—The land must this year be deeply dug or ploughed, and sown with red Carrots and white and red Beets.
11th year—Poppy, Anise, Safflower, Fœniculum vulgare (Fennel), Carraway (black), and Coriander.
12th year—Winter Rye.
13th year—Barley, Summer Rye, and Summer Wheat.
14th year—Millet, Fœniculum vulgare, Peas, Beans, Lentils, Coriander, &c.
15th year—Barley.
16th year—Carrots, Vetches, and Coriander.
17th year—Rye.
18th year—Oats.

Various alterations, according to Reichart, may be allowed, but the main principles of the course should remain. In this course of 18 years, while in 10 years garden crops exclusively are grown, the entire field cropping is made to serve gardening purposes. In this manner the vegetable field culture began, and later on came the flower fields, as the population took generally to the raising of flowers and flower seeds.

The above brief narrative touches on the chief results of the activities of a far-seeing, scientific cultivator, who was the founder of the trade of Erfurt as we know it to-day. *F. M.*

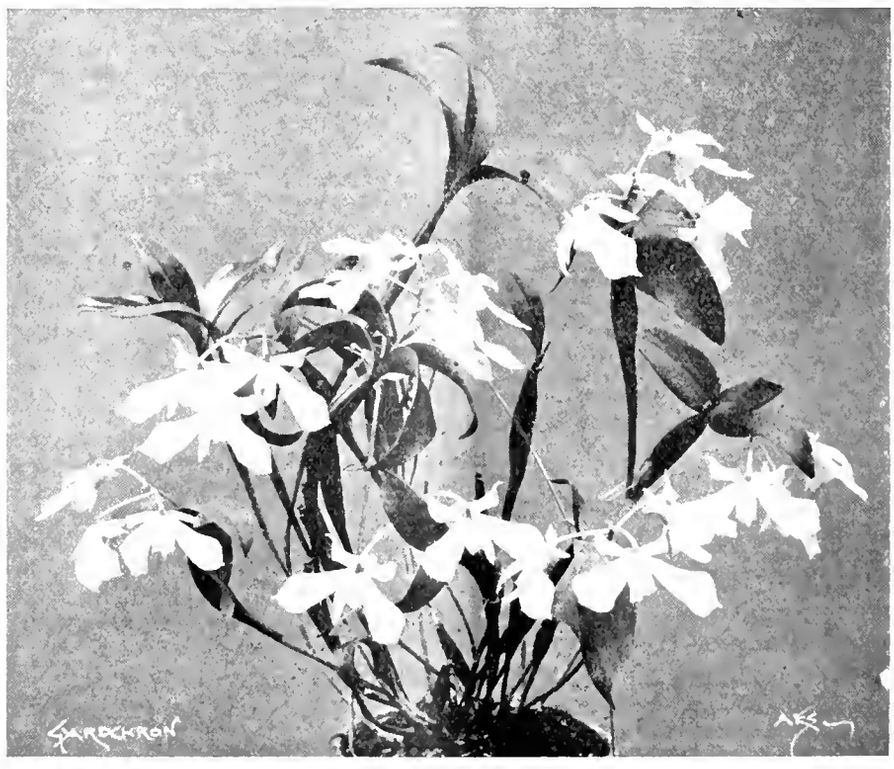
DENDROBIUM MADONNÆ.

OUR illustration (fig. 67), taken from a photograph by Mr. C. P. Raffill of a plant which recently flowered in the Royal Gardens, Kew, represents this pretty species, which unfortunately is still a rare plant in gardens. It belongs to the section which includes D. Johnsoniæ, D. atroviolaceum, and other species which are usually grown in gardens in the warm house in company with D. phalænopsis Schroderianum, D. superbiens, &c. D. Madonnæ is a tolerably free-growing and free-flowering species, the flowers being white with some rose-coloured markings on the front of the lip.

It was first introduced from New Guinea by Messrs. Sander & Sons, who flowered it in 1899.

FLOWERING BULBOUS PLANTS.

THE number of plants of a bulbous nature that may be planted in the spring is considerable, and with most of them smaller numbers are needed than of the varieties that flower earlier in the year.



[Photograph by C. P. Raffill.

FIG. 67.—DENDROBIUM MADONNÆ: FLOWERS WHITE, WITH ROSE-COLOURED MARKINGS.

An uncommon and charming bit of planting may be made by associating Hemerocallis (Day Lily) with one of the few plants of similar colouring, i.e., the Pilosum Poppy. This tawny apricot is little represented among our garden flowers. These Lilies flower over a long period, and more persistent still are the double forms, and among these last H. Kwanso fl. pl. should certainly find a place. Even a single group becomes finely effective, and though I prefer autumn planting, these Day Lilies are always to be found included among the plants of a bulbous nature recommended for spring planting.

The Anemone and the Ranunculus add a delightful brilliancy early in summer, when they are planted in the first week in March or earlier. Nothing quite fills their places, for both are refined and choice types of blossoms, so that in none of the picked and best positions are they incongruous and out of place. It should be remembered that the Ranunculus especially rejoices in plenty of moisture during its period of growth, and a watering occasionally with liquid manure is beneficial. One of the most gorgeous bits of planting I ever recall was a long, narrow bed, cut in a lawn, wholly planted with Ranunculi.

Last year I was struck with the effective use of Galtonia (Hyacinthus) candicans among the bedded-out plants. A large round bed had a bold central group of this summer flowering plant, while around it large flowered Petunias were established. The bulbous plants gave character and distinctness, besides variety of height, and well-defined lines. In some districts this Hyacinthus candicans is treated as a perfectly hardy subject, but I have found by experiment that in cold, wet soils the plants live longer and are more certain to flower well if lifted each year. In this, as with the Hemerocallis, not only the floral value has to be considered; not a little has to be allowed for the decorative value of the outline of the whole plant long before flowering commences. In this respect it is superior to the Gladiolus and the Montbretia, and I would never plant Gladioli and Hyacinthus candicans side by side.

Montbretias increase rapidly, and require to be lifted every other year if possible. To have them at their best, the corms should be planted singly and 6 inches apart. I planted them thus last spring in a moist position, and aspect due east, and some of the flowering stems grew over 4 feet in height, and produced a wealth of blossom. They had not been lifted for the winter, and were divided early in March after root growth had commenced.

The old-fashioned Spiderwort (Commelina cœlestis) has that subtle and almost indescribable appearance of being what is called "old-fashioned." In many gardens a satisfactory way of treating it is to grow it from seed and treat it as an annual. It is one of the few bulbous plants we can grow to flower the first season from seed sown in the spring. Besides the blue

variety there is also a white one, but this is not so desirable nor so decorative as the better known blue one. No one would dream of using this plant in the bedding-out scheme. It is distinctly a border plant.

I have not nearly exhausted the list of bulbous plants for spring planting. There are the Alstroemerias that should be established on some warm, well-drained border, as should also the hardier of the species of Amaryllis. I know of Crinums growing unlifted and unprotected in the cold clay soil of a London suburban garden. There are the Agapanthus Lilies to establish in tubs; the beautiful Tigridia pavonia, together with many newer hybrid forms, must not be forgotten, and no position is more favourable than a raised bed; the latter end of March is early enough to plant this last. The bulbs should not be deeper set than 3 to 3½ inches, nor farther apart than 4 or 5 inches. *Practical Gardener.*

AMERICAN NOTES.

WINTER IN THE PARKS.

Superintendents and gardeners in the Chicago and other North American city parks have a serious problem to consider in endeavouring to keep their plants alive during the winter. The keen winds that blow over Lake Michigan, when the temperature hovers around 10° or 15° below zero, cut off everything green that is exposed above ground, and the covering of 18 inches or so of leaves and straw litter gives the flower and Rose borders anything but an attractive appearance. The severe winters and hot dry summers are terribly hard even on the grass, and the appearance of the sward in April, all black and bare after an unfavourable winter, would dishearten anyone not used to it. But growth is very rapid when spring opens and the trees and shrubs take on lovely spring colouring here not seen in the British Isles. The Birches are especially beautiful with their warm, red-brown tints, overlaying the silvery white bark. The berries hang late on Berberis Thunbergii, one of the finest dwarf shrubs, perfectly hardy and beautiful at all seasons. But though the parks are dreary in winter from a horticultural point of view, they are not so otherwise. High toboggan slides are crowded all day, and well into the night, by merry throngs. The frozen lagoons are lively with skaters almost as enthusiastic over their sport as the neighbouring Canadians, while the warming and rest houses are full of happy, healthy and joking beings that would drive away melancholy from the most "grouchy" individual. An amount of good that is simply incalculable results from such grand park and boulevard systems as those of Chicago, whether one considers the health, happiness, or morals, of the dwellers in these immense and otherwise ugly cities. *H. R. R.*

ROSES.

Two new (?) Roses, named after prominent American ladies, are Mrs. Potter Palmer and Mrs. Marshall Field. It is a pity our growers did not wait until they had really good American kinds to name after American ladies, for the first is simply a colour sport from Mme. Abel Chatenay, and precisely similar in every other respect, while the other is a European variety, picked out from a number of others that reached this side without label or history. But these names have only been bestowed by market growers, and as real American Rosarians, such as Mr. E. G. Hill, of Richmond, Mr. John Cooke, of Baltimore, and others are working along legitimate lines, there are great hopes that this re-naming of old Roses—so long a feature—will cease.

CARDIFF CASTLE.

To the average reader the name of Cardiff will suggest coal and its attendant dust and smoke, but the city of Cardiff, in cleanliness and general smartness, is quite up-to-date and compares favourably with many of our leading cities. True, Cardiff is the largest coal-exporting port in the world, but the coalfield lies miles away.

Good gardens and gardeners abound in the district, as a visit to the annual summer and Chrysanthemum shows will prove; in connection with these one is reminded of the great loss both societies have recently sustained by the sudden passing away of the genial secretary, Mr. H. Gillett, who for many years has most successfully held that position. The public parks are not least among the horticultural attractions at all seasons. Our purpose, however, is to revisit the scenes of many triumphs of the late Mr. Andrew Pettigrew, who for many years served the late Marquis and Marchioness of Bute as head gardener.

Some of the late Mr. A. Pettigrew's triumphs were pot vines, Melons, and Cucumbers; of the latter a variety named "Cardiff Castle" is one of the best, and is still exclusively grown in the Castle gardens.

Mr. H. R. Farmer, who for several years loyally supported the late chief, and, as foreman, necessarily attended to the details of the operations resulting in such success, was in turn appointed to the important position of head gardener, and has had sole charge for about five years. The reputation of the gardens has been well maintained, and the pot vines in both the last seasons were fully equal to the magnificent specimens of years ago, whilst Melons, both in quantity and quality, were excellent. The varieties of Grapes used for pot culture are for the most part Black Hamburgh, Black Alicante, Grizzly Frontignan, Foster's Seedling, Black Morocco, and Alnwick Seedling. The two last-named are special favourites for the purpose, and both crop and colour exceedingly well. A pair of vines of Alnwick Seedling were arranged on an iron-framed arch (see fig. 68), and formed the chief item of decoration on the dinner table on the occasion of his Majesty the King's visit last season; these carried 20 bunches each of well-finished fruit, averaging 1 lb. in weight. Madresfield Court is also well grown, but Diamond Jubilee, after several years' trial, has been discarded. Mr. Farmer grows his vines in one season for fruiting the next, putting in the buds in January, and practises judicious feeding, "little and often" being his motto.

The ever-expanding city has so encroached upon the old garden, that its removal was imperative, hence houses and new gardens have been formed elsewhere. Those who have been privileged to visit the old garden will remember the remarkably fine fruit trees planted and so well trained by the late Mr. Pettigrew, mostly Apples and Pears, originally bush-formed, having long spur-laden branches in bearing condition from the ground to the extremity. These gigantic specimens Mr. Farmer is removing to other positions, and may he be successful with them.

Wending our way towards the new garden, we become reminiscent, and where once stood the home of our former host we find that his son, Mr. W. W. Pettigrew, has most appropriately arranged a pretty triangular flower-garden for the Corporation: and what a transformation is here! The magnificent, costly municipal buildings and Law Courts occupy the main position in the now open Cathays Park, and beyond, a grand pile of buildings is being erected, the University College, buildings fully worthy of the "metropolis" of Wales.

Visions of a distant past were vividly conjured up when inspecting the old Castle green, the moat, and the keep. The moat is now stocked with goldfish, and recently-planted Nymphæas, and will doubtless ere long be a pretty feature.

Fig. 68.—Pot vines as grown in Cardiff Castle gardens.

The new garden is a square of five acres, within substantially-built, brick-faced walls on three sides, the south being bounded by a green fence, otherwise open to a lovely stretch of lawn, skirted and broken by belts and beds of ornamental trees and shrubs, with a peep in the distance of the Castle tower.

The glass-houses are arranged in the background of the square; they are commodious, conveniently arranged as regards water and heating details; they are also substantially built (all teak wood), the work being done by the estate experts. The old span-roofed vinery has been re-erected in three divisions, and contains all Muscat-flavoured varieties. Madresfield Court has always been a favourite here, and still continues in favour, and so also does Canon Hall Muscat, but how rarely is the last-mentioned variety seen nowadays in good condition.

The wall carries a 90 feet by 14 feet Peach house in three divisions, with trees on a curved

trellis and on the back wall, the arrangement admitting of plenty of light for all the trees. There are several span-roofed houses 60 feet by 20 feet, besides the large vinery is 60 feet by 26 feet. Behind the Peach range wall are a number of useful open and closed sheds, offices, messrooms, &c., and underneath these, in addition to the boiler-house, there is capacious cellarage, 180 feet by 14 feet, which is intended for wine storage, Mr. Farmer having charge of the famous "Castell Coch," and other vineyards on the estate. Castell Coch vineyard is about 9 acres, and has, I believe, been in cultivation from the late 'seventies. It is impossible here to enumerate all the good plants contained in the houses—Palms, highly-coloured Crotons, and general decorative species, "Malmaison" Carnations in large quantities, excellent quality, and size; 300 Calanthes, Eucharis grandiflora and other species, large specimens of Adiantum tenerum Farleyense, &c. Nearly every gardener nowadays has a "pet" Tomato of his own raising, very often better than the best. Cardiff, not to be outdone, also has one, and without wasting too many superlatives upon its description, it really is a good one both in cropping qualities and in flavour.)

Renovations in the pleasure grounds are being made, and quite a large programme of work is in prospect. Probably a watercourse, called the "Feeder," which runs through one part, may be utilised for ornamental effect. It will be interesting to watch developments in this 40 acres of pleasure-grounds, where success has certainly been achieved during the past season in colour effects. Large beds, sufficiently widely separated by greensward, are admirably adapted for bold treatment. One of these beds was gorgeous with three colours of East Lothian Stocks behind a front border of the white variety.

Speaking of colour effects, why are our gardens not arranged with a view to these matters as regards their permanent subjects? Trees and shrubs in almost endless variety are at hand for the purpose, and what magnificent and various pictures are possible with an artist's mind and eye to conceive and arrange the first making, or indeed the renovating, of old gardens! *Monganwg.*

THE ROSARY.

CULTURAL NOTES FOR MARCH.

As it is well to safeguard the plants against all danger from severe weather, the protective material already about them should not be entirely removed until the end of the present month, when all danger from this cause will probably be passed. Standard Briar stocks that have been injured by frost can now be shortened back to sound wood. As the top growths of most Roses become exhausted after the bushes have been planted for a few years they should be cut away and their place be taken by younger wood. The pruning of hybrid, perpetual, and other varieties of Roses can in the south be proceeded with at intervals of a week or 10 days, and be continued throughout the month. The Tea-scented, Noisette and other tender varieties should be pruned from the end of March until April 10. In the north and Midlands the operation should be done from 10 to 20 days later, but the cultivator must be guided by the season, aspect and local circumstances. Old rosarians used to prune their Rose trees in the autumn, but their varieties were limited, and the plants were of a more hardy constitution than many of our present varieties.

Notwithstanding the recent severe weather, Roses are exceptionally forward, and strong-growing varieties of the hybrid perpetual type can now be pruned. The shoots should be cut back to from five to eight buds, weaker growing plants to four or six, but the severity of pruning should depend on the health of the individual.

Plants of the Moss, Provence, Hybrid China, and summer blooming varieties should have their superfluous shoots and old wood removed (if these were not cut off directly after flowering), leaving only the best ripened growths of the current year. Austrian and Penzance Briars should be similarly treated. Any Roses that have been injured by the late frosts should be cut back to sound wood by the end of March. The pruning of Teas and Noisettes can be left until the end of the present month or early in April.

Roses that are planted out under glass will now be breaking into growth freely, and as the house has been closed for a few weeks a little ventilation can be given in the middle of the day by the top ventilators. An occasional syringing with clear water will keep down insect pests, including red spider. An atmospheric temperature of 50°, rising to 55° with the sun's heat, should be maintained, and an increase of ventilation and atmospheric moisture must be permitted as the season advances.

The repotting into 5-inch pots of the grafted plants should now be well advanced. Vaporise at intervals to destroy insect pests, and place the plants well up to the light to prevent a weakly growth. All the earliest forced plants that have flowered can be removed to a cooler house to make room for the final batch of the autumn-potted plants that are now in a cold house or frame. These plants will continue the season of flowering until the end of May or early June, after which the outside plants will be giving a supply of flowers.

As the blooms are cut from the early house, the old flower shoots that are well matured can be used until the end of the month for herbaceous grafting, if stocks are available for the purpose.

ROSE CUTTINGS.

Any surplus wood can be used as cuttings in the propagation of Roses on their own roots. Rose cuttings are often rooted on a bed over a hot water tank, a practice to be recommended, but as a rule the old-fashioned hot-bed made up outside is resorted to. A two-light, box frame measuring about 11 feet 6 inches by 7 feet 6 inches is the handiest for the purpose. In order that the bed may retain its heat for a considerable time, it should be from 3 to 4 feet thick at the back and not less than 3 feet 6 inches deep in the front, after first being well trodden and allowed to settle. The hot-bed should be made of well-fermented manure that is not too moist, and a clear margin of 18 inches should be allowed all around the frame so that a fresh lining can be supplied when the heat declines. As soon as the bed is completed, the movable boxes with the lights can be placed on the top of the hot-bed, and when the bottom heat has dropped to 75° or 80° the pots containing cuttings should be plunged in a layer of cocoanut fibre or fine ashes. If there is an excess of vapour in the frame, provide a little ventilation at the back, but without unduly lowering the temperature. Place one, or not more than two, cuttings in each small pot; by the use of pots the ball of soil about the roots can be kept intact when the rooted plants are repotted. Well-ripened portions of shoots having not more than two nodes or joints usually root freely. The best rooting medium is a sandy loam with a layer of pure sand on the surface. The heat can be properly maintained until the cuttings are well rooted, by linings of manure, and it may be conserved at night time by placing mats or other coverings over the lights. Shade the cuttings from bright sunlight during the daytime. They should be well rooted in a fortnight or three weeks, and when they are well established they should be shifted into slightly larger pots. *J. D. G.*

WILD ROSES.

HERR F. BRETTSCHNEIDER gives utterance, in *Gartenflora*, to regrets that Wild Roses are not made more use of in the public gardens and parks of Germany. His complaint will perhaps find an echo in the minds of many who have marvelled at the absence of this beautiful native flowering bush from such places in this country. Our Wild Roses, grouped into three or four well-marked species, exhibit a wonderfully great range of variety, and many of them are incomparably more beautiful than the specimen shrubs so often grown in public gardens. But of course they take up a considerable space if they are to be allowed to show themselves at their best, and to many people plants that are native are also worthless. Perhaps some direction of public taste might be given by the more frequent use of such splendid Roses as Anne of Geierstein or Jeanie Deans, which, like many others of their class, are free-flowering, of good habit, and are also beautiful in form and foliage in the season when they are not in bloom.

VEGETABLES.

AN EARLY SPINACH.

THE older and smaller-leaved varieties of Spinach are usually sown for an early supply of this vegetable, but a new introduction—The Carter—comes in much earlier and has a larger leaf than these older kinds, and these are important details at this season. The new variety has thick, fleshy, dark-green leaves, and does not run to seed so quickly as the prickly or smaller varieties. On account of its larger size, the plants should be afforded more space than is given to the older type. For several years I relied upon the Victoria variety for my first crop of Spinach, but The Carter is much superior to Victoria, and its extra earliness is a great gain. Spinach sown on a warm border germinates and grows quickly, and on good land it is fit for use in a few weeks after sowing. Many gardeners sow the seed too thickly. When grown closely together it is impossible to obtain good leaves, and a thick sowing has the effect of causing the plants to bolt. A severe thinning of the seedlings well repays for the trouble. In many gardens the culture of winter Spinach is impossible, and in such cases an early spring supply is especially valuable. For this sowing The Carter is to be recommended; it matures quickly and the leaves when cooked are of excellent flavour and of a deep green colour.

TWO EARLY POTATOS.

AMONGST the many varieties of Potatos in cultivation it is not an easy matter to select the two best, but for an early supply of tubers the varieties May Queen and Ninetyfold are probably unsurpassed. Many persons have room in their gardens for an early crop of this vegetable, although they may be unable to grow later ones on account of the land being required for winter vegetables. The varieties named are especially valuable in this case, as they mature so quickly, thus leaving the ground available for other crops.

To take May Queen first—this is a free cropper, and its name is most appropriate, for given a good soil and a warm border, it is ready for harvesting in May; indeed, one of the chief characteristics of this variety is that as soon as the tubers are large enough to lift they are of excellent quality. The haulm is very dwarf, and this character makes it a suitable border variety for planting at this season when warm sites are none too plentiful in the garden. It differs from the older early Ashleaf variety in that most of the tubers are of a size large enough for use, thus giving a much greater crop. In the southern parts of the kingdom, May Queen is a favourite for early market supply. Of late years this

variety has been largely grown in Cornwall, and I strongly advise its planting in gardens. The haulm is of a hardier nature than that of the Ashleaf variety, and it is not so readily injured by frost.

Ninetyfold is a distinct Potato to May Queen, but it is its equal in point of quality. It produces a splendid crop of large tubers and, in my opinion, is second to none as a cropper when its season is taken into consideration. This variety has been in commerce for some years, and long enough to prove its merits. It was raised about ten years ago, and has found increased favour yearly as it has become better known. Even when lifted late in May or early in June the tubers are of remarkable size and in great quantity. Ninetyfold is a more robust grower than May Queen, therefore I recommend its culture to northern growers or for heavy land. The haulm is very strong, though dwarf, and I advise the planting of moderately large seed tubers, and the allowing of plenty of room between the rows, for there is no gain in crowding the plants. The tubers when cooked are of excellent quality, and of remarkably dry texture for an early Potato. For many years the Ashleaf varieties only were grown for first supplies, but since their introduction May Queen and Ninetyfold have largely supplanted them, for these newer kinds are not so readily injured by spring frosts, and they give earlier and heavier crops. *G. Wythes.*

THE FERNERY.

HARDY FERNS.

As the season has now returned when Fern collections can best be overhauled in preparation for the period of active growth, a few words in that connection may not be out of place. After the long rest which the plants have had since they became dormant in the late autumn, they are now in the best condition to stand removal or even the drastic operation of division for propagating or other purposes. The chief other purpose we have in view is the separation of bunched-up and crowded crowns which result from the growth of lateral offsets, which all the crown-forming Ferns—the Lastreas, Shield Ferns, and Lady Ferns—produce more or less abundantly. If these are permitted to accumulate, the inevitable result is that the main or mother crown suffers by competition with her offspring, the fronds become smaller, and, in the case of varieties, develop less character, while the offsets themselves are naturally also checked by root competition below the soil. Another evil is that, owing to the crowding together of the fronds, scarcely any of them can grow freely, and the result is a tangled bush instead of a symmetrical and handsome plant such as an isolated single crown can produce. At the present time, as the new fronds are still snugly packed away in the crown, while the old fronds, even of evergreens, have become shabby and in any case will perish early in the season when the new ones monopolise the vigour of the plant, division can be effected with little risk of damage, all that is necessary being to avoid squeezing the crowns. The whole plant may be forked up bodily, if necessary, to facilitate separation, and it will then be seen that each secondary crown is attached so slightly that it can be forced off with a blunt trowel, and will then come away with its own independent bunch of roots, all ready for separate planting, while the main crown remains practically intact to same end. In the case of the Lady Fern, lateral crowns occur less definitely, the central crown often splitting into two or more instead, each gradually growing away from the other, leaving a sort of Siamese twin connection. Here separation is not so easy, but can be effected if the upper parts of the connecting link be cut partly through and the two or more crowns forced gently asunder by hand pressure, when each will be found supplied with roots as with the other Ferns cited. In any case, the results of these dividing operations is a much robuster individual growth, a greater development of the varietal character shown by the fronds, and a better display of same by the freedom of all-round growth permitted. Some Ferns, such as the various Polypodies, Bladder Ferns, and Spleenworts, which do not form definite crowns, but have a more or less bunchy or diffused character, due to creeping rootstocks, and the formation of separated fronds are best left alone, as they do not suffer in the same way; but if it is desired to increase the number of specimens, the Polypodies may be divided by cutting off portions of these creeping rootstocks provided with a frond or two and a growing top, each such portion then rooting and establishing itself independently. The Spleenworts and Bladder Ferns, if in good clumps, can be pulled apart and separately planted, but otherwise should not be meddled with. Hartstongues and Blechnums stand somewhat midway between the two kinds of rooters, but if grown to clump form, individual centres of growth can be easily seen, and can be pulled asunder in like fashion. It is, however, not advisable to disturb either of these unless for propagative purposes, as the same reason does not exist as with crown-forming Ferns proper. Ferns in pots should be left alone if in good condition, unless re-potting is required, owing to need for further root room. In this case, pots a size larger should be chosen; the old ball, if not sour or full of dead roots, should be left intact, and good soil carefully filled in to the space available. The best general compost for Ferns is one part good loam and one part leafmould, with a liberal dash of coarse silver sand, but in the open ordinary good garden soil, not clayey, permits of very healthy growth, the main desiderata out-of-doors being shelter from wind and, if possible, some shade from hot sunshine. Beds or rockeries facing north are best as affording these conditions. Finally, we advise our readers not to devote space to the common weed forms of British Ferns as hawked about the streets or sold for a penny a root by nurserymen, but to obtain a selection of good varieties, many of which are cheap enough to be within the reach of all. *Chas. T. Druery.*

FIG. 69.—MAXILLARIA LUTEO-ALBA WITH 70 FLOWERS, AS SHOWN BY WALTER COBB, ESQ. (GR. MR. C. J. SALTER), AT THE LAST MEETING OF THE ROYAL HORTICULTURAL SOCIETY.

(See *ante*, p. 158.)

The Week's Work.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

The Orchard house.—Trees of Apples, Pears, and Plums in pots that are intended to furnish a supply of ripe fruit a little in advance of the ordinary outdoor crops should now be placed in a cool house. If the trees received the necessary attention last autumn in the matters of repotting and top-dressing, and have been properly plunged during the winter, their roots should be in a satisfactory condition for gentle forcing. They should be placed in a light, airy glasshouse, and ample space must be allowed about each tree. Fumigate the plants before the blossoms expand, and whilst the flowers are open admit plenty of ventilation in agreement with external conditions, both by night and by day. During wet, dull weather, a little artificial warmth will be beneficial. The blossoms of Apples and Pears should be pollinated daily. As soon as the flowers fade, syringe the trees on fine days in the morning and again in the evening. At the proper time attend to any necessary disbudding, stopping of the shoots, and thinning of the fruits.

Cucumbers.—Early raised Cucumbers planted as advised in a former Calendar upon hillocks of a suitable compost will, with the increased light, make a rapid progress in growth. A high temperature, accompanied by an abundance of atmospheric moisture, must be maintained in the pit: the night warmth should be 70°, and the day (with sun's heat) 90°, but ventilation should be carefully admitted when the temperature reaches 80°. Replenish the hillocks as the roots demand it with light top-dressings of fibrous loam, mixed with a small quantity of flaky leafsoil and horse manure, and enriched with some fine bone meal, or some other suitable fertiliser. These top-dressings, combined with applications of tepid, weak liquid manure, will maintain the plants in a vigorous state of bearing. Attention must be given to the proper tieing, thinning, and stopping of the shoots, and in order that the plants may not become crowded, each lateral should be stopped at one leaf beyond the fruit. Remove old and useless leaves, and do not overcrop the plants.

Cucumbers in frames.—The present is a seasonable time for preparing ordinary frames for summer crops of Cucumbers. Prepare the necessary fermenting material by mixing stable manure and tree leaves, turning the heap a few times for the purpose of dispelling the vapours that are formed during fermentation. The bed should be about 5 feet in depth, and be 18 inches wider all around than the limit of the frame. Place a single layer of thin turves over the bed inside the frame, and on a hillock of suitable compost under the centre of each light, plant the Cucumbers when the temperature of the bed has declined to 80°.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Cucumbers.—Plants which were planted early in January in the Cucumber houses should now be bearing freely. Do not overcrop them in their early stages, but attend regularly to the thinning and stopping of the growths, encouraging the plants to replenish the whole of the trellis with young shoots. Never allow any fruits to remain on the plants after they are ready for use, as they will keep perfectly fresh if cut, and their stalks placed in salt water, storing them in a structure where the atmospheric temperature is similar to that in the house where the plants are cultivated. Apply a little top-dressing over the roots about once a fortnight. Never allow the plants to suffer for want of moisture at the roots or the fruits are certain to be bitter. Apply plenty of stimulants to the roots when the plants are in full bearing, for the purpose of which drainings from the farmyard, properly diluted, will be found excellent; by way of change, apply Clay's fertiliser according to the directions. Damp the paths during the afternoon with strong manure water. Strong plants may now be put out in frames on well prepared hot-beds. These will require careful nursing till the weather is more genial. The soil should be warmed and the plants put out during the warmest part of the day. Do not use an excessive degree of bottom heat, but endeavour to maintain an even temperature by adding fresh linings of fermenting material as required. A little ventilation is necessary early in the morning to allow any condensed moisture to escape before the sun has power to burn the foliage, but the lights may be closed early in the afternoon, conserving as much sun heat as possible. The lights should be well covered at night with mats or similar material. Make another sowing in small pots for a successive crop.

Tomatos.—Early autumn-sown plants will now be bearing freely, and little difficulty will be found in maintaining a good supply of ripe fruits from the present time onwards. The plants may now be cropped much more freely, but liberal feeding will be necessary. Successional plants, which have been placed in their trial pots should not be unduly forced, but encouraged to make stout, short-jointed growth. Admit air freely whenever the weather is favourable. A good sowing of seed should now be made for raising plants to furnish the principal supply during summer and autumn, both for growing under glass and planting in the open. For the latter purpose care should be taken to select those sorts only which are free-fruiting, and which mature quickly. Many of the decorative kinds of Tomatos are not only extremely ornamental, but are also useful, the flavour of many of them when well ripened being superior to many of the larger-fruited kinds, and where the fruits are eaten in an uncooked state, I strongly advise some of these should be grown. Sunbeam, a yellow-skinned variety, is one of the best, and is well suited to anyone who has only a limited amount of glass.

Cauliflowers.—In many districts it will now be perfectly safe to put out autumn-sown plants in their permanent quarters, but a sheltered site should be chosen, and if it becomes necessary, owing to exceptionally severe weather, some slight protection should be afforded the plants. A few small Spruce boughs placed round each plants is as good as anything. Plants growing in pots which are intended to yield the earliest supplies ought now to be well established, and these will be much benefited if a good surface dressing of decayed manure and loam be given them, and manure water every other watering. Grow them in a cool house near the glass. Make another good sowing of seeds of the varieties Autumn Giant and Early Giant.

PUBLIC PARKS AND GARDENS.

By JAMES WHITTON, Superintendent of the Parks and Open Spaces in the City of Glasgow.

Provision of full-sized parks.—In an earlier article I alluded to the difficulties attendant on the acquisition of sites generally. When in municipal politics the question of the hour happens to be that of parks extension, the number of eligible situations recommended generally by interested parties—is often considerable. When however, they come to be examined it is difficult to find one suitable to meet the many requirements which parks are expected to serve. The area must be sufficient to admit of due provision for the playing of the popular outdoor games, such as cricket, football, and hockey, all of which demand more space than the games of tennis, croquet, or bowling. Then, as boating and model yacht sailing are yearly increasing in popularity, provision has to be made for one or more sheets of water for these pastimes. These sheets of water can serve a two-fold purpose by providing a winter amusement such as sliding and skating when frosts prevail. Besides these, free space must be provided for children amusing themselves in safety without restriction; while the tastes and wants of the elderly people and invalids must likewise be considered. Along with these, the convenience and accessibility are factors of no mean importance; while the price of the land and the cost of laying it out to meet the requirements indicated equally demand the most careful consideration.

The question of local feeling.—In the selection of a site for a park, local feeling usually has less influence than in the case of the smaller areas already dealt with. This is chiefly due to the fact that the choice of larger areas is more limited, and, as the initial outlay is greater, the authorities are not so readily disposed to yield to the clamour of persons who, not knowing all the facts of the case, are unfitted to give an opinion on its merits. Most frequently the greatest difficulty is that of price. Naturally, the majority of landowners insist on getting the highest possible value for their property, and when the situation happens to be in a district where building sites are in demand, the question of price is a matter of serious moment to urban authorities, whose rating power for park purposes may be too limited to meet a great expenditure.

Suitability of disused residences.—In the neighbourhood of an expanding city a situation possessing all the requirements is rarely available. There is one, however, not infrequently encountered, which goes a long way towards the desired object, and is readily accepted and appreciated by the town dwellers. That is an old residential estate well furnished with fully-grown trees and shrubs. If such be exposed for sale in "eligible building lots," which means the ultimate cutting down of the grand old timber, the chances are that the feeling of resentment created in the minds of the townsfolk by such a proposal will be quite sufficient to raise the question of its acquisition as a park. In this connection many persons will assert that the purchase of such a place is brought about purely on sentimental grounds, consequently a higher price, they say, is demanded and is paid for it, when a cheaper piece of land, perhaps contiguous, or in the vicinity, but devoid of trees and the ordinary adjuncts of a residential property, would have equally well served the purpose. With this view I entirely disagree, as being too narrow and parochial for the situation. We all are more or less creatures of sentiment. Therefore, when public sentiment tends towards the preservation of the historical or picturesque environment of a city, it is an evidence of a proper appreciation of its amenities. Quite apart from the point of sentiment, should it happen that such a site is placed as the alternative to one with no natural adornment, though the price may be from a fourth to a half more, I would, from experience of both types, and from a public point of view, recommend its purchase as the better investment. In the first place, considerable value should be put on the appreciation of these old places by the public, who find in them a sense of rest and retirement which, after the noise and bustle of busy streets, is most enjoyable; while in the many natural features characteristic of old country houses there is a perpetual source of charm and pleasure which cannot be found in newly-made places, no matter how skilfully planned or planted they may be. Then it also possesses the further advantage of being made quickly available for public use, requiring, in most cases, only the widening of the footpaths. The public have thus the immediate use of their property, while the authorities have time to study the position before making those alterations which probably will be necessary to make the place suitable for its purpose. In adapting such a situation for public use I have found that the costs are infinitesimal in comparison with the formation of a new park on what was purely agricultural land—a point which, in the end, will prove the value of the investment.

Work of adaptation.—In adapting a property of this description for a public park, every endeavour should be made to retain its particular characteristics. Some parts may require drastic alteration, but every feature ought to be most carefully studied before making any serious change. The disposal of the mansion is, perhaps, the most difficult problem. Some designs lend themselves readily for adaptation, and no serious expense will be involved in converting such a house into a local museum, reading-room, restaurant, or similar institution, such as may be required to meet the wants of the public or the department; while the stables and usual outbuildings can be utilised for park work generally, as well as providing shelters and waiting-room accommodation. Another feature which ought to be retained is the garden. This particular adjunct of a residential property always proves one of much interest to the public. Though the cultivation of vegetables has to be discontinued, if the quarters are used as a nursery for trees and shrubs, as well as a reserve for the flower garden proper, the educative value which a park ought to possess will be very materially increased.

PLANTS UNDER GLASS.

By Thomas Lunt, Gardener to A. Stirling, Esq. Keir, Perthshire, N.B.

Seedlings.—Plants raised from seeds sown last month must not be kept in a close atmosphere, and as soon as they are fit to handle they should be pricked out singly and be afterwards placed in a position close to the glass. Cold draughts must not be permitted to reach them, and they need shading from bright sunshine. Watering must be carefully done at this stage.

Primula stellata.—Plants of the "star" Primula, potted into 8-inch pots and grown for a second year, form splendid specimens when in flower for decorative purposes. These old plants are late in coming into bloom, which is an advantage, for they prolong the season after the one-year-old plants have passed out of flower. Some time before they are repotted a portion of the bottom leaves and all the flower stalks should be cut off, and a mixture of leaf-soil and sand be pressed firmly around the collar of the plant, when in a short time fresh roots will protrude from the neck of the plant; during repotting care must be taken not to damage these fine roots. After potting them place the plants in a house having an intermediate temperature, and shade them from bright sunshine. Apply water sparingly for some time after potting. Other varieties that are desired for another year may be propagated by layering. The shoots should be prepared as in the case of Carnations by making a slight incision half through the stem and then pressing the shoot firmly into leaf-mould and sand piled well above the rim of the pot. A suitable position for the plants at this stage is a shelf in the full exposure to the sun in a vinery. Primula shoots may be rooted freely in this manner, but it is essential that the compost should always be slightly damp, although not wet. In about six weeks these layers will be ready for separating from the parents, when they must be potted into small pots and be given a similar treatment to that afforded to seedling Primulas.

Caladiums.—Plants that are starting into growth should have the old soil shaken from their roots and be repotted singly into small pots. Very little water will be required until the plants commence to grow freely, but they should be syringed twice a day. Shading will be necessary only when very bright sunshine prevails, for plenty of light causes the colours to develop. As soon as the small pots are well filled with roots they should be re-potted into larger receptacles. Provide plenty of drainage material, and as a compost use a mixture of loam, leaf-soil, peat, and sand in equal portions. No manure should be used in the potting medium, for it is much better to feed with liquid manure after the pots are filled with roots. Place the plants in a light position in a house with a temperature of 65° to 70°, and if the pots are plunged in bottom heat it will be an advantage. When fully grown they may be removed for a time to a warm greenhouse, but the temperature should never be allowed to fall below 55°. As soon as the foliage begins to fade water must be withheld from the roots and the plants be removed to a dry and warm house. They are best wintered in a dry place in the plant stove.

THE FLOWER GARDEN.

By W. Fyfe, Gardener to Lady Wantage, Lockinge Park, Berkshire.

Pruning.—Flowering and other shrubs that are cultivated for winter effect may be pruned during the present month. It will be necessary, however, to leave the more tender species, as, for instance, the Golden Elder, until the last. In cutting back the shoots leave about 3 inches of last season's wood. The result of this annual cutting back is to obtain stronger growth and finer colour in the foliage and wood. Many of the Spiræas may be cut back every year with advantage; so may Hydrangea paniculata, Euonymus europæus, Tamarix japonica, Cornus sanguinea, Prunus Pissardii, and numerous Willows, &c. Such flowering shrubs as the Almond, Crataegus, Prunus, &c., may be pruned much upon the same principle as Pears, Plums, Cherries, and Peaches. Owing to the natural habit of many of the best shrubs being what is desired, they should be pruned very lightly or not at all. Such are Berberis stenophylla, B. vulgaris purpurea, B. dulcis, B. Darwinii, B. japonica, and B. Thunbergii. Evergreen shrubs such as Aucubas, Box, Privet, Laurel, Berberis Aquifolium, Yew, &c., should be examined every season for the purpose of keeping them as near as possible to their natural character, and prevent them from encroaching upon the space needed by weaker growing plants. If the shrubs are given proper attention they will be the better fitted to withstand severe weather or heavy falls of snow. On the morning of March 3 there was a fall of 3 inches here, and on March 4, 5 inches; on March 5 there was 12° of frost. The snow pressed heavily upon tender subjects until relieved by shaking. Many large boughs of Elms fell to the ground from the weight of snow.

Flowering shrubs not yet to be pruned.—Such species as Weigela, Honeysuckle, Ribes, Hypericum, Philadelphus, and Kerria, are best pruned after they have flowered, but the pruning should consist in simply removing, if necessary, some of the older wood. A variety of Kerria known as variegata is distinct, having a slender habit and green, yellow, and white variegation. It may be grown under partial shade, and the variegation will be preserved.

The perennial Phlox.—As soon as the plants commence to grow, a good mulching of well-rotted manure should be applied over the roots. This is the best time to propagate the plants. Each clump will produce so many shoots from the base that they will benefit by being considerably thinned. When these shoots are from 2 to 3 inches long they may be employed as cuttings. Each cutting should be potted into a thumb pot, which should be plunged in a gentle heat. When they have made roots repot them into 5-inch pots, and each plant will produce a handsome spike of flowers at about August if grown in a position out of doors fully exposed to the sun.

THE ORCHID HOUSES.

By H. G. Alexander, Orchid Grower to Major G. L. Holford, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Miltonias.—The species M. vexillaria and its varieties thrive best in a cool intermediate house. At the present time the flower-spikes are visible in the partially-developed growths, and the latter are pushing forth new roots freely. The plants, therefore, will need more moisture both at the root and in the atmosphere than hitherto, and the foliage should be freely syringed daily with tepid soft water whenever the weather is bright. This treatment will benefit the plants and help to prevent the multiplication of thrips, a troublesome pest, especially the small yellow kind, which is very partial to Miltonis. Before the flowers commence to expand, mild fumigations of the house at about every ten days with some safe vaporising compound will be useful. If thrips were not kept under they would attack the foliage and flower-buds in their tender stage, causing disfigurement. Some experts advocate the repotting of M. vexillaria at about the present stage, but I prefer to leave them until after the flowering season.

M. Roezlii and M. Bleuana. The culture of these plants should be very similar to that afforded M. vexillaria, except that M. Roezlii requires more heat, and should, therefore, be placed in a shady corner of the warmest house. M. Bleuana is a hybrid from M. vexillaria and M. Roezlii and should be grown in an intermediate temperature. Repotting is best done when the new growths are a few inches high, and they are making new roots. Avoid overpotting, as the plants give better results when the roots are confined.

M. spectabilis and its varieties, M. Regnellii, M. candida, M. Clowesii, and others that flower late in summer and autumn, all require a warm atmosphere. These can usually be accommodated in the Cattleya house, selecting the shadiest part for them. The plants are now making their growth, and when the new growths are about to make a fresh batch of roots, new rooting material may be afforded to any of the plants that require it. Plants of this section having creeping rhizomes require considerable space to permit of extension, and the rhizomes should be kept pegged down to the material as fast as they extend. Pans are the best receptacles for these plants, and as copious supplies of water are necessary during their season of growth, perfect drainage should be afforded and only a thin layer of compost employed. The compost may consist of Polypodium fibre, Osmunda fibre, and clean fresh sphagnum-moss in equal parts. Mix these materials well together and press the compost firm about the roots.

Sophronitis grandiflora.—This highly-coloured little epiphyte thrives best in shallow pans suspended from the roof rafters, and succeeds well with quite cool treatment. A light position should be afforded, but the plants should never be exposed to bright sunshine. If repotting is necessary, it is best done immediately after the flowering, as new roots are then being made by the partially-developed growths. These plants grow freely in a compost similar to that previously advised for Cattleyas, putting plenty of drainage beneath it and fixing the roots firmly in the material. Afford a liberal supply of water to the roots during their growing season.

THE HARDY FRUIT GARDEN.

By F. Jordan, Gardener to The Dowager Lady Nunburnholme, Warter Priory, Yorkshire.

Bush fruits.—If the Gooseberry bushes have been left unpruned owing to the fear of damage by birds, the work cannot be longer deferred, but must be pushed to completion as soon as possible. Some cultivators deliberate as to whether they should prune before the sap is in motion and the buds swelling. If the work is postponed to that stage greater care has then to be taken or many of the buds will be broken away from the shoots. There are many methods of pruning the Gooseberry, but the primary point to bear in mind is the need there is for so shaping the bushes that light and air may easily circulate through them, as these conditions are most conducive to fertility. Commence pruning by removing the shoots from the centre of the bushes, shortening the leading shoots but little, excepting those which are likely to hang too near to the ground. When the centre is made sufficiently open, examine the bushes all round, and remove any shoots that cross with each other, or any that are too thickly placed, removing the tops of shoots here and there to secure a uniform bush. Dessert varieties require rather more severe thinning in order to obtain fruits of the best quality. It is not yet too late to plant, but care should be taken to do the work when the soil is in proper condition. In choosing a site and varieties, have regard to providing for succession of crops, so that a regular supply of fruit may be ensured as long as Gooseberries last. Method should be observed in the planting, keeping each variety together, in order that greater convenience will follow when netting and gathering of the fruit becomes necessary. Early autumn is doubtless the best time to plant, but for various reasons it is often necessary to postpone the work until spring.

Currants.—These are most accommodating as to soil and situation, and even when Gooseberries are cut by late spring frosts the Red Currant in particular is almost certain to bear a good crop. Early and late varieties should be planted in a similar manner as recommended for Gooseberries, to furnish an early and late supply for kitchen purposes. A few bushes of the white-fruiting variety should be planted, as these are appreciated when thoroughly ripe for dessert; when planted as double or treble cordons against north or west walls, and protected from wet and birds, they will keep in good condition until November. In pruning, shorten the shoots back to about two buds, and the leading shoots to 6 or 8 inches.

Black Currants have not been so reliable in recent years owing to the injury caused by Currant bud mite. No variety seems immune from this pest [Boskoop's Giant is commended as being less liable to attack], which makes clean stock more difficult to procure. The simple operation of pruning consists in the annual thinning of the old shoots to let in light, and others which cross, allowing the young growths to develop.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents.—*The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

Local News.—*Correspondents will greatly oblige by sending to the Editor early intelligence of local events likely to be of interest to our readers, or of any matters which it is desirable to bring under the notice of horticulturists.*

APPOINTMENTS FOR THE ENSUING WEEK.

TUESDAY, MARCH 17—
Roy. Hort Soc. Coms. meet. British Gard. Assoc. Ex. Council meet.

THURSDAY, MARCH 19—Linnean Soc. meet.

SATURDAY, MARCH 21—German Gard. Soc. meet.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—41·9°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, March 11* (6 P.M.) Max. 48°; Min. 40°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, March 12* (10 A.M.): Bar. 29·9; Temp. 42°; Weather—Fair.
PROVINCES.—*Wednesday, March 11* (6 P.M.): Max. 48° Cornwall; Min. 41° England N.E.

SALES FOR THE ENSUING WEEK.

MONDAY AND WEDNESDAY—
Sale of Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

MONDAY AND FRIDAY—
Herbaceous and Border Plants, Lilies, and Hardy Bulbs, at 12; Roses at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

WEDNESDAY—
Perennials and Border Plants, Hardy Bulbs, &c., at 11.30; Roses and Fruit Trees at 1.30, Azaleas, Palms, &c., at 5; 760 cases Japanese Lilums, received direct, and 1,000 Miscellaneous Plants, Bulbs, &c., at 1.30, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

FRIDAY—
Vanda Cœrulea, Burmese Dendrobes, Established Orchids, &c., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 12.45.

Clover Sickness.

The farmer who cultivates arable land is only too well acquainted with "Clover-sick land," for although red Clover is perhaps the most remunerative crop that can be produced both for its return as hay and for the improvement it effects in the fertility of the soil, yet on few soils can it be grown with success more frequently than once in four, five, or even seven or eight years. If Clover be sown at shorter intervals it grows freely enough until winter, when, as a rule, it is killed off to such an extent as to be worthless as a crop. The severity of the winter seems to have little to do with the amount of damage, nor has the richness of the soil or the cultivation it has received any marked effect upon the result. At Rothamsted attempts have been made since 1849 to grow Clover and other leguminous plants year after year on the same land, but the extent of the failure may be seen from the following figures for one of the plots where a complete manure, including phosphates, potash and nitrate of soda was used. In 1849, the first year, about 4½ tons of Clover hay per acre were obtained; a crop of Wheat was then taken and the Clover re-sown; in 1851 the yield of hay was only about one ton, rising to rather more than two tons in 1852, and followed by complete failure in 1854. During the next 20 years a crop of Clover was only obtained on four occasions, and each time between one and two tons only of hay were obtained; on five other occasions Clover was sown and failed completely; nor has any measurable crop been obtained since that time, though every other year an attempt is made to grow Clover, a bare fallow being taken as a preparation. The nature of the manures applied to the various plots made no essential difference to the results; where large quantities of potash were used the Clover was always better, but as far as could be seen no kind of manure would enable the land to carry Clover continuously. The only success attained in this direction at Rothamsted has been on a little plot, now on the lawn in front of the house but originally a piece of a rich border in the kitchen garden, where Clover has been grown with only one or two failures every year since 1854. The crop is now very weak and has to be frequently re-sown, but as lately as 1905 two cuts yielded at the rate of 23,000 lbs. of green stuff per acre, equivalent to more than 2½ tons of Clover hay per acre.

The destruction of the Clover plant in the winter was formerly attributed to an eelworm (Tylenchus devastatrix) in the soil, but whether this is ever a contributory cause or not, in most cases the plant is found to be attacked by the fungus Sclerotinia trifoliorum, which invades the crown and central stem of the plant and leaves behind in the degraded tissues the characteristic little black sclerotia, which form a resting stage of the fungus. So far, then, the case seems simple enough; in the Sclerotinia we have a fungus destructive of Clover and one which leaves the land infected with its resting spores, so that the land must be cropped without Clover for several years until the fungus has disappeared from the soil.

There are several reasons, however, for regarding this theory of Clover sickness as incomplete; admitting the fact that Sclerotinia effects the destruction of the Clover, it does not explain why Clover growing on land that has recently carried a healthy crop should thereby become more susceptible of infection. Air-borne spores are certain to drift on to the normal crop on healthy land, yet as far as has been observed infection does not take place, and when the Clover field is ploughed up in the autumn no sclerotia are left in the soil. In the ordinary course it is a healthy and not a diseased crop residue which is ploughed under, and though Sclerotinia will grow in the laboratory on dead Clover stems it has not been shown that the residue of dead Clover plants left in the soil become infected during the autumn and winter following the growth of the Clover crop so as to leave the ground full of sclerotia. Thus evidence is lacking for two points essential to the ordinary theory of Clover sickness: that a healthy Clover crop leaves behind sclerotia in the soil and that the origin of the infection which destroys the crop on Clover-sick land is sclerotia in the soil and not air-borne spores.

If mere infection is really the cause, why should Clover have remained healthy so much longer on the garden soil at Rothamsted than on the arable land? Sclerotia in scores have been picked out of the soil of this plot at one time, and can be found there abundantly enough to-day, yet the Clover manages to survive—weakly, indeed, but on the similar plots on the arable land it never survives the winter at all.

Again, Clover that is growing mixed with grasses continues indefinitely on the same soil without showing signs of infection. At Rothamsted, for example, on the permanent grass plots that are manured exclusively with mineral salts without nitrogen, more than half the vegetation is made up of leguminous plants, Lathyrus pratensis, and White and Red Clover being the chief species. Under these conditions no Clover sickness is apparent; similarly on the narrow strips of grass dividing the arable plots which refuse to grow Clover, both White and Red Clover plants are abundant and show no signs of dying out. As they must be exposed to contact with the spores of the disease we can only conclude that Clover plants living in grass land do not become predisposed to Sclerotinia infection.

Another fact of importance is that the crop on Clover-sick land sometimes escapes infection and destruction during the winter, when, however, it only continues to grow in a weakly fashion and yields badly. A good example of this was seen at Rothamsted, when parts of the plots on which attempts had been made to grow various leguminous crops for many years were ploughed up, and after five crops of Wheat were sown with Clover, Vetches and Lucerne in breadths extending across the old plots. Where the new Clover plot crossed the old ones the growth was weaker than elsewhere, although no disease was seen; similarly the Vetches were weaker where they came on the old Vetch plots, and the Lucerne showed the same weakness without disease where Lucerne had been growing previously. These facts would suggest that Clover sickness is only a special case of a more general phenomenon—the way the growth of any crop more or less unfits the land to carry the same crop again in the following season.

At Rothamsted Wheat has been grown for 64 years in succession upon the same land without much falling off in yield where a complete manure has been supplied; similarly Barley has been grown for 55 years and Mangolds for 32 years on the same land. But a decline in yield of the Barley, at any rate, can be traced, even if this is doubtful in regard to the Wheat, and it must not be forgotten that Lawes and Gilbert failed to induce Swede Turnips to grow for many years on the same land. Other crops other than those of leguminous plants are reputed to render the land quickly "sick," e.g., Flax and Strawberries; on the contrary every practical cultivator knows with what vigour a crop starts on land that has not produced a similar one before, just as the value attached by a gardener to "maiden loam" is not solely a question of the plant food it contains. There is thus some reason to suppose that in considering the benefit derived from a rotation of crops some unexplained factor exists, in that any crop does in some way injure the soil for the growth of the same crop in the following season, certain crops being much more potent in this way than others.

According to this view, when Clover is sown on land that has carried Clover not long before it becomes so weakened that it falls a ready prey to any spores of Sclerotinia which

may reach it, although it can resist the attack of these spores when it is growing on healthy land.

How the plant can injure the soil for its own renewed growth is still a matter of speculation; Dr. Whitney and his colleagues of the Division of Soils of the U.S. Department of Agriculture consider that the plant actually excretes substances toxic to itself, thus reviving one of the oldest theories regarding the rotation of crops, but their conclusions have not as yet found any general acceptance. Two French observers, Pouget and Chouchak, consider that the bacteria in the nodules of leguminous plants excrete compounds injurious to fresh plants, and bring forward an experiment to show that if Lucerne be watered with an extract from soil in which Lucerne had long been growing its yield is depressed. But in their experiments only four pots seem to figure and the yields are so small that it is very unsafe to draw any conclusions from them; in consequence their theory must be regarded as still entirely a matter of speculation. Other possible hypotheses may be advanced, such as the supposition that the bacteria in the nodules of the leguminous plants may by continued growth in the plant pass into a quasi-pathological condition and act as parasites (it is an observed fact that Clover plants on Clover-sick land form nodules freely and are not suffering for want of inoculation), but pending the results of a series of trials that are now in progress it would be idle to discuss the numerous possibilities. However, to the author, it seems that the fungus Sclerotinia trifoliorum is only the proximate cause of the death of the Clover plant, the ultimate cause of Clover-sick land is still to seek.

OUR SUPPLEMENTARY ILLUSTRATION.—One of the most interesting and valuable sections into which winter-blooming Begonias may now be divided is the type which Messrs. JAMES VEITCH & SONS have raised by crossing the tuberous-rooted varieties with Begonia socotrana. The first hybrid was distributed in 1885 under the name of John Heal, in compliment to their skilful plant-breeder, whose successful work is illustrated in these Begonias as in many other plants. Since that time a considerable number of varieties have been first exhibited at the shows and subsequently distributed in gardens. The variety Mrs. John Heal was sent out in 1895. The flowers are about 2 inches wide, the petals equal and overlapping, rich rosy-red, produced freely on plants 1 foot high (see fig. 71). In the Supplementary Illustration is shown a batch of plants which were cultivated at Eshton Hall, the residence of Sir M. WILSON, Bart., and they represent such successful culture we have pleasure in reproducing the following information kindly supplied by Mr. LEON SQUIBBS, the gardener at that place. "The cuttings were taken in March, and inserted in a compost of peat moss in the stove. As soon as they had made roots, each plant was potted singly into a pot 3 inches in diameter, using a potting compost of loam, leafmould, peat, and sand in equal proportions, all the materials having first been passed through a ¾-inch sieve. When they had rooted sufficiently, they were re-potted into pots 5 inches in diameter, the compost being fibrous loam, leafmould, and peat in equal parts, with some dried cow manure and a little sand. They were finally potted into 7 and 8-inch pots, a similar compost, with a little soot and bone meal added, being again used. The plants were cultivated in a moist stove atmosphere from start to finish, but they were shaded from hot sunshine. They were watered twice weekly, either with liquid manure from the farmyard, or after an application of Clay's fertiliser, and occasionally with soot water. All the flower-buds that appeared before September were pinched off, but after that time the plants were allowed to flower. Many of the sprays were 1 foot to 1 foot 6 inches, and the bloom 2 inches in diameter. It is advantageous to remove the plants into a house of intermediate temperature after they have developed a considerable number of flowers, as this ensures a longer period of blooming, and the plants are rendered more serviceable for house decoration; they have proved invaluable here for this purpose. Begonia Mrs. Heal surpasses Gloire de Lorraine in effectiveness. This latter Begonia is given the same treatment, and the plants have measured 3 feet in diameter and as much in height." It may be added that this type of Begonia, combining as it does characteristics of the tuberous-rooted and fibrous-rooted species, needs to be treated very

FIG. 70.—BEGONIA SOCOTRANA HYBRID.
(Showing growths from axils of leaves, and formation of tuber at base of stem.)

carefully as soon as the flowering season is past. At fig. 70 is reproduced a photograph showing the condition of a plant as it should appear at about March 1. At that time the plants are busy forming tubers, as the tuberous species would do, and also producing growths from the axils of the leaves, which is a characteristic of the fibrous-rooted species. They should be kept in a warm, freely-ventilated house, and watered sparingly about once each week. The culture should be directed to getting the tuber to swell properly and to mature fully, for which purpose it is necessary to keep the leaves healthy and green as long as possible. When the young growths from the axils of the leaves have become long enough, they may be removed for use as cuttings for the increase of stock. At the beginning of the month of June, the plants should be cut down to about 2 inches from the base, and they may then be cultivated for another season, but should not be hastened into growth by exciting culture.

ROYAL HORTICULTURAL SOCIETY.—The next meeting of the committees will be held on Tuesday, March 17, in the Society's Hall, Vincent Square, Westminster. A lecture on "Beautiful Flowering Trees and Shrubs" will be delivered by Mr. G. GORDON, V.M.H.

FRIEDERICH LUCAS.—On February 9 the business manager of the German Pomological Society, FRIEDERICH LUCAS, of Reutlingen, was presented by his friends with a honorary gift. When Herr LUCAS resigned his office on April 1 last year, after a service of 20 years, the wish was expressed in horticultural circles in general to do honour to the man who had accomplished so much, both by his literary work and by his long-continued services in the improvement of fruit-growing among German-speaking peoples. Donations were subsequently received from all quarters of Germany, Austria, Switzerland, and other countries, insomuch that not only a writing table and chair were purchased, but a sum of 1,290 marks remained over, which will form a memorial fund, the "FRIEDERICH LUCAS Stiftung," the interest on this sum being expended in premiums to deserving students of the Pomological Institute of Reutlingen, as Herr LUCAS himself may decide.

BOTANICAL MAGAZINE.—The March number contains illustrations and descriptions of the following five plants:—

SINNINGIA REGINA, tab. 8182.—This fine purple-flowered variegated-leaved plant is closely related to S. speciosa, the wild ancestor of the cultivated Gloxinias. Nothing more is known of its habitat than that it was brought from Brazil by Mr. DE SMET-DUVIVIER, a nurseryman in Ghent. It was described in the *Gardeners' Chronicle* (Vol. xxxvi., p. 87) in 1904. The stem springs from a stout tuber, and the flowers are pendulous from short peduncles, about 15 to 20 blossoms being expanded at the same time. The cultural requirements are the same as those of Gloxinia; the plant seeds freely, and cuttings of the leaves may also be used for its propagation.

CYPRIPEDIUM DEBILE, tab. 8183.—This is a pretty little plant, not very showy, as green is the prevalent colour of the flower; the petals and sepals have, however, a brown blotch at the base, and the lip mostly white streaked with brown. It is suggested that it may be sufficiently hardy to be grown in the open, but it would require one of the higher ledges of the rockery to display its rather modest charms when it flowers in April. (See fig. 166 in *Gardeners' Chronicle*, December 23, 1905.)

PYRUS ARIA VAR. MAJESTICA, tab. 8184.—Many varieties of the White Beam tree are known, and the subject of this illustration is growing in the Kew Arboretum, where it flowers and fruits freely almost every year. The origin of this, one of the finest varieties of the species, is unknown, and it is regarded as probable that it originated in cultivation.

BERBERIS ACUMINATA, tab. 8185.—Like so many of the Barberries, this species hails from the East, having been discovered by DELAVAY in China (Yunnan) in 1882. It has since been found by Dr. A. HENRY and Mr. E. H. WILSON in the mountains of Western Hupeh, where it seems to occur at an altitude of 5,000 to 6,000 feet above the sea. The specimen for the illustration was supplied by Messrs. JAMES VEITCH & SONS, and was raised from seeds collected by Mr. WILSON, the plants flowering last May at Coombe Wood. The leaves of the evergreen shrub are lanceolate and spinous-serrate, the yellow flowers are borne on red stalks in fascicles of, usually, five to nine, and are followed by black berries with a glaucous bloom.

ROSA WILLMOTTIÆ, tab. 8186.—This beautiful simple Rose was raised by Messrs. JAMES VEITCH & SONS from seeds collected in Western

China by Mr. E. H. WILSON. It forms a shrub 5 to 10 feet high, and is nearly glabrous, with slender red-brown branches. The leaves are crowded and each bears about nine leaflets. The flowers are purple-rose, about 1 to 1¼ inch across.

CIGARS FROM LONDON GROWN TOBACCO.—We extract the following remarks from our contemporary, *Tobacco:* "Cigars made from Tobacco actually grown in London appear an impossibility and an absurdity, but in reality they are neither. A portion of the 1906-7 London Tobacco crop, grown experimentally at Regent's Park for the last International Tobacco Exhibition, has been manufactured. The plants were shown at the last Tobacco Exhibition—at the next, which takes place on the 21st inst. at the Royal Horticultural Hall—the cigars themselves will be shown. For the first time a representative selection of commercial seed from Cuba, America, Germany, and other Tobacco-growing countries has been brought to maturity on English soil. Tobacco growing is looming large just now as a first-class problem for Parliament. Ireland has wrested her charter of liberty in this respect from the Government; Scotland has already put forward a Bill for similar emancipation. And now, after all this, we have at one sweep the London-grown and London-cured leaf and the cigar manufactured therefrom. These cigars, let us hasten to add, are smokable, though a certain measure of patriotism and London pride is required to rise to the level of their aroma and taste. But one thing they are, and that is honest. They may be described without offence under the Merchandise Marks Act as the 1906-7 London crop, and as English all through, wrapper, 'bunch,' and filler. In order that the British public may see what London can do in the way of Tobacco growing, it has been arranged to make a special exhibit of these cigars at the Tobacco Exhibition as part of a display in which the pick of United States and Colonial leaf will also be included. They will be labelled Flor de London."

BIRDS AND SPANGLE-GALLS.—The *Kew Bulletin* (1908, No. 2) contains an interesting note showing that certain birds will eat the common spangle-galls, which form the well-known red plate-like bodies on oak leaves. These galls were found in the crop of a grey-hen, a black-cock, and a pigeon. It would be interesting to know whether they are of any nutritive value to the birds, or whether they are only picked up by them in mistake for seeds.

FIG. 71.—BEGONIA "MRS. HEAL": FLOWERS ROSY-RED.

Linnean Society.—A meeting will be held on March 19, at 8 p.m., when the following papers will be read:—The Rev. Canon Norman, F.R.S., F.L.S., &c., "The Podosomata of the Atlantic and the Arctic Oceans"; Mr. T. F. Chipp, "A Revision of the Genus Codonopsis"; Mr. E. Hindle, on the "Holothurians from the Red Sea."

Conditions of Employment at Kew.—We learn with satisfaction that one of the new regulations affecting the journeymen gardeners at Kew has been rescinded. The old practice was that men who had completed the two years' term as journeymen should be allowed to remain until they had obtained situations elsewhere, unless, as sometimes happened, they were not quite up to the mark. Such an arrangement was fair to the men; it encouraged effort, and it was advantageous to the gardens. The Board of Agriculture, however, recently decided that the term must be strictly limited to two years, with the result that something like a dozen men might have been thrown out of employment in winter. There is no garden, either public or private, where such a hard-and-fast rule is enforced, and the revision of the decision on the part of the Board cannot fail to meet with general approval. In answer to a question asked in the House of Commons on March 5 by Mr. Summerbell, member for Sunderland, it was stated that "the men who had completed their two years' term would continue to be employed until they had obtained situations elsewhere, provided that they continued to give satisfacion and that they used their best endeavours to find other situations."

Presentation in a Glasgow Park.—Mr. Gavin Prentice, who has been park foreman in Glasgow Green for the long period of 38 years, was presented on the 7th inst. with a purse of sovereigns from the parks' staff and interested friends on the occasion of his retirement. The presentation was made on behalf of the subscribers by Mr. Whitton, parks superintendent, who, in doing so, briefly recounted what had been done to improve the condition of the Green during Mr. Prentice's tenure of office, and said that nearly every tree and shrub now existing there had been planted under his supervision. Mr. Whitton then introduced Mr. Jeffrey, who has been for nearly 11 years outside foreman at the Botanic Gardens, and has been appointed to succeed Mr. Prentice.

Death of Mr. E. J. Castle.—Mr. E. J. Castle, a well-known horticulturist and writer, died at Lyminge, Kent, on March 4, at the early age of 39 years. For some time deceased was associated with Mr. Walter P. Wright in editing *The Gardener*, but removed to Lyminge owing to ill-health.

American Gooseberry-mildew.—At the Downham (Norfolk) Police Court on the 2nd inst. a fruit-grower was fined £10 for having on February 14 failed to adopt such measures for the prevention of the spread of the American Gooseberry-mildew as were specified in a notice served on him under Article 6 of the Order of the Board of Agriculture and Fisheries.

Bulbs failing to Bloom.—Complaints have been almost universal this season over the uncertainty of many bulbs, especially Hyacinths, to produce a good crop of flowers. The trouble has been felt as much abroad as in this country, and in many of the Continental journals we constantly meet with similar expressions of disappointment. Even in Holland and Belgium the same tale is told, and the cause doubtless is to be attributed to the exceptionally unfavourable summer of 1907, which prevented the proper ripening up of many bulbs, and thus caused a number of inferior ones to find their way into the markets.

Are Olives Fruits?—According to a paragraph in our contemporary *Le Jardin*, the Italian Government some two years ago, under a law prohibiting the importation of vegetables, refused to allow a consignment of Olives from Greece to enter the country. It required an action at law to decide that Olives are fruits, and the Italian authorities were mulcted in 400,000 francs damages, as well as in costs, for having acted on the supposition that they were merely vegetables.

Lilac Trees.—Lilacs are so well known for their troublesome habit of producing suckers, that the notice of the Rumpenheim Lilacs in the current number of the *Kew Bulletin* is of some interest. For many years a pair of Lilacs grew in the gardens at Cambridge Cottage (the residence at Kew of the two last Dukes of Cambridge), which formed clean trunks and produced no suckers. The larger trunk was 4 feet 2 inches high and 2 feet in girth. It is suggested that the plants, which were brought from Rumpenheim-on-the-Main, near Frankfort, were originally raised from seed and not from cuttings, as is more commonly the case, and that the lack of suckers may possibly be attributed to this circumstance. Since the death of the late Duke in 1904 the trees have been moved, one of them to Windsor, the other to the lawn in front of Kew Palace.

Fig. 72.—View in the Primula house at Messrs. J. Carter and Co.'s nursery.

NURSERY NOTES.

Messrs. Jas Carter & Co., Forest Hill.

At the present time Chinese Primulas are the chief feature in the nursery at Forest Hill, several large houses being filled with plants in full flower. They do not appear to be grown very strongly, but this may be an advantage, seeing that they are cultivated expressly for the production of seed. We noticed in one house a selection of a few plants of each colour specially set aside for cross-fertilising, and for producing seed for cultivation by the firm itself. But in the larger batches also, all the flowers were remarkably true to colour, and the plants possessed an equally good habit. Several distinct types were noted. One termed Bouquet had flowers of large size and a leafy development beneath each whorl of blooms.

Of white varieties, King Edward was one of the finest, but Elaine, a Fern-leaved variety with dark leaf stalks, is also a good one. Holborn Queen is pure white, with pale green foliage, and Princess May, a very fine blush-coloured flower, borne on bold trusses. Holborn Blue showed great improvement on the original type, and varieties of paler shades of blue and mauve were also observed. The variety Holborn Coral may be specially referred to as being of remarkable substance and a most pleasing shade of coral pink. The deep red varieties showed great advance on the original Chiswick Red, which has proved of so much value to breeders of Primulas.

The semi-double varieties are now procurable in most of the shades of colours found in the single flowers. Snowflake was the best white variety, being of good habit, with several whorls of flowers above each other. Prince of Wales is a lovely shade of pink, and the red and scarlet varieties were very bright.

In some of the houses the results of careful fertilisation with the brush were apparent, there being every indication of a good crop of seed. A separate brush is kept for each variety, and this effectually prevents any undesirable crosses being made.

The stellata varieties are kept by themselves, and in these the colours were very decided, several having a dark zone around the eye being very pretty. One variety of a bluish-mauve shade was distinct, and the bright crimson and vermilion shades were worthy of special note. A batch of plants with pure white flowers presented a mass of blossoms.

Cinerarias are also extensively grown for seed purposes. In one large house, which was filled with plants of the best florist's type, a few of the first flowers were opening, and a little later they will make a fine show. In another house the stellata type was well represented. The Cactus-flowered varieties were further advanced than the ordinary type, and showed that the plants will come very true from seed.

Herbaceous Calceolarias receive careful attention, and a large batch of plants was well advanced in growth. Gloxinias, tuberous Begonias, Petunias, &c., were being prepared to fill the houses after the present occupants have yielded their seed harvest. A.

THE FRANCO-BRITISH EXHIBITION.

By the courtesy of the secretary of the Franco-British Exhibition, which will be held at Shepherd's Bush, we are enabled to publish an illustration (fig. 73) of the exterior of the "Garden Club." The building has a frontage of 300 feet, and a depth of over 130 feet. The club will be under the direction of a committee, presided over by the Earl of Jersey, and including, among others, Viscount Selby, Lord Alverstone, Lord Blyth, Lord Desborough, and Lord Strathcona. Further particulars of the accommodation provided by the building and the conditions of Club membership were printed in our issue for February 1, p. 73

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

The Recent Colonial Exhibition at Westminster.—It is greatly to be desired that before the Royal Horticultural Society holds its next exhibition of Colonial produce in June, that the authorities representing the several Colonies of the British Empire should, if they really appreciate the efforts of the Royal Horticultural Society, be far more energetic than was evidenced in connection with the recent show. What a remarkable contrast this Colonial Exhibition presented to the spectacle that was seen on the 3rd instant in the hall! It was at the best a poor and disappointing display, such as the promoters should have felt themselves humiliated to place before the public as representative of Colonial produce. It was easy to explain that much of the expected produce was delayed on board ship, but earlier shipping of the commodities would have prevented that incident. A feature which also needs the attention of the authorities is that such exhibits as those of the Army and Navy Stores, and some others, were quite heterogeneous in character and included produce from several Colonies not specified; thus they failed to furnish that particular information the public need. Every exhibit from any given colony should not only be staged as such under the control of the representative of that colony, but should have attached the name of the grower, the colony, and the district where it was grown. Home dealers, whether from London or elsewhere, should be excluded, because they are merely distributors, and not producers. *F.R.H.S.*

Cultivation of Species of Phormium.—Mr. G. B. Mallett, in his interesting article (in the issue of March 7) on the genus Phormium, gives as his experience that these plants thrive best and prove hardiest in sheltered and *well-drained* soils. He says "the cultivation of the various species of Phormium is solely a matter of light, *dry* soil and shelter." And again: "I should have no hesitation in planting P. tenax where I was certain of wind shelter and a *well-drained* soil." (The italics are mine.) I am surprised at this, for in its native country P. tenax (New Zealand Flax) is essentially a swamp, or, rather, an aquatic plant, for the New Zealand swamps are practically shallow lakes choked up with vegetation. It is in these swamps, often several square miles in extent, or in similar conditions, that P. tenax grows almost exclusively, thriving best and attaining its largest dimensions in about 1 foot of water, though it often grows in deeper water up to and over 4 feet deep. On the contrary, though isolated clumps may often be seen on the land, probably where folds or hollows of the ground favour a retention of moisture, they evidently are not at home there and, compared with plants growing in the swamps generally, have a stunted appearance. As a matter of fact, the Flax cannot hold its own on dry land against the Ti-tree and Bracken, and it is always noticeable how the serried ranks of the Flax end abruptly where the ground rises at the edge of a swamp. Nor is the climate so very mild in some parts where P. tenax grows. When surveying among the swamps at Okoroire (about 150 miles south of Auckland) one winter, there was a frost nearly every night for a month or more, enough to freeze the water in shallow pools, though ice never formed in the swamps, and the Flax was apparently not affected in the least. And P. tenax grows far south of this. It is true that it does not follow that the same conditions that suit a plant in its native country will be best for it in an English garden. The cultivation of exotic plants is generally a compromise. Nevertheless, P. tenax is so certainly a water-loving plant that I venture to suggest that growing it in dry and well-drained soil may result in a lack of vigour which renders it less able to withstand a low temperature, and so gives it the reputation of a lesser degree of hardiness than it really possesses. "The old-established clumps by the waterside in Edinburgh Botanic Gardens" that Mr. Mallett mentions are, I think, some support to this view. I think also that it is probable that it cannot stand much lime in the soil. Though I did not pay much attention to this point, it is my impression that there is no limestone formation of any sort in the Waikato district, where the great Flax swamps are, the whole area south of Auckland to Lake Taupo being chiefly of volcanic origin, and the swamp water is noticeably soft and generally strongly impregnated with iron. It was, I believe, largely owing to these same reasons (dislike of lime and a dry soil) that Iris lævigata was at one time thought to be deficient in hardiness, and it is a plant with a very similar semi-aquatic habit. Another very analogous case is that of Dierama (Sparaxis) pulcherrima. This grows in the Transvaal in marshy ground on the high veldt (much the same as the peaty bogs on the upland moors in this country). This plant also has the reputation of being half-hardy here, and certainly if planted in a light, dry soil, it does generally die out. But when planted in wet, peaty soil, or, still better, in a moderately stiff loam that holds the moisture well (and does not contain an excess of lime), it is perfectly hardy, flowering every year and increasing rapidly. *A. J. Bliss.*

Decorations at the Town Hall, Leeds. The Town Hall is a grand structure, and the principal apartment, viz., the Victoria Hall, is of great height and size. In this building, the Lord and Lady Mayoress recently gave a reception and dance to some 1,200 to 1,400 citizens and friends. The Lady Mayoress being a Canadian lady, the parks superintendent, Mr. A. J. Allsop, decided to give a Canadian aspect to his decorations. The large orchestra was studded and grouped with branches of Spruce, Scotch Pine, Larch, Swiss Pine, Birch and Alder in varying sizes. The floor surface was covered with common Bracken, and here and there patches of a strong-growing grass; out of this were (in what may be termed small glades) growing groups of Daffodils in variety

Fig. 73.—Exterior of "Garden Club" at the Franco-British Exhibition.

The idea was to suggest a portion of a Canadian forest, in which the musicians were to perform the dance music. On the front of the orchestra a small terrace was formed of white diamond trellising with stout pillars, on the tops of which were vases filled with Scarlet Pelargoniums. The trellis was daintily supplied with tall Pelargoniums also, all of them well furnished with flowers. In an open forecourt of this terrace, and level with the main floor space, were seats for the Lord and Lady Mayoress to receive their guests. Both sides of the main hall were furnished with diamond trellising for some 8 to 9 feet upwards, with recesses here and there for seats. In these the trellis was of a lighter character than the rest so as to give depth and variety. Over this trellis Ivy in variety was apparently growing from its base, with here and there some strong-growing pieces of Periwinkle furnished with scarlet berries, which suggested those of Pyracantha, and they were very effective. On the tops of this projecting trellis were groups of smaller Conifers, viz., Cupressus, Thuyopsis, Retinosporas in variety, with a natural admixture of Birch, large branches of Ribes and the ordinary Dog or Wild Rose. On the two latter were affixed quite naturally sprays of Crimson Rambler Rose (in imitation), the whole forming a beautiful picture when lit up in the evening. The large space under the gallery, which is at the opposite end to the orchestra, was grouped more or less in a similar way. The pillars that support the gallery were well furnished with strong-growing Ivy to imitate a natural tree. Out of these sprang in one case Birch branches naturally furnished with Rambler Roses, in another Dog Roses, and so on. Immense pieces of Bamboo were made the centres of groups of flowering and foliage plants worked out in a natural way. With the exception of Scarlet Pelargoniums, used for the terrace, the splashes of colour were mainly supplied by the Rambler Roses and Daffodils in variety. The idea and the way it was carried out gave great pleasure. *Yorkshire Gardener.*

Lilium giganteum.—The Rev. D. R. Williamson invites me to give my experience of the giant Lily, and I very willingly respond, albeit I have no secret to reveal, for this beautiful plant is among the easiest of its family to cultivate. It is about 40 years since a friend gave my father a couple of bulbs, which were at that time a novelty, and we have never been without the species since that time. The requirements of this Lily are fulfilled by a soil of good loam, with a liberal admixture of pulverised peat and some sharp grit, and a cool sub-soil. Shelter from parching winds in spring is essential, else the great, shining radical leaves, one of the chief beauties of the plant, get seared and torn. A woodland Lily,

it is usually recommended that it be grown in shade, but in the humid west it does best in full sunshine, although doubtless on hot soils in the south, as at Wisley, its growth is more vigorous among trees than in the open. Seed is produced in abundance, and germinates with the greatest freedom, but not until it has lain 12 months in the boxes. The bulbs take six or seven years before attaining flowering size. I have not tried Mr. Williamson's plan of mulching with farm manure, though it is easy to understand how growth in such a gross surface-feeder might thereby be stimulated to grander proportions. But I find that many flowering plants and shrubs, other than Lime-lovers, respond as freely to pure peat mixed with the staple as to anything else. The giant Lily is a grand subject for naturalising in woodland, but I have not yet tested whether its attractive foliage will escape the ravages of rabbits and hares. *Herbert Maxwell, Monreith, March 10.*

Grafting Varieties of Clematis.—The article which appeared in the issue for March 7 is interesting; but the writer does not touch upon a point of great importance, viz., "Is the hybrid Clematis more successful when grafted, or when cultivated on its own roots?" The failures that are so frequent and annoying are commonly attributed to the fact that the plants are not on their own roots; Mr. W. Robinson takes this view in *The English Flower Garden*, where he says: "The hybrid kinds are all grafted, and this is no doubt the reason why they die off like flies, and why these fine plants, of which hundreds have been raised, are so rarely seen well grown in gardens." I am not aware that the truth of this theory has been thoroughly established, my own experience having been inconclusive, and I think that the views of practical gardeners on the subject would be opportune. If gardeners could feel as sure of success with hybrid varieties of Clematis as, say, with Roses, they would have much less hesitation in planting them. Is the failure that suddenly overtakes the Clematis confined to grafted plants only? Are hybrid varieties of Clematis easily raised from layers, or does this depend on the particular sort that is being cultivated? *Harold Evans.*

Loss of Trees by Gale.—The gale that passed over England on February 22 effected much damage in this district. The storm was at its height at 3.30 p.m., and for about three minutes there was a perfect hurricane. The severity of the storm only lasted some 15 minutes, but for hours afterwards the wind continued high. Rain fell in torrents during the storm to the depth of 0.23 inch. During the three minutes already mentioned, some large Conifers, including Pinus austriaca, P. Cembra, P. Laricio, Abies excelsa, A. alba, &c., were uprooted; some of them were upwards of 60 feet in height, with a girth of from 3 to 4½ feet at 3 feet from the base. We had no fewer than 83 trees of this description uprooted, 57 of which stood on either side of a carriage road; the storm took a complete sweep through these 30 yards wide by 103 yards long, and did not leave a single tree standing. The scene of wreckage after the storm was a sight that one does not wish to see many times in a lifetime. This storm was the worst that it has been my lot to experience, notwithstanding that which occurred in Hertfordshire and Essex during the summer of 1897. *G. W. J., Kimpton Manor Gardens, Lincoln.*

Floral Arrangements.—Within the past few years the Gypsophilas, Statices, Saponarias, and other small flowers have, to a great extent, taken the place of green foliage in the arrangements of flowers for effect, and are regarded entirely as garnishing materials. This has led to many mistakes among the competitors at various flower shows, when, as in the case of Sweet Peas, Carnations, Chrysanthemums, &c., prizes are offered for decorations, and it is stated that no other flowers, but any foliage may be used. In such cases disqualifications have resulted through Gypsophila being introduced. In order to obviate this, the National Chrysanthemum Society have altered their rule, and in future where "other foliage" may be used, Gypsophila, Statice, and Saponaria may also be introduced in the arrangements. This alteration will undoubtedly be much appreciated by most exhibitors, and it is a rule which should be noted by other flower-show committees when compiling their schedules, for, in addition to the flowers named above, there are others which might cause trouble should the present rules be adhered to strictly. The Smilax, for instance, is often used while in flower. Asparagus Sprengeri is a more decided example, for though the flowers are comparatively inconspicuous, when present they add to the beauty of the greenery. The object of the restrictions has been to show the value of a particular flower when shown separately or with foliage, and it may be difficult, when other flowers are allowed, to draw the line. I have seen exhibits which have been disqualified through the use of Gypsophila, yet no notice has been taken of the use of Asparagus Sprengeri with flowers on the sprays. Experienced exhibitors should not need much advice, but I have seen quite old hands at exhibiting fall into errors through overlooking the fact that some rule has been altered. In preparing schedules, these small technical points should be given greater prominence, for there are always some among the defeated exhibitors who look them up. I remember once, when taking notes at a show, I was asked "Why should Asparagus Sprengeri in flower be allowed, while another exhibitor was disqualified because he had used Gypsophila paniculata?" I have referred to Saponaria, and as there are several species, it may be asked if all are admissible. I have not yet seen the rule in print, but it should be specified that it is Saponaria vaccaria and its white variety which are allowed. These are recent additions to the small flowers we see in Covent Garden Market. Last autumn the ordinary pink type was abundant. It has occurred to me that for the Chrysanthemum exhibits the Committee might have gone a little further, for during October and November the perennial Asters take the place of other small flowers. A. Tradescanti, A. vimineus, and A. ericoides include some pretty varieties with very small flowers on light branching racemes. It would perhaps be better to make a rule that where any special flowers are to be prominent, it should be left to the exhibitors to add any other foliage or small flowers as garnishing, and no disqualifications should occur, but judges could decide if the most had been made of the particular flowers, which should be the chief attraction of the exhibits. Or, it would be better still if the judges of the leading shows could meet and come to some definite arrangement which should apply to all shows, for at the present what is allowed at one show is disallowed at another, though the wording in the schedules regarding the rule may appear to have the same meaning. Disqualifications through some slight error dishearten new exhibitors, and though they may be clever at arrangements, they do not come forward again. In the Chrysanthemum exhibits there are other points which have to be considered; in one class the blooms shown in vases must not exceed certain dimensions. The exhibitors may keep within the bounds when arranging their exhibits, yet before the judges go round some flowers may fall over a little and exceed the dimensions. Disbudding, or, rather, "not disbudded" blooms is another question which has two sides. An amateur with a limited stock to select from may have to take some sprays of blooms from which it is necessary to remove certain flowers which have been damaged in some way; it may be that they have been disfigured by caterpillars or other insects, or, perhaps, damaged by wind or a little overblown. If the rule "To be shown as grown" is taken literally, no disfigured flowers can be removed, and this is a disadvantage to the exhibitors, and it also detracts from the beauty of the exhibits when viewed by visitors to the shows. During the past season the question of disbudding has been made a prominent feature at Chrysanthemum shows, and the decision that the flowers must be shown "as grown" in the "not disbudded" classes requires amendment. *A. Hemsley.*

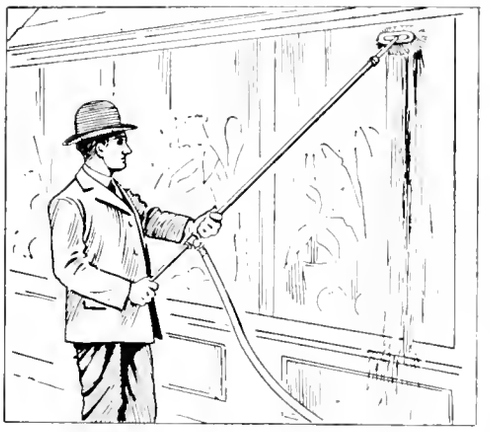

Fig. 74.—A window washing apparatus.

Poisonous Compounds for Horticultural and Agricultural Purposes.—It is satisfactory to find that the "Poisons and Pharmacy Bill" successfully passed its second reading in the House of Lords on the 5th inst., and was referred to a Joint Committee of both Houses of Parliament. The horticultural trade is materially interested in this Bill, as by Clause 2, power is given for persons, other than chemists, such as nurserymen, seedsmen, and agricultural agents, to stock and sell (under provisions to be made by the Privy Council) weed killers, insecticides, sheep dips, &c. It will be remembered that the "Traders in Poisonous Compounds for Trade Purposes Protection Society" has for years past been working to this end, and it is due to the efforts of the society that this clause has been inserted in the Bill. All those interested in the sale of these compounds should assist the society in its efforts to get Members of Parliament to support Clause 2 of the Bill, so that the same may become law this Session. *G. H. Richards.*

WINDOW WASHING APPARATUS.

An appliance similar to that illustrated at fig. 74 and manufactured by the Foley Manufacturing Co., Chicago, has recently been figured in the American horticultural journals. The water is supplied direct to the bristles of the brush by means of an attached hose, the supply being easily regulated by means of a small stop-cock. By its use, says our contemporary *Gardening*, the necessity for a pail and often a step ladder and other impedimenta are done away with, while the continuous flow of clean water swills the dirt right away, none of it being carried to the pail on the brush, as in the older methods. The brushes are made of water-proofed wood, and hand-stitched with non-rusting brush wire. The handle is made of galvanised steel, reinforced by a hollow wooden handle, which makes it impossible to collapse even if stepped on. Each one is equipped with a pair of ¾-inch standard hose couplings, and can be readily attached to any garden hose. It is made in three lengths, 6, 8, and 10 feet, but the brush can also be detached from the handle and attached to hose for washing wagons, carriages, or live stock, &c.

SOCIETIES.

ROYAL HORTICULTURAL.

Scientific Committee.

March 3.—*Present:* Sir John T. Dillwyn-Llewelyn, Bart. (in the chair); Prof. G. S. Boulger, Rev. W. Wilks, Messrs. A. W. Sutton, R. A. Rolfe, J. Douglas, J. T. Bennett-Poe, C. T. Druery, de B. Crawshay, G. Massee, G. S. Saunders, W. Cuthbertson, G. Gordon, W. Hales, A. Worsley, E. M. Holmes, S. Pickering, F. J. Chittenden (secretary), and numerous visitors.

Inheritance of albinism in Orchids.—The following communication was received from Mr. C. C. Hurst, F.L.S.:—Two distinct and definite cases of albino Orchids producing coloured forms when crossed were recently brought before this Committee by Mr. H. J. Chapman. Such facts expected by the Mendelians, are important, inasmuch as they go to show that albinism in Orchids is inherited in a similar manner to albinism in Sweet Peas and Ten-week Stocks, and in accordance with Mendel's law. An albino Orchid is distinguished from a coloured one by the absence of purple sap. For instance, the well-known Paphiopedilum (Cypripedium) insigne Sanderæ is an albino form from which the

purple ray of the type has disappeared. Recent experiments with Sweet Peas and Stocks, carried out by Mr. W. BATESON, F.R.S., Mr. R. C. PUNNETT, and Miss E. R. SAUNDERS, at Cambridge, have fully demonstrated that the appearance of sap colour depends on the simultaneous presence of two colour factors. If both of the colour factors are present the sap is coloured, but if either (or both) of the colour factors is absent, the sap is colourless. With regard to the cases of Paphiopedilum (Cypripedium) brought forward by Mr. CHAPMAN, for the sake of simplicity we will call the two colour factors C and P. The typical coloured forms of P. insigne, P. bellatulum, P. callosum, and P. Lawrenceanum will therefore be carrying both of the colour factors C and P. Their albinos will, on the other hand, be carrying either the C factor alone, or the P factor alone (or neither). The known facts of the breeding of albinos of these four species seem to be in accordance with the conception that P. insigne Sanderæ and P. bellatulum album are carrying the factor C alone; while P. callosum Sanderæ and P. Lawrenceanum Hyeanum are carrying the factor P alone (or vice versâ), as the following table, comprising all the results known to me, shows:—

TABLE A.

1. P. insigne Sanderæ (C) × P. insigne Sanderæ (C) gives albinos (C C).
2. P. callosum Sanderæ (P) × P. callosum Sanderæ (P) gives albinos (P P).
3. P. Lawrenceanum Hyeanum (P) × P. Lawrenceanum Hyeanum (P) gives albinos (P P).
4. P. Lawrenceanum Hyeanum (P) × P. callosum Sanderæ (P) gives albinos (P P).
5. P. callosum Sanderæ (P) × P. insigne Sanderæ (C) gives coloured hybrids (C P).
6. P. callosum Sanderæ (P) × P. bellatulum album (C) gives coloured hybrids (C P).
7. P. bellatulum album (C) × P. Lawrenceanum Hyeanum (P) gives coloured hybrids (C P).

The next table gives the remaining possible matings between the albinos concerned, together with the *expected* results:—

TABLE B.

1. P. bellatulum album (C) × P. bellatulum album (C) should give albinos (C C).
2. P. bellatulum album (C) × P. insigne Sanderæ (C) should give albinos (C C).
3. P. insigne Sanderæ (C) × P. Lawrenceanum Hyeanum (P) should give coloured hybrids (C P).

Future results will show how far the above conception, based on Mendel's laws, is correct. If Mr. CHAPMAN thinks well to self the coloured hybrids that he obtained from two albinos, he may expect to get, on the average, nine coloured forms to seven albinos.

Bi-generic hybrid Orchid.—Mr. R. A. ROLFE, A.L.S., drew attention to the bi-generic Orchid Epi-diacrum Colmanii shown by Sir JEREMIAH COLMAN, Bart., and raised between Diacrum bicornutum ♀ and Epidendrum ciliare ♂, and remarked that this new and interesting hybrid approached closely in habit, inflorescence, and form of flower to the pollen parent. He also commented upon the question of the nomenclature of bi- and poly-generic hybrids, saying that he considered it best to compound the name of the hybrid from the names of the parent species, and to avoid conventional names, unless they were so formed, as long as it is possible to do so.

Green-flowered Primula sinensis.—Mr. A. W. SUTTON showed a plant of Chinese Primula with green flowers, arising apparently from chlorosis of the corolla. The seed had been sown in 1904 and onwards, and had each year bred true, until this plant had appeared among the seedlings raised last year. Only once before had Mr. SUTTON seen a similar thing, and that was in 1902, when the same kind of sport occurred in another stock of double white P. sinensis, but in that case the flowers were not so well developed. The pollen of this plant appears perfect, and possibly seeds may be obtained hereof.

Colour sports in Boronia and Eria.—Mr. H. J. VEITCH showed a plant of the albino form of Boronia megastigma, a portion of one branch of which bore flowers of the normal colour, purplish brown, thus reverting to the type from which the sport arose.

Crocus with parts in fives.—From Mr. H. J. ELWES, F.R.S., came a Crocus flower having ten perianth segments in two whorls, five stamens alternate with the outer perianth pieces, and a five-branched style.

Curious Mushroom.—Mr. H. HARRIS, of Denne Park Gardens, Horsham, sent a Mushroom having a second complete but inverted Mushroom attached to the pileus.

"Canker" caused by Monilia.—Mr. DUNLOP, of Armaghmore, sent a branch of Apple Lord Derby with cracked bark, giving it the appearance of incipient canker. Inspection revealed the greyish sclerotia of Monilia fructigena in the cracks, and Mr. MASSEE said that this fungus, which is perennial in the tissues, forms sclerotia beneath the bark, causing the latter to be raised and to crack. Spores are formed on these sclerotia, and the disease spreads thence to the young leaves, shoots, flowers, and fruits.

Begonia rust, &c.—Mr. R. H. CURTIS sent leaves of Begonia Gloire de Lorraine with rusty spots and markings on the leaves due to the attack of the Begonia mite. This pest is difficult to eradicate, but constant vigilance and fumigation whenever necessary will usually keep it under. A good wash for dipping plants attacked by mites is made by kneading a handful of soft soap with a quantity (indefinite) of flowers of sulphur, and dissolving the whole in 1 and 1½ gallons of water; but even this, probably the most deadly wash for mites, and, at the same time, harmless so far as the plants are concerned, is not always efficient in killing the eggs of the mite.

Tuberous Solanums.—Mr. A. W. SUTTON read a paper on "Wild Types and Species of Tuber-bearing Solanums," illustrated by lantern slides.

COLONIAL EXHIBITION.

MARCH 5.—The tenth exhibition of Colonial produce, held at the R.H.S. Hall, Vincent Square, under the auspices of this society, was opened on the above date by Sir Somerset French, K.C.M.G., Agent-General for Cape Colony. The exhibition much resembled those that have preceded it, and as several collections of fruits had not arrived in time for staging at the opening ceremony, the hall was even more sparsely occupied than on former occasions.

The principal exhibits were from the South African Colonies, but Nova Scotia contributed a collection of Apples, for which a Gold Medal was awarded. This high award was also granted to Mrs. C. DU P. CHIAPPINI, for table fruit decoration and collection of fruit; T. J. POUPART, Esq., Covent Garden, for Grapes, Apples, Melons, and other fruits; and the ARMY AND NAVY AUXILIARY STORES, for a collection of Colonial fruits.

So far as fruit was concerned, the Grapes hardly excelled the samples received so cheaply from Spain, and were much inferior in quality and appearance to home glass-grown Grapes. Melons lacked the attractive appearance seen in well-grown British fruits, but the round, ribbed green Murthe Melons from the Cape were of a delicious flavour, although some three weeks or more had elapsed since they were cut. The large yellow Peaches seen were not tempting; but some white Peaches of a medium size, and Nectarines, though small, were much more attractive. The Japanese Kelsey Plum was freely shown on all the Cape stands, many of the fruits being very large. It is a clingstone variety. Pears were plentifully shown, especially Williams' Bon Chrétien, Duchess d'Angoulême, and Beurré Hardy. These fruits had been carefully packed in boxes, and came to hand in a condition of perfection. The best Apples came from Nova Scotia and Ontario. Whether in tubs or boxes they were generally rich-coloured and handsome.

BRITISH GARDENERS' ASSOCIATION.

METROPOLITAN MEETING.

MARCH 7.—A meeting was held on this date at Carr's Restaurant, Strand. It was convened especially in the interests of gardeners employed in the London public parks, but was open to all engaged in horticulture, and a representative attendance was secured. Mr George Gordon, V.M.H., occupied the chair, and had for his supporters Messrs. E. F. Hawes (treasurer), John Weathers (secretary), T. Lewis, and R. L. Castle (members of the Executive Council).

The chairman opened the proceedings shortly after 7 p.m. with a brief introductory speech, in which he reviewed the necessity for, and the advantages of, a strong association of gardeners. He commented upon the isolation of gardeners, their inadequate pay, and the many difficulties under which they laboured, that individually they were almost powerless to remedy. In combination on co-operative principles, it might be possible to improve the condition of gardeners, and at the same time benefit the employers. The progress must necessarily be somewhat slow at first, but it was better to advance gradually and surely than to rush ahead heedlessly and court disaster. The chairman regretted to hear some say they would wait to see what the B.G.A. did before joining. This was an exceedingly selfish idea; it simply means that they would take advantage later of the work and self-denying efforts of those who were now strenuously endeavouring to establish the association on a substantial basis.

Mr. J. Weathers dealt with the various attempts which had been made to form gardeners' societies, stated the mistakes which had led to failure, and described the origin of the British Gardeners' Association. One of the essential objects was to distinguish the true gardener from those who claimed the title without justification, of whom unfortunately there were far too many. When horticulturists speak of a gardener they know exactly what they mean, but the general public use the name in a very vague manner, and this has resulted in a serious lowering of the status and pay of experienced men. The B.G.A. requires full information respecting a man's experience and ability before admitting him to the ranks, and the Certificate of Membership is therefore a proof that he is not an impostor as regards the work he undertakes to perform. This should not only be beneficial to the man, but also a safeguard to the employer. Mr. Weathers referred to other evils, such as excessively long hours, unpaid overtime, insanitary and incommodious bothies, which demanded attention, and upon which the B.G.A., it was hoped, might eventually be able to effect improvements. Over 300 members have joined the association in the past year, but though the total now exceeds 1,200, many more should join, as the annual subscription of 2s. 6d. is so low that it must be within the power of all.

The advantage to gardeners of having an official body behind them in the case of any dispute about the payment of wages, keeping the terms of agreements, verbal or otherwise, as to notice to quit, &c., were described at some length, and several instances were given where the B.G.A. had already rendered substantial help in this way, without having to resort to legal remedies. All such matters were enquired into very closely by the Executive Council, and when a legitimate grievance was found to exist, the rules authorise the officials to deal with it as may be deemed advisable in the interests of members.

The *Journal* of the B.G.A., which has been issued quarterly, and will now be published monthly, is also a means of helping gardeners. Reference was made to the Cardiff District Council, who had adopted the B.G.A. Certificate of Membership as a sufficient indication that the man was a qualified gardener. It was believed that both in the London County Council parks and the Royal parks and gardens, substantial improvements might be effected if the authorities would give attention to this subject, and endeavour to make a satisfactory distinction between the experienced and inexperienced men.

Mr. E. F. Hawes followed with some pertinent remarks upon the admission of members, stating that all the B.G.A. required was proof of experience, which need not have been gained in large gardens only. It often happened that highly-qualified men had been trained in small places. He also referred to the examinations in horticulture which, as at present carried out, did not fulfil the objects which the B.G.A. had in view. In reply to a question that was asked Mr. Hawes further stated a sub-committee of the B.G.A. Executive Council had been appointed to consider the subject and submit a scheme and report at the next annual meeting.

Mr. T. Lewis gave some interesting reminiscences about bothies of former years, and he described one that was most seriously defective 30 years ago, and is very little better now, notwithstanding the sanitary inspectors and local boards.

In response to an invitation from the chairman, questions were asked by those present, which were fully dealt with by the secretary, and, after a prolonged discussion, it was decided that a metropolitan branch of the B.G.A. be

formed to meet periodically on the same lines as the other branches of the association. It was also decided that a meeting should be held for the purpose of organising the branch, on March 21 at the same place, i.e., Carr's Restaurant.

RICHMOND (SURREY) BRANCH.

February 25.—A public meeting was held in Richmond, Surrey, on the above date. Mr. E. F. Hawes gave an interesting address, and especially emphasised the need for co-operation amongst professional gardeners. He was supported by Mr. Dallimore, who dwelt on the necessity for drawing a line of distinction between the gardener and the garden labourer, and by Mr. J. Weathers, who gave much useful information relating to the B.G.A., and said that the executive council was always ready to support any of its members in litigation, provided they could state a good case. *W. B. L., Branch Sec.*

HORTICULTURAL CLUB.

March 3.—The usual monthly meeting took place on the above date, Mr. Harry J. Veitch presiding. Mr. Chas. Pearson, who had promised to give a lecture on Birds Eggs, was unable to be present. Mr. R. H. Read very kindly filled the gap at short notice, and gave a description of an ornithological excursion in Southern Spain, illustrated by numerous lantern slides. The lecturer prefaced his exhibition of views and nests *in situ* by a graphic account of his trip in the spring of 1906, the object of which was the study of the birds of that country. On the way thither he passed through Bordeaux, where he saw immense forests of Pines, largely devoted to the production of turpentine, every tree being scored longitudinally and provided with little collecting cups, the raw product being worked up by Terebine factories on the spot. Passing onwards, the various phases of spring vegetation were touched upon, and also, of course, the numerous species of birds, many of which were obviously migrating in enormous numbers on their way hither and elsewhere, willow warblers, blackcaps, nightingales, &c., figuring among them. Arrived in the Jerez or sherry-producing district of Spain—the word sherry being really an approximation to the Spanish name, while the old word sack was a corruption of seco or dry, sherry sack meaning dry sherry—the lecturer made his way to the curiously constituted bird paradise known as the Marismas, a vast area of flat land covered during the winter and spring by about 2 feet of water, which dries up in the summer, leaving large expanses of sun-dried mud, varied by stretches of sand and shingle. Birds of innumerable kinds abounded here—herons, stilts, terns and other waterfowl, and egrets, kites and other birds of prey. A curious arboreal feature in this district was that owing to the scarcity of fuel, the pine trees were all denuded of their lower branches and were consequently reduced to somewhat mop-like forms. In some places drifting sand invaded both trees and smaller vegetation, and some of the slides showed curious effects arising from it. Among the most interesting slides were those showing various nests, such as those of herons and eagles, &c., which were built high up in lofty trees, while another series depicted ground nests, in many cases hardly worthy of the name, the eggs being laid in all but invisible groups among rough stones and shingle, and by their mottled coloration, almost defying the eye to detect them. The nest and eggs of many aquatic birds were also shown cosily planted amid the reeds and rushes, which in many cases necessitated standing knee-deep in water in order to obtain the photograph.

SCOTTISH HORTICULTURAL.

March 3.—There was a crowded attendance in the Goold Hall, Edinburgh, on the above date, of members of the Scottish Horticultural Association, when Mr. Whytock, gardener to the Duke of Buccleuch at Dalkeith Palace, the president of the association, delivered his inaugural address. His subject was "The Horticultural Outlook." Horticulture, he said, as they had to deal with it at the present time, might be divided into four large important and distinct sections, namely, nurserymen and seedsmen, market gardeners, city and town gardeners, and the private gentleman's gardener. Scottish gardeners were found the world over, and from that chief centre in Scotland they might safely assert a large proportion of these men had gone forth. The highest excellence in the large private gardens in Britain was undoubtedly attained between the years 1850 and 1870, during which time it was said that Drumlanrig was the finest garden in Europe. Nemophilla, Verbenas of various colours, Stocks, Tom Thumb Pelargoniums, and Calceolarias which were used at Drummond Castle, Bothwell Castle, and Tulliallan Castle gardens about 1860 would be despised now. Mr. Whytock compared the improved lot of the young gardener at the present time with his lot in past years, when the journeyman's wage was 11s. weekly. By 1870, it was pointed out, the period of depression in trade had passed away. Horticulture began to be thoroughly democratised, and the market garden, public gardens and pleasure grounds came into prominence.

There was probably no city in the kingdom that had been more favoured with winter gardens in their parks and gardens than Glasgow. As few of these glass houses were in existence when the present superintendent, Mr. Whitton, was appointed, it would seem that that very able gardener by his initiative induced liberal-minded merchant princes in Glasgow to give large sums for their construction, and also to make gifts of beautiful pleasure grounds. In spite of the agitation which had been carried on since the year 1870, Edinburgh had not yet got anything of the kind. After a reference to the excellent entertainment which the Society's shows provided, the President said that during the past 30 years in the enormous increase in industrial and mercantile energy, and the corresponding increase in wealth, horticulture had been equally energetic. The people had now splendid pleasure grounds and beautiful gardens of their own to walk in and enjoy, and they had brought to their own doors incomparably better fruit, flowers, and vegetables than could be got 30 years ago, and at such low prices that it was surprising they could be so cheaply produced. There was admittedly some depression at present, but they were justified in thinking the depression would soon pass. Commercial horticulture had a great future, and probably gardeners would find that they would have more specialists in their ranks. The art of gardening would flourish more than it had yet done, and there would be plenty of room and good wages for competent men.

An exhibit of Lilacs and Indian Azaleas, grown by Mr. Reid, was shown during the evening, which bore testimony to the efficacy of electric light in bringing the bloom rapidly to perfection. All the plants had been grown side by side, but two of the Lilacs and two of the Azaleas had been continuously exposed to electric light for from 10 to 14 nights, and were in beautiful flower, while in the plants shaded from the light the flowers were mostly in the bud stage.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

February 20.—*Committee present:* Messrs. E. Ashworth, R. Ashworth, Warburton, Cowan, Sander, Keeling, Shill, Ashton, Cypher, Parker, P. Smith, and Weathers (hon. sec.).

There were fewer Cypripediums shown on this occasion, owing to the lateness of the season for these Orchids, but there was a first-class show of other subjects.

J. Macartney, Esq., Bolton (gr. Mr. Holmes), exhibited Lælias and Cattleyas in competition for prizes offered by Messrs. Hugh Low & Co., and was awarded a Bronze Medal, while the same exhibitor gained a Silver Medal in the "Thomson" Competition.

A. Warburton, Esq., Haslingden, gained Silver Medals in the "Sander" Competition and in the "Thompson" Competition. Amongst the plants shown by Mr. Warburton were Cypripedium × Empress of Russia, which received an Award of Merit, and Odontoglossum sceptrum var. Masoreelianum, an albino form, and to this a First Class Certificate was granted.

H. J. Bromilow, Esq., Rainhill, Liverpool (gr. Mr. Morgan), staged a group of Cypripediums, many of which were well-known species and hybrids. Cypripedium Fairrieanum var Othello, a handsome dark variety, received an Award of Merit. A Silver Medal was awarded to the group.

R. Farrer, Esq., Carnforth, was awarded a First Class Certificate for Odontoglossum × ardentissimum Ingleborough var.; the flower is distinct and beautiful, being not unlike O. × a. var. Robsoniæ.

S. Gratrix, Esq., Whalley Grange (gr. Mr. Shill), gained First Class Certificates for Cypripedium × aureum var. Lækenense, and C. × Mrs. J. E. Shill (Actæus × Leeanum), also an Award of Merit for Dendrobium Thwaitesiæ.

Messrs. Charlesworth & Co., Bradford, staged a charming group of plants, to which a Silver Medal was awarded. In the exhibit was Sophro-Lælia Feliciæ, a richly-coloured hybrid between Sophronitis grandiflora and Lælia Dayana, and to this plant an Award of Merit was granted. Cymbidium Woodhamsianum, shown by the same exhibitor, received a similar award.

Z. A. Ward, Esq., Northenden (gr. Mr. Weatherby), exhibited Odontoglossums, including both species and hybrids. A Silver Medal was awarded the group, and the following four plants were given Awards of Merit:—O. × Warnhamense, O. × Harryano-triumphans Ward's var., O. × Ossulstonii Ward's var., and O. Pescatorei var. Louise.

R. Ashworth, Esq., Newchurch (gr. Mr. Fletcher), staged a group, which included Odontoglossum × Loochristiense var. Mikado. (Bronze Medal.)

Messrs. Cypher & Sons, Cheltenham, were awarded a Silver Medal for a choice display, consisting of good Cypripediums, Dendrobiums, &c. Bronze Medals were awarded to Messrs. Heath & Sons, Cheltenham; Moore & Co., Rawdon, near Leeds; J. E. Sadler, Newbury, Berks; Keeling & Sons, and W. Shackleton, Bradford, for groups of Orchids. *P. W.*

COMMONS AND FOOTPATHS PRESERVATION.

At the recent monthly meeting of the Commons and Footpaths Preservation Society, it was reported by the chairman (Lord Eversley) that the society had received from upwards of 200 members of all parties of the House of Commons promises to support its Rights of Way Bill, introduced by Mr. R. Winfrey, M.P., the second reading of which had been set down for May 29. The Bill provides that proof of the use of a way for twenty years without interruption or permission in the case of freehold land, or forty years in other cases, shall be sufficient to enable a court of law to assume that dedication has taken place. The solicitor stated that in consequence of the society's opposition, the Liverpool Corporation had withdrawn from its General Powers Bill a clause which would have enabled the corporation to close public footpaths extending over its Rivington Waterworks Catchment area without complying with the safeguards imposed in the public interest by the Highway Acts. The threatened sale of the site and grounds of the Duke of York's School at Chelsea was also considered, and it was unanimously resolved, upon the motion of Sir William Vincent, seconded by Sir Robert Hunter: "That in the opinion of the society it is eminently desirable that if the removal of the Duke of York's School from Chelsea to Dover be completed, a portion of the present site should be reserved for open space purposes, especially as it is understood that the cost of the removal would be more than met by the sale of only two-thirds of the site at Chelsea, and that such action as may be necessary be taken on behalf of the society in Parliament or elsewhere to attain this end." It was reported that the society's scheme for the regulation of Towyn Trewan Common, Anglesey, a tract of 1,300 acres of open land, was proceeding satisfactorily. Up to the present £1,391 had been received or guaranteed towards the £1,800 needed to acquire Ludshott Common and the wooded slope facing Waggoners' Wells, Bramshott, 560 acres in extent and one of the most beautiful commons in the Hindhead district. It was stated that only three weeks remained for raising the residue of the purchase money—£407—and it was decided to issue an appeal for this sum.

ANSWERS TO CORRESPONDENTS.

CHRYSANTHEMUMS TO FLOWER IN JANUARY: *H. Reynolds.* It is not an easy matter to cultivate the latest flowering Chrysanthemums. We have before us a letter from one of the leading growers, who states that where one succeeds ten may fail, and this has been repeatedly proved. This correspondent sent splendid blooms of one variety to market in January, but we learn from another market grower that with him the same variety has entirely failed. Cultivators have to reckon with the weather, and last autumn was particularly unfavourable for the late varieties. The plants may be started early, but must be kept growing freely and stopped from time to time until about August. Only the strong, free-growing shoots should be left to mature their flowers; the most successful cultivators get from eight to twelve blooms on each plant. In some varieties fifteen blooms of good quality may be grown on each plant. It is essential to provide sufficient pot room and manure to keep the growth vigorous and free up to a certain point, but it being necessary to secure flower-buds, if growth appears too vigorous, the manure must be withheld until the buds appear. The variety Mrs J. Thompson has held out up to the end of January, Allman's Yellow nearly as late, but Nagoya does not hold out quite so long. Madame R. Oberthur has been very good up to last week. Madame Therese Panckouke is one of the very best. T. Canning is a good flower, but few growers succeed with it. The latest crimson variety noted in the market is W. J. Crossley, but this requires careful treatment. Growers who fail with this variety succeed better with Matthew Hodgson. Only those cultivators who have the advantage of sunlight during the autumn can grow the latest flowers. In districts where fogs prevail, it is next to impossible to flower Chrysanthemums so late in the season.

CINERARIA SEEDLING: *H. G. L.* There are varieties already in commerce similar to the one you send us, and which has no particular merit.

CORRECTION.—In column 3, p. 146, of our last issue, for Rhamnus catharticus read Hippophaë rhamnoides.

DAMAGED FOLIAGE: *A. B.* By the appearance of the various specimens received, it is evident that there is a very unsuitable atmosphere, at times at least, in the house in which the plants are cultivated. If the interior of the house has been recently painted, or if the hot-water pipes have been painted with unsuitable colouring material, or even if the house has been insufficiently ventilated, the plants might be expected to suffer in this manner. Such damage has occasionally arisen from fumes from the stokehole getting in. These are matters which you must investigate yourself. Meanwhile, do not employ an excessive degree of fire heat; ventilate carefully, leaving the ventilator open just a little throughout the night.—*Constant Reader.* See answer to *A. B.* Condensed moisture, by reason of the temperature falling suddenly, may have contributed to the injury.

EMPLOYMENT IN THE LONDON PARKS: *R. E.* The public parks of London are under the management of two authorities—the London County Council and His Majesty's Board of Works. The latter authority has control over the Royal parks, including Hyde, Regent's, St. James', Greenwich, &c. For admission to these you should apply to the respective superintendents. For admission to the staff of the London County Council's parks apply to Col. Sexby, 11, Regent Street, London, W. The wages of the gardeners employed in the London parks are highest under the London County Council.

EVERGREEN OAK: *T. H. G.* The spots on the leaves are due to a fungus of the genus Ascochyta. Species of this group cause leaf spots on many plants. Burn all fallen leaves as soon as possible. If the Oak is but a bush, hand-picking of the leaves and burning them will prevent the disease effectually. Spraying will be of no use, as the fruiting portion of the fungus lies well protected underneath the felty layer of stellate hairs on the lower surface of the leaves. This special pest is called Ascochyta quercus ilicis (Guss.).

GARDENING IN AMERICA: *J. S.* A list of American gardening journals with their addresses was published in our issue for February 15 last. In respect to wages paid to gardeners in America, they vary as in this country, but they are generally higher than in England, against which must be set the increased cost of living in that country. As an example of the knowledge required and the wages paid, it may be remarked that in a recent issue of the *Florists' Exchange*, published at Duane Street, New York, appeared an advertisement for "a first-class Rose, Carnation, Chrysanthemum, Violet, and general stock grower," the remuneration offered being 15 dollars per week, a sum equal to £3 2s. 6d.

HARDY CYCLAMEN: *B. L.* In regard to the length of time these species require to become established, much depends upon the nature of the corms. If they are imported (collected) corms, one year is sufficient for *C. neapolitanum*, but very old corms of this species may never regain strength after transplantation. If the site is somewhat dry, and there is ample lime in the soil, *C. Coum* will become perfectly established in the second year, but old corms may not break into growth for several years afterwards. *C. europæum* is not a satisfactory garden plant at any time, and, although many thousands of corms are annually collected and sent to this country, but few survivors remain in a thriving condition in the third year. Home-raised seedlings are not much better than imported corms, and many die before flowering. The best way of establishing Cyclamen is to pot the corms, start them in a frame, and plunge the pots outside as soon as growth is in evidence. Allow the corms to remain until they flower and seed. When in seed, plant them out in their permanent home. These plants bury their own seeds, and thereby form colonies around the original clumps.

HIPPEASTRUMS: *H. S.* The material received is not sufficient for proper examination. The portion of flower-spike mentioned in your letter was not enclosed!

HYACINTHS: *W. H.* There are traces of roots on your Hyacinths, but they have been destroyed by a small mite, a species of Rhizoglyphus, probably R. dujardinii, which is known to occur on roots of Hyacinths. It would be better to place the bulbs on a layer of sand and not directly on the soil, as is done in your case. The sand encourages the growth of roots, and afterwards when penetrating into the soil they are better able to resist an attack of Rhizoglyphus.

MANURES FOR VINES AND PEACHES: *Anxious.* Nitrate of soda and sulphate of ammonia supply immediately available nitrogenous plant-food, while sulphate of potash and superphosphate supply the mineral elements only. Bone meal supplies both phosphates and a little slowly-acting nitrogen. For vines mix together one part sulphate ammonia, two parts sulphate potash, and three parts superphosphate, and apply at the rate of ½ oz. per square yard once a week from the time the laterals are 1 foot in length until the berries begin to colour. The mixture may be sown on the surface and watered in with a weak dilution of drainings from the cow-shed. Each watering after the Grapes are set should be sufficient to pass through the soil and drainage. When vines are in a strong, healthy condition and heavily cropped, and it is doubted whether the berries will finish perfectly, a good external watering of cowshed drainings through a liberal mulch of rotten manure very often turns the scale in favour of the Grapes. Immediately after the Grapes are cut, both the external and internal borders should receive an application of bone meal at the rate of 1½ ozs. per square yard, to be lightly forked in. The vines will also derive great benefit from another mulching of short manure or decaying leaves to keep the surface moist during the autumn months. For Peaches, lightly fork into the border during winter or very early in spring a mixture composed of two parts bone meal, one part sulphate of potash, and three parts superphosphate, to be given at the rate of 4 ozs. per square yard. When the Peaches are set, and the trees are in free growth, a liberal application of diluted cow-shed drainings should be given every evening, as the roots then have the benefit of a cool, refreshing bath, extending throughout the night. At this stage of growth, and more especially if the weather is warm, it is not easy to water a properly-drained tree too liberally.

MANURES FOR YOUNG VINES: *Constant Reader.* The success of a vine border will depend greatly upon the class of soil at your disposal. The soil should consist of two-thirds good friable, turfy loam, the fibre of which will not too readily decay, and which will at all times admit of a free passage of water, which the vine requires copiously. But lest the soil should in course of time become close and inert, the remaining third should consist of lime-rubble, powdered charcoal, and burnt earth, with 3 lbs. bone meal, ½ lb. sulphate of potash, and 2 lbs. superphosphate to each 2 cwt. of soil. Animal manures need not be used for young vines, but a liberal application of weak liquid manure from horse stables or cow-sheds may be given in subsequent years at short intervals from the time the leaves unfold until the fruit is nearly ripe.

NAMES OF FRUITS: *J. C. P.* Apple Rymer.—*W. B. B.* Dumelow's Seedling, syn. Wellington.

NAMES OF PLANTS: *R. F.* 1, Pittosporum tenuifolium; 2, Danaë Laurus (Alexandrian Laurel); 3, Podocarpus chilina; 4, apparently Nerium Oleander; but the leaves are usually in whorls of three.—*T. N.* 1, Phillyrea media buxifolia; 2, Osmanthus rotundifolius.—*W. W. H.* Sparmannia africana, a South African plant. It thrives admirably in the dwelling-house, and may often be seen in bloom in cottagers' windows.—*T. I. T.* 1, Dendrobium Kingianum; 2, Iria acervata; 3, Miltonia spectabilis; 4, Ada aurantiaca.—*J. J.* Epidendrum ciliare.—*V. H.* 1, Selaginella Wildenovii; 2, Nephrolepis exaltata; 3, Pteris longifolia; 4, Polystichum angulare; 5, Adiantum cuneatum; 6, Adiantum caudatum.—*G. C.* Sequoia sempervirens.

QUICK HEDGE: *V. S.* The shoots are suffering from a species of Cytospora, which is the forerunner of a more highly-developed fungus of the genus Valsa. All the Rosaceous plants are liable to its attacks. If you cut the plants back beyond the diseased spots, it may save the rest.

SPECIALISING: *F. B.* If you wish to become a specialist in some branch of horticulture, you cannot do better than continue your studies and duties among Orchids, of which plants you have some knowledge already. To become an expert in any one branch of gardening needs not only an aptitude for that particular section of gardening, but also a love of the subject. If you have the artistic taste and instinct for landscape work, that branch of gardening is to be recommended. You should endeavour to obtain admission to some large garden, such as the Royal Botanic Garden at Kew, where you could gain an insight into most of the branches of horticulture, and thus choose for yourself.

VIOLETS: *E. G. S.* The Violets are attacked by the fungus Ascochyta, often referred to in these pages, and for which there appears to be no remedy. Procure a fresh stock of plants.

VIOLETS FOR CANCER: *J. W.* We receive occasional letters from correspondents asking whether the application of Violet leaves can be used with any expectation of cure in cases of cancer. It cannot be too strongly stated that in properly diagnosed cases of this disease such experiments are worse than useless. They involve waste of invaluable time, and defer the surgical aid which, so far as our knowledge goes, affords the only chance of relief that can be hoped for. Of course there are some cases known, but they are unfortunately rare, in which the growth has become apparently naturally arrested in its advance, but the advice of a properly qualified medical man should be sought in every instance as early as possible, for therein lies the patient's best—we had almost said only—chance.

SEEDS AND SEEDLINGS.

NOW that the time for general seed-sowing is at hand, gardeners should bear in mind that upon the quality of the seeds will depend mainly the character of the plants which will result from their sowing. The first essential of a seed is that it shall be of such a nature as to practically ensure that the resulting plant will reproduce the parental character undeteriorated. It is because a large number of plants under cultivation are of such a mixed character, and their seeds consequently cannot be relied upon to reproduce the parental form, that it becomes necessary to propagate them by cuttings, budding, or division.

For the amateur to collect seed from plants of this description is to court what florists would describe as failure, though it occasionally happens that amongst the varied offspring a valuable novelty appears, by reason of the capacity for variation which is possessed more or less by all plants. At the same time, the florist has found that if skilled and careful selection is carried out, seed can be obtained which will reproduce the parental type truly, with little or no tendency to variation. In such cases the reputation of the seed-grower is an important factor to the purchaser, forming as it does some guarantee for the quality of the crop.

Seed also varies in respect to its state of development. If a packet of seed be examined, it matters little what seed it may be, it will be found that the grains vary in size, and as greater size usually indicates a larger store of nourishment for the incipient seedling, it is obviously worth while to sow the larger ones in preference to the smaller. This is especially the case where seeds are of sufficient size to be sown separately.

It is very important that seeds should be sown thinly in order that the seedlings may be given a fair start. No matter how good the seed may be, if on germination a crowd of seedlings is produced, the tiny plants will suffer a weakening effect that can scarcely be overcome by subsequent thinning out, a process that is often indulged in to a wasteful degree. It is not intended, however, to imply that thinning out should always be unnecessary, for in practice it is sometimes desirable, even when the seed has been sown with judgment. But the amateur is too often induced to err in the other direction, i.e., of sowing too thickly, by the fact that the packet of seed supplied to him would often suffice to fill his space entirely if every seed were given an opportunity to grow, and hence he sows within a small area which a good, healthy plant could entirely fill to advantage enough seed to produce scores. Nature commonly avoids this. Take, for instance, a ripe Poppy capsule raised aloft on its slender stalk. Round its upper edge is to be seen a series of perforations almost like those in a pepper castor, and as the wind blows the fruit sways backwards and forwards, and slowly scatters its contents broadcast over a considerable area. All the Composites send their seeds far and wide; the Balsam tribe and the Woodsorrel are types which shoot their seeds yards away from the parent. The result, as we see by chance-sown plants in our gardens, is such a measure of robustness which is rarely seen in plants raised from seeds sown by the packet in a limited area.

The seed sower should, therefore, first obtain seed of really good plants from a reliable source, and finally give them sufficient room to develop from the very outset of their existence by remembering nature's lesson in regard to broadcast distribution. *C. T. Druery, V.M.H.*

FRUIT IN NEW ZEALAND.

HAVING regard to the delightful climate of this colony, the traveller naturally expects to meet with an abundance of good fruit there. Arriving in Auckland at about the middle of December, I found Strawberries were plentiful everywhere. They are grown in almost every garden, and at Christmastide the berries are much in request for picnic parties and numerous other social functions. The varieties mostly grown for market purposes are Marguerite and Trollop's Victoria, but in point of flavour I found the old Carolina Superba the best of those I tasted.

In the province of Auckland nearly all fruits indigenous to temperate or semi-tropical climates thrive, consequently the cultivator in that district has a great range of fruits to select from. Although Apple trees grow well and bear freely, it is disappointing to find the trees are infested with the American blight or woolly aphis. This pest attacks root and branch alike, and spreads with great rapidity, so much so that the whole of the trees in many orchards have had to be grubbed up and burned. Government experts and other persons are doing their best to combat the insect, but so far they have only met with moderate success. The variety Cox's Orange Pippin is especially susceptible to its attack. Northern Spy is said to be immune from the blight, but this is not entirely true, for at Henderson a tree of that variety was seen to be badly infested. Pear trees are largely grown, and generally bear abundantly. Many of the varieties popular in Britain are favourites in the colony, including Williams' Bon Chrétien, Beurré d'Amanlis, Beurré Hardy, Doyenné du Comice, Flemish Beauty, Jargonelle, Louise Bonne of Jersey, and Winter Nelis. Cherries are not largely grown in the Auckland district, but I was informed that I should see more of them as I proceeded southwards. Peaches, trained as standard trees, are to be seen in almost every garden, but the European varieties are not often planted on account of their delicate constitution and being so subject to the dreaded silver-leaf disease. Seedlings raised from the American yellow-fleshed kinds seem to be the most in favour. The varieties Crosby and Elberta are largely grown for marketing purposes. "Kia Ora," Maori-land, and Osprey Improved are said to be handsome, valuable acquisitions. As the fruits of these kinds were not ripe at the time of my visit, I cannot pronounce an opinion as to their quality. An orchard of standard Peach trees with Gooseberry bushes growing under them, although common in New Zealand, is one of the things not seen in Britain. Nectarines are not so largely grown in the colony as Peaches; the yellow-fleshed kinds of this fruit are also preferred. The best varieties met with are Byron (Rivers'), Darwin (Rivers'), Ansenne, Twyford Surprise, and Gold Mine; the last named is a new variety of great promise, and some of its largest fruits are said to measure 9¾ inches in circumference. The skin is of a beautiful bright bronzy-red, the flesh being of a pinky-cream colour, melting, and delicious in flavour. This novelty should prove an acquisition in the mother country.

Apricot trees grow well and bear abundantly. They are trained either as bushes or short standards. The majority are either American or local varieties, but also I saw trees of Moorpark, Hemskerk, and Large Early, varieties well known in British gardens. The European varieties of Plums are not so extensively known in Auckland as in Otago, where the climate is cooler. The trees, however, suffer so much from silver-leaf disease that they are passing out of cultivation, Gages being the only kinds that do well. The Japanese Plums and their hybrids furnish valuable substitutes; these grow freely and are not very susceptible to insect pests and fungoid diseases. They yield prodigious crops of delightful fruit. Mr. McIndoe, at Otahuhu, grows about a dozen varieties, the best and most popular sort being Burbank, which is a very delicious fruit. The fruits of another variety named Satsuma

are largely used for preserving purposes; excellent jam is made from its bright red flesh, the conserve being highly esteemed by the colonists. The varieties Wickson, Doris, Kelsey, Kikko, and Gold are what the market growers term good "shippers." Trees of the last-named variety when laden with ripe fruit are conspicuous objects.

The Persimmon, in common with all other Japanese fruits, is admirably adapted to the climate of the north island. Its fruits vary in colour from bright orange-red to light vermilion, and they are highly esteemed by the New Zealanders. Fig trees are met with in many gardens, Brown Turkey, Brunswick, and Angelique being the kinds most frequently cultivated. Melons are plentifully grown, the favourite kind being the Spanish Water Melon. The Loquat apparently succeeds well, a local variety named Thane's Prize being considered the best. Oranges, Limes, and Lemons, especially Lemons, are other fruits that are extensively grown in the colony.

Lemons are inferior to those from Sicily and other parts of Italy. The Lisbon and Eureka are varieties in demand. The Limes known as Tahitian and West Indian are considered the best. The Purple Guava is grown in many gardens forming a bush that produces fruits abundantly. Guava jelly is a much esteemed luxury. A popular fruit is that of the Maurandia (Passiflora edulis). It is usually planted in stony or rocky places or against walls, dead trees, &c., where its rambling growths have a free run, and in such a position enormous crops of the purple fruits are produced. So great is the demand for the berries that they are to be seen in almost every fruit shop window. One cultivator of this fruit informed me that although his crop would be nearly two tons, he would have no difficulty in disposing of them at remunerative prices. As grown in New Zealand its flesh and flavour somewhat resemble those of a good yellow Gooseberry The Cape Gooseberry is cultivated extensively for market purposes, and the fruits meet with a ready sale. Occasionally I saw plants of the Loganberry, American Blackberries, Medlar, Prickly Pear, Pomegranate, and the Tree Tomato, the last-mentioned as bushes quite 6 feet in height and as much in diameter, bearing numerous clusters of fruits. The berries were not matured at the time of my visit, but they are very highly esteemed by the inhabitants. Raspberries and Currants are not much grown in the colony, indeed the Black Currant cannot be grown successfully in New Zealand. Diseases and insect pests infest Apple and stone fruits very largely, and this, I think, is principally due to the short mild winters of the north island. The trees have but a short resting season, and insects breed all the year round. *J. McIntosh, V.M.H.*

ORCHID NOTES AND GLEANINGS.

ODONTOGLOSSUM CRISPUM ROTUNDUM.

THIS magnificent variety, which has again bloomed with J. Gurney Fowler, Esq., Glebelands, South Woodford, takes a prominent place in the front rank of the very best forms of blotched O. crispum, and when it attains sufficient strength to show itself at its best may be adjudged to be one of the finest which has yet appeared. In the matter of fine shape, breadth of both sepals and petals (features which are wanting in a large proportion of the otherwise good spotted O. crispum), it resembles the fine O. c. Cooksoniæ. The reverse of the sepals and petals is bright violet-purple, with a white margin. The sepals have clusters of reddish-purple blotches surrounded by smaller rose-purple ones. The fringed petals have large irregular blotches of a deep violet-purple tint, around which is an irregular band of rose-purple spots of varying size. The lip is of good size, white, with chestnut-brown blotches, and a yellow crest. It is one of Mr. John Carder's collecting, and first sent forth a flower with Mr. Gurney Wilson, Glenthorne, Haywards Heath, who named it rotundum, because of the circular form of the flower and the broadly ovate sepals and petals.

PIPTANTHUS NEPALENSIS.

WHILST there exists no lack of climbing plants capable of filling almost every garden requirement, there is always room for a good flowering evergreen whose foliage is excellent at all times and whose flowers are very attractive throughout summer, especially if the plant be one that can grow and thrive in normally poor soils provided the situation is warm, sunny and sheltered. Piptanthus nepalensis, the climbing Laburnum, more familiar, perhaps, to gardeners as Thermopsis laburnifolia, fulfils these conditions in no small degree, and wherever it is grown it is valued for its distinctive features. Although described as tender, save in sheltered situations, I have seen and admired many plants thriving under conditions which Ivy could barely endure, and when I note flowering specimens of considerable age in the East of Fife, in Forfarshire, in Cumberland, and in several Midland gardens, it becomes evident that its hardiness is considerable. The crux of the matter lies in the type of plant acquired. In common with most leguminous plants, Piptanthus makes simple roots 3 feet in length, whose first impulse is to descend as deeply as they can go; it then develops stems 3 feet long or more the first season, and reaches a height of 10 feet in the third year. Such a plant would thrive indefinitely; it has possession of the site and speedily covers the wall space allotted to it. What happens to the nursery-reared specimen is this. It is invariably reared from seeds, and when a foot high its roots are trimmed and the plant potted; its year's growth may exceed a foot. Soon, however, it finds the pot too restrictive, and shows

FIG. 75.—PIPTANTHUS NEPALENSIS, FLOWERS YELLOW.
(From a sketch by Mr. Worthington Smith.)

CATTLEYA TRIANÆ J. GURNEY FOWLER.

MANY thousands of Cattleya Trianæ have been imported from widely-separated localities in Colombia, and while no Cattleya displays so great variation in the form and colour of the flowers, it is very rare to find one so far in advance of others of its class as this beautiful variety, which bloomed out of an importation by Messrs. Sander last year, and is again flowering with J. Gurney Fowler, Esq. The flower is a perfect model of floral perfection, the broad sepals and the almost orbicular crimped petals being of a delicate blush pink. The broad crimped labellum is bright mauve-crimson, with a narrow lavender-coloured margin, the disc being yellow.

signs of debility owing to drought, lack of food, or other circumstances, and from this debilitated condition it never recovers. One can recommend with every confidence that two or three seeds of Piptanthus should be planted where the plant is to grow. They germinate quickly, and will outstrip the pot specimen in the first six months of their life. At midsummer, choose the strongest seedling and pull out the others. The youngster will require no "stopping." Its unripened tip will succumb to frosts, and in the following spring it will make lateral growths, each terminated by a raceme of yellow flowers that in shape closely resembles a bunch of Grapes, the individual flowers bearing a close resemblance to those of our native Gorse in colour, size, and shape. The foliage is also particularly attractive. The leaves are trifoliate, with lobes that are much broader than those of Laburnum, and are nearly as large as those of well-grown Broad Beans and exactly of similar shape. They are very glabrous, and are of that deep green colour which is characteristic of Ceanothus divaricatus when in health. The tallest plant I have seen was 15 feet high, but this had reached the top of the wall four years ago and had been stopped annually, the outgrowing shoots sharing the same fate. Flowers are never produced in excess, but in just that measure one can appreciate. *G. B. Mallett.*

FOREIGN CORRESPONDENCE.

PLANTS OF THE BIBLE.

THE kindly criticism of the *Plants of the Bible*, by the Rev. George Henslow, in the *Gardeners' Chronicle*, for January 25, 1908, was thoroughly appreciated.

It seems more probable that the Apple is the Quince, and this change will be made in the next edition of the little book.

Inasmuch as the Paliurus does not grow around Jerusalem, it can hardly be the Christ-thorn.

By "spelt," I suppose is meant Triticum spelta, and this, so far as I know, is not grown in Palestine at all, hence Vicia ervillea appears more likely to be the plant intended by "rie." *J. E. Dinsmore, The American Colony, Jerusalem, Palestine, February 22, 1908.*

———With regard to Paliurus, if it does not *now* grow around Jerusalem, it must have been exterminated since 1889; for Dr. Tristram says (*The Natural History of the Bible*, p. 428):—"The Arabs of the Jordan Valley at the present day . . . confine the name Sanur to the P. aculeatus, or Christ's Thorn. . . . It is common about Jerusalem."

With regard to the Kussemeth, the Hebrew word translates "spelt" (in B.V.); no one knows what it actually was, but as it always accompanies a cereal in the three passages, it is supposed to have been some variety of Wheat. The *modern* term refers to a Wheat of a cooler climate. I have seen it cultivated in Switzerland, but it may stand for numerous sorts. At the present day nearly 20 varieties of Wheat are known in Egypt, and one Triticum tricoccum has been found in the tombs. De Candolle (*Origin of Cultivated Plants*, p. 363) says:—"I imagined it was perhaps the allied form T. monococcum," not now in Egypt. The Arabic words for Wheats of Egypt are numerous; but neither Kirsenni nor Chirsanat (given by Tristram) occurs amongst them. No one has suggested Vicia ervillea; this would have been more likely included as pulse. It has only been lately introduced into Egypt. *George Henslow.*

TREES AND SHRUBS.

DWARF CONIFERS.

A CONSIDERABLE number of dwarf Conifers are suitable for cultivation on the rockery or in small beds. Few of them ever grow more than about 4 feet in height, and require many years to attain even that size. In habit they are either spreading, or upright and compact, or, as in the case of some of the Pines, ruggedly picturesque. Some of them are natives of mountainous regions, while others have originated as garden varieties, but all are equally at home on the rockery or similar positions where they have a deep and fairly dry root-run, as they are very impatient of too much moisture at the root.

JUNIPERUS.

J. japonica var. aurea (Hort).—I have never been able to quite make out exactly what this plant is. According to the *Kew Hand-list* it is a synonym of J. chinensis var. aurea, but the latter is an upright-growing plant of a bright yellow colour, very handsome, but rather tender, while J. japonica var. aurea is a spreading plant with long branches irregularly placed, but usually arranged in a flattened, fan-shaped manner. The colour is a shade of deep orange-yellow. It is an easy plant to grow, and will attain to a good size, but may easily be kept within bounds.

J. Sabina (the Savin).—This is a well-known dwarf, spreading shrub of irregular habit, with dark green foliage and purple berries. There are some four or five varieties, of which the var. procumbens (the Waukegan Juniper) and var. prostrata (both of them neat-growing, prostrate plants), var. tamariscifolia, a round, dwarf bush with glaucous foliage, and var. variegata, with creamy-yellow or white variegation, are the best.

J. virginiana var. globosa is a round, bushy plant, attaining a height of no more than about 3 feet, with bright green tufted branches tipped with bronze in the winter. It is a comparatively new plant, and is likely to be an acquisition for positions suitable to it.

J. virginiana var. kosteriana.—This resembles the typical Red Cedar in general appearance, except that the growth is somewhat coarser, and the plant does not grow more than about 2 feet or so in height. It is of a round, compact habit, and is of a bright green colour all the year round.

J. virginiana var. tripartita is a dwarf, spreading form, with sharp-pointed glaucous foliage and branches usually divided in threes. It is a fairly fast-growing plant, and requires room to develop.

J. communis var. alpina (J. canadensis).—A form of the Common Juniper. This plant is found chiefly on the mountains in Northern Canada, though it also occurs in Northern Europe and Asia. It is a dwarf, spreading shrub, rarely more than 3 feet in height, with long, slender shoots symmetrically arranged, and clothed with narrow, sharp-pointed leaves marked with silvery lines. In winter the foliage assumes a bronzy tint. J. communis var. alpina aurea resembles the variety alpina except that it is of a bright golden tint in summer, changing to orange in winter.

CUPRESSUS.

C. Lawsoniana var. nana (dense).—This is a plant of compact habit, and it takes many years to reach a height of 4 feet or so. It is broadly pyramidal in shape, with dense, compressed foliage of a rich, deep green colour. It is a handsome plant, and very useful in a small state. There is a sub-variety (var. nana glauca) with a more pronounced glaucous hue than the variety nana.

C. obtusa var. pygmæa.—Although this is an old plant in English gardens, it is not at all common. It grows from 1 foot to 2 feet in height, and spreads symmetrically on all sides. Its neat habit and bright green foliage renders it a desirable plant for the rockery.

C. obtusa var. nana (densa).—This is an upright pyramidal, or broadly conical plant of slow growth and dense habit. The tufted foliage is of a deep green hue, and the plant can either be grown into a small specimen 6 feet or so in height, or be kept dwarf and spreading by cutting the leader away.

C. obtusa var. nana aurea resembles the variety nana in habit, except that it is not quite so dense, and is of rather freer growth. The colour is of a bright golden-yellow, which is effective all the year round, and especially so in winter.

C. pisifera var. nana aurea variegata is a comparatively rare plant, growing about a foot in height, and spreading horizontally on all sides. The growth is dense and bright green in colour, splashed and spotted with pale gold.

THUYA.

T. occidentalis var. globosa.—The habit of this plant is well described by its name, the upright growths springing from the base, and composing a rounded, compact plant suitable for the rockery or a position where a dwarf, formal plant is required. In summer the foliage is of a bright, grass-green hue, changing to a brownish tint in winter.

CRYPTOMERIA.

C. japonica var. elegans nana.—This is a dwarf plant with soft, linear leaves densely crowded on the short branches. In summer it is of a bright, cheerful green, which changes to a bronzy-crimson in winter. A neat and effective plant at all seasons.

TSUGA.

T. canadensis var. albo-spica.—Strictly speaking, this is not a dwarf plant, as it attains to a height of 10 feet or so with age, but its rate of growth is slow, and its habit and colour so pleasing that it is worthy of inclusion among those plants suitable for the back of the rockery. The branches are slender and gracefully arching, and clothed with small leaves tipped with silvery-white. It succeeds best in a moderately dry situation sheltered from cutting winds.

PICEA.

Most of the dwarf forms of Picea are varieties of P. excelsa (the Common Spruce), all of which will grow best under rather moister conditions than most of the dwarf Conifers. The best of the dwarf Spruces are P. excelsa var. clanbrassiliana, var. clanbrassiliana elegans, var. dumosa, var. Gregoryana, and var. pygmæa, all of which have a certain resemblance to each other, being of a round, compact habit with dense, crowded foliage of varying shades of green. P. excelsa var. Remontii is a dwarf form of erect habit, the branches all having an upright tendency, while the colour is of a bright, cheerful green all the year round. It is a miniature, well-grown specimen Spruce, and is perhaps the best of its class.

ABIES.

A. balsamea var. hudsonica is a small, stunted Silver Fir, with leaves about an inch long, deep, shining-green above, and silvery beneath. In habit it is irregularly pyramidal, with short, thick branches on which the foliage is densely crowded. Unfortunately it is liable to attacks of scale, and does not always thrive as well as it might do.

PINUS.

P. Laricio var. pumila.—This variety of P. Laricio is a dwarf, dense Pine rarely more than 2 feet in height, with short branches having the foliage clustered at the ends. It is a more picturesque than handsome plant, but has a distinct appearance that is quite in keeping if grown on the rockery.

The *var. pygmæa* closely resembles mula.

P. montana.—This variable species is found throughout the mountainous regions of Central Europe at elevations of 5,000 feet or more. At its best it rarely exceeds 15 feet or so in height, but is more often met with about half as high. It is a branching, bushy shrub with leaves about 2 inches long, densely clustered on the stems, and dull to dark green in colour. Its slow growth and dense, branching habit render it peculiarly useful on the rockery. There are several varieties of this Pine, the best dwarf ones being var. Mughus and var. Pumilio, both of which are preferable to the type as dwarf plants.

P. sylvestris var. aurea is a slow-growing form of the common Scotch Pine (not Scotch Fir, as it is often erroneously called), with leaves 2 inches to 3 inches long, of a glaucous-green tint in summer, changing to a bright golden hue in winter.

P. sylvestris var. globosa. This is a round, compact plant with foliage of a bright, glaucous tint. In habit it is pyramidal, with the side branches usually ascending, and keeps its compact, globose shape throughout. Essentially a plant for a dry spot.

P. Cembra var. pumila.—A slow-growing Pine, this variety rarely reaches a height of more than 3 feet. In habit it is spreading, or even creeping under certain conditions, the irregular branches being clothed with silvery leaves about 2 inches long. It is an old introduction from North-Eastern Asia, but is not often seen.

P. Strobus var. nana. This is a dwarf form of the well-known Weymouth Pine, and makes a small bush about 3 feet or so high, with numerous slender branches clothed with soft, light green leaves marked with silvery lines. When well grown and flourishing, it is a graceful and distinct-looking plant. The variety prostrata resembles the variety nana, except that the habit is less erect and more spreading. *J. Clark.*

LILIUMS AS BEDDING PLANTS.

FOR producing a bold floral effect in the flower garden, few subjects are more suitable than the larger-flowered species of Lilium, such as L. longiflorum, L. auratum, L. speciosum, &c. Many of these Lilies have varieties that, from a garden point of view, are even more desirable than the type. At fig. 76 is represented a bed of the beautiful variety of L. longiflorum, known as eximium, growing in a bed in Kew Gardens in association with a hardy Heath. These large-flowered Liliums are often associated in beds with other Ericaceous plants, such as Azaleas, Rhododendrons, and Kalmias.

The protection afforded to the Lilies by the shrubs during the early period of their growth enable the bulbs to be planted early, and this gives the plants a good start. The effect of the flowers is also enhanced by their setting of foliage beneath and around them. The conditions of soil and moisture in such beds are suitable to the bulbous plants, and especially is this method of planting valuable in the case of large beds near to a lake or on a large lawn, the flowers of the Liliums relieving the somewhat monotonous greenery of these early-flowering shrubs. Lilium longiflorum var. eximium is known as the Bermuda Lily, and has by some botanists been raised to specific rank.

FIG. 76.—LILIUM LONGIFLORUM EXIMIUM FLOWERING IN A BED CONTAINING ERICAS.

KEW NOTES.

THE CONSERVATORY.

THE rich yellow flowers of Tecoma Smithii, although somewhat out of season, are even more welcome than they were in early winter. The plants of Kalanchoe Dyeri, a species introduced from British Central Africa a year or two ago, are carrying useful heads of large white blooms. Another plant of recent introduction from Africa is the yellow-flowered Coreopsis Grantii. Dicentra (Dielytra) spectabilis is a common hardy plant, albeit a most useful one for greenhouse decoration when brought along gradually in heat. Several large specimens of Jasminum primulinum in 12-inch pots are thickly clothed with yellow flowers. The secret of success with this plant appears to be to encourage the development of as much young growth as possible, and by plunging the plants in the open air during the summer and autumn enable them to thoroughly ripen the shoots. During the winter, place them in a cool house, where only sufficient heat is maintained to prevent frost, and give the plants very little water.

A useful Coleus to follow C. thyrsoideus is C. shirensis. The colour of the flowers is not such an effective shade of blue, being a dark purplish-blue, but it is nevertheless a valuable addition to the greenhouse plants. Several large specimen Camellias planted out in one of the beds are blooming freely. C. reticulata is by far the most beautiful, with large semi-double bright rose-coloured flowers.

The west wing of the house is almost entirely devoted to Ericas, Acacias, &c. At the present time the pride of place amongst the subjects in flower must be accorded to a large

plant of Darwinia (syn. Genetyllis) Hookeriana, a heath-like plant belonging to the natural order, Myrtaceæ. The small flowers are borne in terminal heads, usually six together, enclosed in a brick-red coloured involucre. These last in perfection for three or four months. A number of plants of Eriostemon affinis and E. myoporoides are clothed with white flowers tinged with pink in a young state. The Australian representatives of the Heaths, namely, the genus Epacris, make a good show with their long slender shoots thick with flowers. Most of the plants are garden hybrids.

Several species of Acacia form useful decorative subjects grown in pots, while others are better planted out in large structures, notable amongst the latter being the Silver Wattle, A. dealbata. The best plants flowering here in pots are A. Drummondii, A. hastulata, A. obliqua, and A. longifolia var. magnifica. The Correas are another Australian family deserving of mention, the most useful decorative plants being C. speciosa and the varieties curiosa, magnifica, and major, also C. cardinalis. Erica Veitchii is grown as a pot plant, and very useful it is. The plants grown outside at Kew have suffered rather badly from frosts, except where planted in a sheltered position or afforded protection.

Boronia megastigma and B. fastigiata (syn. polygalifolia), with pink flowers, will soon be at their best. Olearia ramulosa has small, pure white, Daisy-like flowers. Also deserving of note are Chorizema cordatum flavum and Helichrysum humile.

FORCED TREES AND SHRUBS

are extensively used for the decoration of this house in late winter and early spring. A few of the best at present in flower are Spiræa prunifolia flore pleno, Prunus triloba flore pleno, Prunus pseudo-cerasus James H. Veitch, Pyrus floribunda and the variety atrosanguinea, Viburnum Opulus var. sterile, Rhododendron sinense, better known in gardens as Azalea mollis, R. Cunningham's White, R. fastuosum, Staphylea colchica (delightfully fragrant), Kerria japonica flore pleno, Lilacs Charles X., Marie Legraye, and Madame Lemoine.

EARLY-FLOWERING BULBS.

Amongst single Tulips the tall orange-scarlet Prince of Austria is prominent; Mon Trésor (golden yellow), Rose Gris de Lin (rose-pink); Double Tulips: Salvator Rosa (deep rose), Couronne d'Or (yellow-shaded orange); Narcissus: Glory of Leiden, Golden Spur, Obvallaris, Sir Watkin, Grand Monarque, Jaune Suprême; Crocus species, including C. biflorus (white, striped black), C. chrysantha (yellow), C. Imperati (dark violet), C. Sieberi (purple); Crocus varieties: King of the Blues, Sir Walter Scott (striped), Reine Blanche White and Cloth of Gold; Hyacinths (single): Grand Maitre (porcelain blue), Baron van Thuyll (dark blue), Baroness van Thuyll (pure white), MacMahon and City of Haarlem (yellows), Moreno (pink). A large group of seedling Hippeastrums furnish the brightest patch of colour in the house. Several of the dark red Sir William type, for which the Kew collection is noted, are prominent. *D. D.*

LAW NOTE.

ASSESSMENT OF GREENHOUSES.

CONSIDERABLE satisfaction appears to have been caused amongst growers, as well as some of the trade papers, by the result of an Assessment Appeal heard recently before the District Committee of a certain County Council in Scotland. The appeal was made by a firm of market gardeners, who contended that they were entitled to a reduction in rates under the Agricultural Rates (Scotland) Act 1896, in respect not only of the land cultivated by them, but also of other portions of their land covered by greenhouses. Counsel for the growers in question contended that the greenhouses were used exclusively for the cultivation of Tomatos and for horticultural purposes, and that the mere fact that the climate necessitated a covering of glass and artificial heat did not exclude the occupiers from the benefit of the Act. After adjourning the matter for further consideration, the committee finally allowed the appeal, and accordingly the growers were held entitled under the Act to a reduction of rates in respect of their glasshouses as well of their uncovered land.

It is, of course, natural for English growers to assume that what is reasonable in Scotland is equally reasonable in England, and, accordingly, to draw the inference that they themselves are entitled to claim similar relief. Unfortunately, however, there appears to be serious ground for believing such an inference to be entirely incorrect. In the first place, it must be remembered that there are two Agricultural Rates Acts of 1896, one applying only to England and the other only to Scotland, and there is considerable difference in their wording.

Both Acts, it is true, are intended to confer special privileges, in the matter of rating, on agriculturists, but the systems both of land tenure and of rating differ very considerably in the two countries, and it is, therefore, inevitable that the Acts dealing with this subject should also differ.

The first point to be noted is that whereas the benefit of the English Act is conferred on occupiers of "agricultural land," that of the Scotch Act is extended to occupiers of "agricultural land and heritages." But perhaps the most important point to be observed when comparing the two Acts is the marked distinction which the English Act draws between "land" and "buildings." Section 1 sub-section (2) of this Act expressly provides (inter alia) that it shall not apply to a rate which the occupier of agricultural land is liable, as compared with the occupier of buildings and other hereditaments, to be assessed to, or to pay, in the proportion of one-half or less than one-half.

[It is to be observed that no similar clause is contained in the Scotch Act.]

This provision seems therefore to be the keynote of the whole question, and the pointed distinction which is there drawn between "land" and "buildings" affords the ground upon which English nurserymen would be held to be debarred from claiming relief in respect of their greenhouses under the English Act, although their Scotch brethren would apparently be entitled to claim relief in similar circumstances under the corresponding Scotch Act. It may be noted that the Scotch Act does not specifically mention nursery grounds, though the English Act does so; this, however, does not affect the point with regard to the distinction to be drawn between land and buildings, which it is now desired to emphasise.

In the case of the English Act, the House of Lords decided a few years ago that glasshouses in or on a market garden, if buildings, must for the purpose of the English Act of 1896 be rated as "buildings" and not as "agricultural land," thereby losing the benefit of the Act. As many readers are doubtless already aware, the appellant in the case now under consideration was a market gardener and nurseryman occupying a piece of land rather more than four acres in extent, on which 57 glasshouses and greenhouses of various sizes were erected. The special case on which the appeal was founded stated that these houses were used for the purpose of growing Tomatos, Cucumbers, and Grapes, and, to a smaller extent, other vegetables, for the purpose of sale. The plants and crops grown therein were watered and heated by artificial means, were grown upon soil placed upon prepared beds inside the houses, and matured much earlier than in the open ground. The vines were planted inside the houses, and the roots ran partly in the soil under the houses and partly passed through the apertures in the walls into the soil outside. Fifty-one of the glasshouses were thus used for growing vines. In the Cucumber houses (which comprised six out of the 57 houses) there were, inside the houses, dwarf brick walls supporting corrugated iron sheets, upon which sheets earth taken from other parts of the nursery ground was placed. In this earth, so placed upon the iron sheets, the Cucumber plants were planted. Beneath the iron sheets, and between them and the ground, there were hot-water pipes. The area actually occupied by the 57 houses was rather more than two acres, and the rest (also rather more than 2 acres) consisted merely of vine borders paths, and the stoke-holes. The whole of the houses were built upon dwarf brick walls like an ordinary greenhouse. Under these circumstances, the Law Lords were unanimous in their opinion that, for the purpose of the English Act (a) buildings must be treated as distinct from land; (b) the greenhouses must be treated as buildings; and, accordingly (c) that the relief granted by the Act of 1896 to agricultural land could not be claimed in respect of such greenhouses.

It is, of course, important to bear in mind that there are certain other statutes giving relief to cultivated land which are worded quite differently to the Act of 1896, and in such cases, by reason of the manner in which they are worded, relief under these statutes may still be claimed in respect of such land, even though it be covered by greenhouses.

The Public Health Act, 1875, for instance, provided that the occupier of any land used as (amongst other purposes) market gardens, or nursery grounds, "shall be assessed in respect of the same in the proportion of one-fourth part only of the net annual value thereof." A good many years ago a market gardener claimed relief under this Act in respect of the occupation of a piece of land upon which were built 16 greenhouses or glasshouses, and these practically covered the surface of the land; they were built on brick foundations, and were used for the purpose of growing fruit or vegetables for sale in the ordinary course of business. In this particular case the grower was successful, as the Court of Appeal held that upon the wording of this particular statute a garden was none the less a garden because it was effectually protected by glass against the weather or by high walls against the wind.

It will be seen, therefore, that sometimes a greenhouse is in the legal sense "a building," and sometimes it is not, the matter turning upon the wording of the particular Act of Parliament which may be under consideration at the moment. We have, therefore, one more example of the urgent necessity for the codification of the law relating to this complicated subject. Enough has perhaps been said to show that because a grower in Scotland has succeeded in winning an assessment appeal, it by no means follows that his English brother would prove equally successful under somewhat similar circumstances, and so far as the case recently heard in Scotland is concerned, it is clear that English growers who are tempted to appeal against their own assessments on the strength of it, would probably find that they were throwing their money away without the least prospect of success. *H. Morgan Veitch.*

VEGETABLES.

A NEW EARLY TURNIP.

FOR many years the best and earliest variety of Turnip was the Early Milan, either the white or red variety, but Little Marvel is a great advance on these, both in regard to earliness and quality. Early Milan, though a good early Turnip, matures quickly and soon becomes dry and flavourless. The newer variety has a rounder root than Early Milan, is more solid, and is of excellent quality. It was raised by crossing the White Early Milan with the variety Jersey Lily: the last-named is a splendid root, and the new form has much of its good qualities with increased earliness. As a first crop variety in the early spring, Little Marvel is valuable, and I not only sowed it for the earliest crop out-of-doors, but also forced it in frames where it matured rapidly and yielded roots of splendid table quality. These quick-growing varieties are also valuable in other respects, for by sowing a small quantity of seed at short intervals, sweet roots of a size suitable for table purposes are always available. In some soils the Turnip does not remain sound after it is fully grown, it is therefore best to sow often, using a small quantity with [illegible] such as the one under a tree. I do not recommend the variety for storing, the roots should be used direct from the soil to [illegible].

CULTURAL MEMORANDA.

JASMINUM PRIMULINUM.

SOME three years ago I sent to the Editor of the *Gardeners' Chronicle* a few notes respecting Jasminums in general, including J. nudiflorum. A correspondent subsequently took exception to my statement that this species was hardy. I now may be permitted to say that a plant has withstood 19° degrees of frost this winter, and only the unripened tops of the leading growths have suffered any injury. It cannot, therefore, be tender, as the plant is growing against a wall facing due east. Another plant, being the first we purchased, was planted against a wall facing to the south, and therefore is sheltered. This specimen presented a mass of golden-coloured flowers on the 2nd of the present month, and all of them appear semi-double. This species forms a good succession to J. nudiflorum. Open walls are not too well furnished with flower subjects during the first four months of the year, and I would advise those who have not given J. primulinum a trial, to forthwith plant it in the warmest position they can give it. *J. Mayne, Bicton Gardens, Devonshire.* [The specimens received from our correspondent were very beautiful, and their appearance would have led us to suppose they were cultivated indoors.—ED.]

GUNNERAS.

THESE plants produce the finest leaves when their roots can reach the water. The crowns should therefore be planted on the margin of the stream. Plants in these conditions succeed well in these gardens. When the foliage is tied down early in winter, we cover each crown with the fading leaves. This affords some protection to the young leaves as they develop in spring. The flower-spikes should be removed as soon as they are observed, if the greatest size is required in the leaves. We seldom do this in our case, as the appearance of the inflorescence is appreciated. *J. Mayne, Bicton Gardens, Devonshire.*

The Week's Work.

PLANTS UNDER GLASS.

By THOMAS LUNT, Gardener to A. STIRLING, Esq. Keir, Perthshire, N.P.

Achimenes.—The corms should be started into growth in successional batches, so as to provide a continuous supply of flowering plants for the warm conservatory. As soon as they have made shoots 2 to 3 inches high, they should be potted, placing them in pots, pans, or baskets, but in either case allowing each plant about one square inch of space. A suitable potting compost for these plants is one consisting of light sandy loam, leaf mould, peat and sand in equal proportions. Cultivate the plants in a stove temperature until the flowers appear, keeping them very near to the glass. They will require the support of neat stakes, which it will be necessary to hide from view as much as possible. When the plants are growing freely, they may be fed liberally with liquid manures. As soon as the flowers commence to open, remove the plants to a cooler atmosphere, turning them round once each week to prevent them getting one-sided. After they have finished flowering, gradually withhold water from the roots, and eventually place them in a dry position in the stove. When the foliage is quite past, the pots or pans may be placed on their sides for the winter.

Gardenias.—Plants that have set their flower-buds will require frequent applications of liquid manure at the roots, Gardenias being gross-feeding plants. A little artificial manure may also be scattered over the surface of the soil once a fortnight. Syringe the plants twice each day in favourable weather, keeping them in a stove temperature. Be careful to prevent mealy bug becoming common on the plants, or it will cause much injury. Gardenias thrive best when planted out in a bed over bottom heat, but before being planted out in this manner, it is necessary to satisfy oneself that they are perfectly free from bug, it being inconvenient to cleanse dirty plants after they have been planted, as the insecticide is apt to get down to the roots. Gardenias should be exposed to the full sunshine, except when they are in full bloom, at which time a little shading helps to prolong the season of the flowers. An abundance of moisture is necessary, both in the atmosphere and at the roots. Cuttings may be made of the young growths if it is wished to raise further plants. Such cuttings should be inserted in sandy soil and placed in a temperature 70° to 75° at night. They will make nice flowering plants by the month of March next year.

Ixoras.—These plants should be treated in much the same manner as Gardenias. Any repotting that is required may now be carried out. Unless the loam is of a light fibrous nature, it will be better to use peat and sand exclusively, mixing with the compost a small quantity of broken bricks and charcoal. Ixoras require an abundance of water in the season of growth; therefore the pots should be provided with ample means of drainage. They are not such gross-feeding plants as Gardenias, and care must therefore be exercised when affording manures that the applications are of medium strength only. Weakly diluted manure water from the farmyard is one of the safest stimulants for Ixoras. Like Gardenias, they are subject to attacks of mealy bug, and will require to be kept clean in the same manner. They should be fully exposed to the sunshine, and the atmospheric temperature should not fall lower than from 70° to 75° at night. When in full flower a little shade from sunshine is advantageous.

THE FLOWER GARDEN.

By W. FYFE, Gardener to Lady WANTAGE, Lockinge Park, Berkshire.

Pruning of Roses.—The pruning of Roses may be commenced at any time after this date, provided that favourable weather occurs. Pruning generally has the result of increasing the size of the flowers, but it is not advisable to prune strong-growing varieties severely, as this would tend to make the plants produce even stronger shoots and but few flowers. On bushes or dwarf plants the strongest and best ripened shoots of last season may be left 8 to 10 inches long. All weakly shoots from the centre of the plants should be removed, and growths of medium strength cut to the length of 1 or 2 inches, making the cut immediately above a well-developed bud, choosing one that points in the direction the shoot is desired to grow. In the case of standards, it will be necessary to prune more severely, in order to maintain the "heads" in a good form. If the plants are weakly, each shoot may be cut to two or three buds, but if vigorous, not more severely than to four or five buds. In the case of Hybrid Tea varieties, cultivated as bushes, it may be advisable to give more encouragement to the stronger shoots, as these are valuable in schemes of garden decoration. Cut out all weak shoots and shorten the more vigorous growths to half their length. Any plants of this type which are cultivated as climbers, may have their growths left almost their entire length.

Newly-planted Roses.—When the plants are seen to be growing from the base, these should be cut back to that point. If the beds were mulched with farmyard manure after planting, it will only be necessary now to lightly stir the surface of this mulching, but otherwise a dressing of rich soil or well decomposed manure would be beneficial.

Specimen plants in the flower garden.—Standards are among the most effective of trained specimens for use in bedding. For training in this fashion, such species as Fuchsias, Lantanas, Heliotropes, Daturas, Plumbago capensis, Streptosolen Jamesonii, Veronica Andersonii, Swainsonia alba, and Calceolaria amplexicaulis, &c., will be found useful. Plants intended for use in this manner should be pruned to induce them to form globular heads, excepting the last-named species. Place the plants for the present in moderate heat, and when they commence to show growth shake away a portion of the old soil from the roots, slightly trim the roots, and re-pot the plants into pots of the same size as those from which they were removed. For the potting, employ a moderately rich compost, and after the plants have become established in the new soil gradually accustom them to more ventilation and a lesser degree of fire-heat. If it is intended to cultivate standards from cuttings, the cuttings should be grown to the desired height, removing all side shoots. An exception is again made in respect to Calceolaria amplexicaulis, this species affording an excellent effect when 5 feet high and furnished with side shoots. In the cultivation of such a plant, the side shoots should be stopped at the first leaf until the plant has attained its desired height.

Early-flowering Chrysanthemums.—The stock of particular varieties of early-flowering Chrysanthemum may be increased by dividing the old stools and potting the divisions into small pots. These should afterwards be placed in unheated frames where they may remain until they have made roots. When the divisions have become well rooted, they may be removed to a sheltered position out-of-doors. The beds or borders in which it is intended to cultivate these plants should in the meantime be prepared for them by having the ground deeply dug, and by receiving an application of farmyard manure, which should be well mixed in the soil during the process of digging. The Chrysanthemums may be planted out into their permanent positions at the middle of May. Some of the newer varieties possess certain shades of colour which are as novel as they are beautiful.

THE KITCHEN GARDEN.

By E. BECKETT, Gardener to the Hon. VICARY GIBBS, Aldenham House, Elstree, Hertfordshire.

Hoeing.—There is no more useful or important implement for use in the kitchen garden than the draw-hoe. Sufficient importance is not generally attached to the need that exists for the stirring of the surface soil. The hoe can be employed at no season of the year to better advantage than during the latter part of March and early in April; this applies equally to all localities and every kind of soil. But especially is this the case where the soil has been broken up to a good depth. Hoeing breaks the crust which has naturally been formed by the wintry rains and snow; it stimulates the growth of the vegetables, and at the same time does much towards keeping the ground free from weeds. Among such crops as Spring Cabbage, Winter Spinach, and autumn-sown Onions the surface soil should be stirred at least twice each week. The Dutch hoe is a very valuable tool for clearing the ground of weeds, but it is of little use on very heavy land at this time of year.

Carrots.—The principal sowing of Carrots may now be made on ground which has been well tilled but has not been freshly manured. Carrots are probably one of the most uncertain and unreliable crops cultivated in the kitchen garden, except in a few parts of the country where the soil specially suits them. In order to obtain specimen roots from many kinds of soil, special care has to be taken in preparing such soil. Wire-worm and the Carrot fly are two most troublesome pests. For the latter I have found the use of vaporite very beneficial. The land should also be thoroughly dressed before sowing the seed with fresh soot, lime and burnt garden refuse, the latter material being one of the finest stimulants that can be given to the soil of the kitchen garden. On very wet pasty soil it is a capital plan after drawing the drills to strew a little finely-sifted soil in them before sowing the seed and again afterwards. This will assist the young seedlings to make a good start. If extra fine specimens are required for any particular purpose, it will be necessary to bore deep holes with an iron bar and fill these in firmly with finely-sifted sandy soil to which may be added to every barrowful a 6-inch potful of bone meal and half a peck of wood ashes. Nothing is more suitable than old compost saved from the potting shed. New Intermediate and Prize-winner are among the finest types of long Carrots, and Model is an excellent stump-rooted kind adapted for cultivation on shallow soils. Early crops under glass should be thinned as they become ready, and sufficient air should be admitted to the structure to prevent them from becoming drawn. Fumigate with XL-All vaporiser if any signs of green fly appear.

Mint and Chervil.—Green Mint is always in great demand at Easter time. Fortunately, this herb may be forced easily, and a good batch of roots should now be lifted and either placed in boxes or planted out and forced in a gentle heat. Chervil should be treated in a similar manner.

Spinach.—Make a good sowing of Perpetual Spinach in any out-of-the-way place that is suitable for the purpose.

FRUITS UNDER GLASS.

By T. COOMBER, Gardener to LORD LLANGATTOCK, The Hendre, Monmouthshire.

Fig trees in borders.—Trees bearing heavy crops of fruit and growing in borders already well filled with roots, need liberal supplies of nourishment. This nourishment may be applied in the form of top-dressings and waterings with liquid manure. Fig trees growing under such conditions require a large quantity of water at the roots, partly owing to the large transpiring surfaces presented in the leaves. Attend to the stopping of shoots, thinning them out as required, and training those which remain in such a manner that the trellis will be evenly covered, taking care to prevent overcrowding. The value of the second crop will depend upon the strength of the trees. The strongest shoots should be allowed to share amongst them the whole of the crop, even though three fruits have to be allowed upon a single shoot. To prevent red spider, attend to the ventilating of the house, and thoroughly syringe the trees twice a day in favourable weather. Trees for supplying late crops will need to be disbudded sufficiently to prevent their shoots becoming crowded, and the permanent shoots may be stopped at the sixth leaf. These shoots will present various stages of development, and therefore the supply of fruit will extend over a considerable season. For the latest crops, the variety of Negro Largo is valuable, especially if the trees are started into growth sufficiently early to enable them to ripen a second crop of fruits.

Mid-season Peaches.—The trees that will ripen fruits at mid-season have now flowered, and they may be afforded rather more heat as soon as the fruit commences to swell freely. If it is desirable, the maturing of the fruit may be advanced by making the best use of the sunshine, or, on the contrary, it may be retarded by allowing atmospheric temperature to be rather less than that usually recommended. Whether it is necessary to force or retard the crop will depend largely upon the collection of varieties in cultivation. Let disbudding be done gradually, in order that no severe check may be imposed upon the tree at any particular time, reserving those shoots which are most promising and in the best positions. The youngest growths can be usually removed by the fingers, but should any have been left until they are woody, it will be necessary to use a sharp knife. Commence to train the shoots whilst they are young and pliable, and continue the work as may be necessary.

Affording of water.—The construction of fruit borders varies so much that it is difficult to give definite directions in regard to the amount of water they may require, but the affording of water is a matter that requires great care. Readers are advised to procure one of Mr. Kirk's border testers (see fig. 22 in the issue for January 18), and after using this implement they will be fully convinced of the ease in determining accurately when a border is needing water with the assistance of some such means.

THE ORCHID HOUSES.

By H. G. ALEXANDER, Orchid Grower to Major G. L. HOLFORD, C.V.O., C.I.E., Westonbirt, Gloucestershire.

Odontoglossums.—During April and May O. crispum and other spring-flowering species and Odontoglossum hybrids may be expected to make a fine display. In the latter part of the past winter the plants suffered from insufficient sunlight, but the favourable climatic conditions that prevailed last autumn were certainly advantageous. If the specimens that will flower this season were exposed at that period to the full sunlight and were cultivated in a structure that was properly ventilated, the specimens will now be in course of developing strong flower-spikes. Plants already in full flower, or those just about to expand their buds, should be grouped together where they can be given a little extra shading, and where they will not be subjected to overhead spraying. Other plants that are only as yet developing the flower-spikes, may have the foliage syringed daily during favourable weather, and they should be shaded only during the middle hours of the day. A constant circulation of air must be maintained in the structure containing the Odontoglossums, and the atmosphere should be kept well charged with moisture. The plants themselves will need liberal supplies of water at the roots. Great care is necessary to preserve the flower-spikes and buds from the depredations of slugs and snails. Traps should be set for these pests, and they will need to be examined each night by the aid of a lamp. If a little cotton wool be placed around the base of each flower-spike, it will often prevent injury from slugs. In the case of a plant possessing more than ordinary value, the safest plan is to place it on an inverted pot, standing the inverted pot in a bucket filled with water. But even if this precaution is taken, constant care will be necessary, as small slugs and snails are often found hiding in the potting materials. Green and black fly and thrips are also troublesome at this season, and they must be prevented from getting upon the young growths and flower-spikes. On the first discovery of these insects the house should be vaporised, choosing a calm night for carrying out the operation. The foliage of the plant should be quite dry at the time of the operation, but the atmosphere may be moderately moist, as the fumes will be more effective under such conditions.

Repotting.—Although early autumn is generally considered to be the better time for overhauling these Odontoglossums, I do not hesitate to repot a plant that is not flowering, but is in need of new rooting materials. In these gardens we employ a similar potting compost to that I have advised for Miltonias, but some crushed crocks and charcoal may be added to that compost. It is essential that the pots should be well drained, and, therefore, they should be filled to one-third of their depth with clean crocks. Press the materials moderately firmly about the roots, and do not grow the plants in pots that are too large for them. After the potting has been done, exercise the usual care in regard to watering, paying special attention to the shading from sunshine, and to damping the surface between the pots. Spray the plants overhead occasionally in favourable weather, and encourage them to become re-established as quickly as possible.

Odontoglossum Edwardii.—The flowers of this species are somewhat small and less showy than many other Odontoglossums, but the colour is distinct, and the dull-branching scapes are attractive. The plants may be easily cultivated in the cool division. They are not free-flowering, but so far as small plants are concerned, this is an advantage, for they do not become exhausted by flowering before they are strong enough to do so without suffering injury. Any plants that require to be repotted may be given attention as soon as they have flowered, or the work may be done at the present time, if it can be seen that no flower-spikes will be produced. The roots of this species being large and more fleshy than those of most Odontoglossums, the rooting material provided for them should be made to contain a considerable quantity of roughly-broken crocks and charcoal. The plants will require pots rather larger in size than those employed for other species.

Odontoglossum Uro-Skinneri.—This species may be given the same treatment as Odontoglossum Edwardii, and will require attention at the present time in the matter of repotting or resurfacing, for new roots will soon commence to appear from the base of the partially-developed growths.

THE HARDY FRUIT GARDEN.

By F. JORDAN, Gardener to The DOWAGER LADY NUNBURNHOLME, Warter Priory, Yorkshire.

Fig trees.—It will now be safe to remove the protective material from the trees. If it is found that these latter have already commenced to produce shoots it will be necessary to remove such covering very gradually, that the growths may become inured to the influence of light and air. Some protection may, however, still be afforded at night time if there are signs of frost. If any pruning is necessary, treat the trees as I advised in the Calendar published in the issue for February 22. In the same Calendar directions were given for top-dressing trees growing in restricted borders, and for the making of new border and the planting of young trees.

Strawberries.—If preparations for making new beds have been carried out according to the directions published in the issue for February 8, the soil will have settled down sufficiently, and the process of planting may be commenced as soon as the weather is favourable and the soil is found to be in a suitable condition for being worked. Strawberry plants have suffered severely in the northern counties from frost and cold winds, and such plants should now be relieved of all damaged leaves.

Autumn-fruiting Strawberries.—These plants require a deep rooting medium and a rich soil. Such varieties of the perpetual fruiting type as St. Joseph and St. Antoine de Padoue are usually propagated from layers, and if planted under the shade of a north wall, are valuable late in the season. They may also be layered in July, and cultivated in pots, in which case the runners and flower-spikes should be picked off as they form, until the plants are required to produce fruit, when they should be placed in a cool house in order to ripen their fruits in October. Autumn-fruiting Strawberries may also be obtained from seed. Seedling plants are more vigorous than those raised from layers, especially if the layered plants have been allowed to remain too long in the same position. If propagation is effected from layers, then it is best to layer only the strongest runners early in the season and make fresh beds early each year, planting them at distances of 18 inches apart.

Alpine Strawberries are best grown from seed, and the present time is a suitable one for sowing seeds in boxes. Place the boxes in a moderate warmth and prick off the seedlings as soon as they are large enough to handle. Keep them in the same atmospheric temperature until the plants are established, then remove them to a cooler house or frame, and gradually harden them for planting out in May. Such varieties as Sutton's Large Red, Rouge Ameliare, and others may be seen fruiting most satisfactorily in September and October at Gunnersbury House Gardens, Acton.

Aphides or green fly.—These pests will soon occasion the fruit-grower considerable trouble. Apricot, Cherry, Peach, Nectarine, and Plum trees should be syringed with Quassia Extract, or some other approved insecticide, just before the flowers are about to open. The trees may then be expected to remain clean until the fruits have set, when it will be possible to renew the syringings.

THE APIARY.

By CHLORIS.

The Bee or Wax-moth.—Hives that are usually attacked by this pest are those containing weak colonies, or in which there are crevices, either under the frame-ends or between the various parts of the hive, through which a grub may creep and thus be out of the reach of the bees. Hives, too, that are not clean, but in which the floor is covered with the debris from the unsealing of the cells during winter and early spring are often infested with the larvæ of this moth. When an examination of the hive is made, particular note should be taken of the under sides of the quilts and the frame-ends, together with the groove in which the comb has been secured. When the weather permits, the body or brood chamber of the hive should be lifted from the floor board and the rubbish brushed off, killing every grub that is seen. Wherever webby tunnels exist in the combs there are these pests found, and as they move on they injure the brood, and many of the immature bees are killed. These dead larvæ are carried by the bees to the outside of the hive and may often be found on the alighting board. Their death may also be caused by a shortness of food, but if the hive contains a plentiful supply of stores, the trouble may be attributed to the wax-moth.

The Italian bees will quickly extirpate these wax-worms, and it is surprising how quickly they will clear infested combs of the pest. Much of the mischief arises, not only from weak colonies, but from careless storing of surplus combs during the late summer and early autumn, and especially is it noticeable in the case of comb containing pollen. It will be noticed that the grubs travel from comb to comb by means of a silky web, therefore the frames should be stored far apart, so that the grub cannot pass from one to another. Many bee-keepers are careless with spare pieces of comb, which are cast about in a haphazard manner in the vicinity of the hives. The female of the wax-moth finds in this a suitable place for depositing her eggs, and the grubs on hatching creep into the hives.

EDITORIAL NOTICE.

ADVERTISEMENTS should be sent to the PUBLISHER, 41, Wellington Street, Covent Garden, W.C.

Letters for Publication, *as well as specimens of plants for naming, should be addressed to the* **EDITOR, 41, Wellington Street, Covent Garden, London.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Special Notice to Correspondents. *The Editor does not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editor does not hold himself responsible for any opinions expressed by his correspondents.*

Illustrations.—*The Editor will be glad to receive and to select photographs or drawings, suitable for reproduction, of gardens, or of remarkable plants, flowers, trees, &c., but he cannot be responsible for loss or injury.*

APPOINTMENTS FOR THE ENSUING WEEK.

SATURDAY, MARCH 21—
Meeting of the British Gardeners' Association at 7.30 p.m., at Carr's Restaurant, 261, Strand, London, for the purpose of establishing a London Branch. German Gard. Soc. meet.

WEDNESDAY, MARCH 25—
Roy. Bot. Soc. Exh. at Regent's Park.

AVERAGE MEAN TEMPERATURE for the ensuing week, deduced from observations during the last Fifty Years at Greenwich—42·7°.

ACTUAL TEMPERATURES:—
LONDON.—*Wednesday, March 18* (6 P.M.): Max. 43°; Min. 35°.
Gardeners' Chronicle Office, 41, Wellington Street, Covent Garden, London.—*Thursday, March 19* (10 A.M.): Bar. 29·8; Temp. 40°; *Weather*—Sunshine.
PROVINCES.—*Wednesday, March 18* (6 P.M.): Max. 45° Ireland S.W.; Min. 40° Liverpool.

SALES FOR THE ENSUING WEEK.

MONDAY—
Lilies, Border Plants, Bulbs, Azaleas, &c., at 12; Roses at 1.30, at 67 & 68, Cheapside, E.C., by Protheroe & Morris.

MONDAY AND WEDNESDAY—
Sale of Bulbs, &c., at Stevens' Rooms, King Street, Covent Garden, W.C.

TUESDAY, WEDNESDAY AND THURSDAY—
Important 3 days' sale of the whole of the Westfield Collection of Orchids, by order of Francis Wellesley, Esq., at 67 & 68, Cheapside, E.C., by Protheroe & Morris, at 1.

FRIDAY—
Herbaceous Plants, Hardy Bulbs, Liliums, &c., at 12; Roses at 1.30; Azaleas, Palms, &c., at 5, by Protheroe & Morris, at 67 & 68, Cheapside, E.C.

Maturation and Flowering. A comparatively new field of botanical investigation known as experimental morphology is gradually being opened up, and it is one which promises to yield results which will be valuable to the horticulturist. It is, of course, well known that many plants pass through a fairly definite life history which cannot be easily altered by outside influences. Thus, when a Mangold or a Carrot is sown, the first year of its life is generally devoted to storing up food in the swelling root, and during the next season the plant flowers and then dies. But yet in a field of Mangolds a larger or smaller number of individuals always "bolt," or run to flower during their first year, and this undesirable tendency is more apparent in some years than in others. It is obvious that the whole question of what causes a plant to direct its growth either towards vegetation storage, or towards flowering and fruiting, is one of considerable importance, for if we can explain what are the conditions that bring about the one or the other phase of the life history, we may succeed in gaining control over matters which it is at present beyond our power to influence.

It is gradually becoming clear that the production of flowers is due, in most cases at any rate, to the formation of certain definite substances in the plant, and that it is only when these are present that flowering becomes possible, provided, of course, that the physical conditions of heat, moisture, and the like are also favourable. Many carefully-conducted experiments have shown that the whole subject is intimately bound up with nutrition, but nutrition is a very wide term, and its course may be influenced by numerous external circumstances, such as light, temperature, &c. Many gardeners, for example, are fully aware of the disastrous effects that follow the application of raw manure to Roses at the wrong season, and during the winter that is now passing away, many of us have experienced the utmost disappointment owing to failures on the part of forced Hyacinth bulbs to produce blossoms. As to this latter example, there can be no doubt that the chief responsibility for the mischief rests with the cold, sunless periods that marred the summer of 1907, and interfered with the complex nutritive processes that ordinarily lead to the proper "ripening" of the bulb. Although we are not as yet in possession of all the facts which will one day enable us to say exactly what we really mean when we speak of ripening of bulbs, wood, &c., it is nevertheless becoming more and more obvious that the process depends on the accumulation of certain definite foodstuffs in, and probably also on the absence of others from, the plant. In other words, there are special substances, the preponderating influences of which act as the real agents in causing the plant, or parts of it, to pass from a vegetative to a floriferous phase of activity. Thus, it has been repeatedly proved by experiment that an excess of available nitrogen may delay the ripening of Mangolds, and we are perhaps justified in saying that the postponement in this and other similar cases is due to the accumulation of a certain class of food material which prejudicially affects the deposition of the substances essential to ripening. Probably, however, it would be more correct to say that the comparatively "raw" material continues to act as a stimulus to vegetative activity on the part of the plant which is unable to work it up into the appropriate chemical combinations at a sufficiently rapid rate. The stimulating effect which follows the excessive application of fertilisers usually makes itself apparent in the appropriate reawakening of vegetative activity appropriate because it is by means of its green-leaf mechanism that a plant is accustomed to deal with such substances.

It is possible in some cases to obtain a result in which the vegetative and reproductive aspects of the plant find a confused or mixed expression. This may happen if, for example, Roses are imprudently manured, for the raw foodstuffs serve to stimulate all parts of the plant to renewed vegetative activity at a time when the ends of the shoots have already been partly committed to development blossoms. An interesting experiment in this connection may be referred to. A certain Fern known as the Ostrich Fern, produces a number of green fronds arranged in a shuttlecock fashion, and these are followed later in the same year by an inner set of dwarf fertile leaves. But if the green leaves are removed as they unfold, those inner ones which should have been fertile are forced to grow as ordinary fronds, although they often exhibit intermediate stages between the forms of the barren and fertile fronds. In this experiment the balance of the plant is upset, and the substances which would have been diverted into the outer barren leaves have passed into the fertile ones, and have interfered in a corresponding manner with their development.

The process of "ripening off" is not the same for all plants, for some cannot be induced by any known modification of external conditions to deviate from their normal course of development, whether this lie in the production of leafy shoots on the one hand or of flowers on the other. Thus we may see that the matter is not a simple one, but it is one that is well worthy of close scientific investigation. Many plants are notoriously difficult to flower well. It may happen that in one locality the "conditions" are favourable, and no difficulty is experienced in obtaining blossoms. But why is this? Why is it that one despairing owner of evergreen masses of Gentians seeks in vain for the sheet of blue which comes with no trouble or credit to another? All that external conditions can do is to modify in a less, or, as unfortunately sometimes happens, in a greater degree, those nutritive processes which lead to the accumulation of the material that stimulates the flowering capacities, and, if allowed to form and to produce its full effect, determines the transformation of a vegetative to a flowering state.

It was not our intention to attempt to give a full explanation of the processes involved in ripening and maturation, for such an explanation still continues to elude the scientific investigator. Our endeavour has rather been to point out that in these matters certain definite problems are gradually formulating themselves, and that they are of interest, and perhaps also of importance, to the horticulturist, whilst from a still more general point of view it would be difficult to over-estimate their significance.

OUR SUPPLEMENTARY ILLUSTRATION.—The genus Cynorchis includes some 24 species, chiefly recorded from Africa, Madagascar, and the Mascarene Isles. Like many other tropical terrestrial Orchids, those species of Cynorchis which have been introduced to gardens have not been generally satisfactory, though, as in the case of many other reputedly difficult subjects, they grow with the greatest freedom in certain instances where their cultural requirements have been met. This may be said to be the case at the Royal Gardens, Kew, for Mr. W. WATSON, the Curator, not only succeeds in growing the showier species to perfection, but has even raised the handsomest Cynorchis × Kewensis from seeds obtained by crossing C. Lowiana and the species C. purpurascens, some of the plants so obtained flowering at Kew frequently with 18 spikes of flowers. Cynorchis purpurascens, from Madagascar, was illustrated from specimens obtained from Kew in the *Gardeners' Chronicle* for April 9, 1904, p. 227. In habit of growth it resembles C. Lowiana in being generally monophyllous. The inflorescence, however, bears from 15 to 30 rosy-mauve flowers, smaller in size than those of C. Lowiana. Cynorchis compacta is a South African species of much smaller growth than the others mentioned, but bearing profusely its spikes of white flowers. This species has often flowered at Kew, and in Baron SCHRODER's gardens at the Dell, Egham. Cynorchis villosa is a Madagascar species,

having erect racemes of very hairy, white and lilac-coloured flowers. C. Lowiana, which is figured in our Supplementary Illustration, is one of the prettiest of the Madagascan species. It has the small lateral sepals coloured light green, and the showy labellum bright rose-purple, the spur being clavate. It was the seed-bearing parent of C. × kewensis. Cynorchis grandiflora has slender green leaves, and usually produces one-flowered scapes, the labellum being of rose-purple colour, and the outer segments green, spotted with brown. It was illustrated in the *Gardeners' Chronicle* for February 18, 1893, p. 197. The experience at Kew proves that there is no reason why these pretty species of Cynorchis should not be successfully grown in gardens as ordinary warmhouse plants, provided their regular seasons of growth and rest are observed. At Kew the plants are rested from the end of December until the beginning of May, when they are turned out of their pots, the old compost carefully removed from the fleshy roots, and re-potted in a mixture of equal proportions of peat, chopped sphagnum-moss, and Orchid leaf-soil, with the addition of a little sand and charcoal. They are then placed in a moist atmosphere, having a temperature of 60° to 65° Fahr. by day and 55° at night. They are watered with rain water exclusively, and they produce bright green leaves and an abundance of flowers.

JOURNAL OF THE BRITISH GARDENERS' ASSOCIATION.—In the last issue of the quarterly series of this journal the principal articles include one from Mr. HENRY ED. HEATON, who considers gardeners' grievances, the reputation of gardeners, and other kindred subjects: a letter from "JUNIUS," which is an appeal to the horticultural trade to countenance the Association; several letters from Mr. R. LEWIS CASTLE and others on the conditions of employment at Kew; and an article by "W. W." on gardeners' discounts. With the next issue the journal will commence to appear at monthly intervals.

THE KEW GUILD JOURNAL.—It is always a pleasure to receive the annual journal published by the Kew Guild, for it contains a vast amount of information that, if specially relating to Kewites, is, nevertheless, interesting to all who are engaged in any branch of horticulture. The frontispiece to the present issue is an excellent portrait of Mr. R. IRWIN LYNCH, M.A., Curator of the Botanic Gardens at Cambridge, who left Kew in 1879 to take up the duties of his present position, having filled various responsible posts at Kew during the 12 years he spent in those gardens. Mr. LYNCH'S success at Cambridge, no less than his valuable contributions to botanical and horticultural literature, fully entitle him to receive the honour his fellow Kewites have thus conferred upon him. The list of appointments and retirements shows that Kew-trained men are deservedly sought after to fill some of the most responsible positions at home and abroad. The obituary notices include the names of ten men, all of whom have done useful work, although the lives of some of them were, unfortunately, of short duration. Among the younger men who have been lost through death are W. B. FRENCH, LEO FARMAR, and ALEXANDER AIKMAN. The wages question at Kew is discussed, and strong exception is taken to a statement made in the House of Commons by Sir E. STRACHEY to the effect that the gardeners during their employment at Kew are really apprentices, and that the salaries paid them is intended rather as subsistence money than as wages. The gardeners may have excellent reasons for complaining that the salaries paid to them are inadequate, but it is regrettable that they should have chosen to show their dissatisfaction by voluntarily absenting themselves from the courses of lectures provided in the gardens for their benefit. The policy of throwing away these advantages because they have so far failed to obtain their wishes in another direction appears to us unsound. We understand that these lectures, which were formerly delivered in the evenings, are now to be given during the working day. The letters from old Kew men resident in the Colonies and abroad are full of interest; but in some of them the complaint is made that there, as in England, a gardener's status is not equal to the responsible duties he is called upon to discharge.

MR. GEORGE NICHOLSON, A.L.S., V.M.H., we regret to say, is at present suffering a very serious illness. Mr. NICHOLSON is known personally or by repute to the vast majority of our readers as the former Curator of the Royal Botanic Gardens, Kew, and as author of the indispensable horticultural dictionary which bears his name. He is held in such respect by those who have been privileged to know him intimately, that we are sure our hopes that the illness will eventually be overcome, will find an echo in the minds of all who read these lines.

GARDENERS' CRICKET.—We understand that Mr. and Mrs. HARRY J. VEITCH have again issued invitations to the various committees of the Royal Horticultural Society to visit Burnham Beeches during the coming season for the purpose of engaging in a friendly cricket match.

TREATMENT OF LAWNS.—Messrs. SUTTON & SONS, Reading, have published a new edition of their useful brochure *Lawns*, and every one having the care of a greensward which has to be kept mown should obtain a copy. The little work treats of "Garden Lawns," "Tennis Lawns," "Bowling Greens," "Croquet Grounds," "Putting Greens," "Cricket Grounds," &c. Plans for laying out tennis and croquet lawns are often needed by gardeners, as is shown by enquiries received at this office. The information contained in *Lawns* is the outcome of repeated experience, and, therefore, it is trustworthy. The price of this edition is the same as previous ones, namely, one shilling.

RUBBER AREAS OF DIFFERENT COUNTRIES.—At a meeting held in Mexico City, of Mexican rubber planters, Dr. PEHR OLSSON-SEFFER is stated to have made the following statement in reference to the areas of planted rubber in Mexico and in other countries of the world:—From data at hand I would consider the world's area of rubber plantations to be 355,000 acres, distributed as follows: Mexico, 90,000 acres; Malay Peninsula, 92,000; Ceylon, 85,000; Africa, 30,000; Central America, 14,000; Java, 10,000; India, 8,200; Brazil, 6,000; Venezuela, 6,400; Ecuador, 3,000; Borneo, 2,000; Colombia, 1,800; and West Indies, 1,600.

* **PASTURES.**—The work of Mr. SUTTON on *Permanent and Temporary Pastures* is well known, and a new edition of the popular issue cannot but be welcome to everyone who has to manage grass, whether he is interested in it from the horticultural, i.e., the æsthetic, standpoint, or whether he regards it from the agricultural and economic point of view. The book will, of course, appeal more especially to the latter class of readers; the various grasses that occur in pastures are fully dealt with, and their fodder and other values are fully and plainly set forth. The various chapters on management and manuring of grass land add to the value of the book.

* *Permanent and Temporary Pastures*, by Martin J. Sutton. Popular edition, price 1s. Simpkin, Marshall, Hamilton, Kent & Co.: London. 1908.

A DESERT GARDEN IN EGYPT. We have received a copy of the *Egyptian Gazette* for February 19, containing a popular description by Mrs. IRENE HARVEY of an interesting garden at Al Hayat, Helouan, Egypt. This garden has been constructed by Baron KNOOP, and is remarkable for the fine features it contains, although situated in an arid desert fronting the Great Pyramids, but separated therefrom by many leagues of sand.

CO-OPERATION.—Co-operation among agriculturists has developed in France probably to a greater extent than in any other country. The farmers' organisation is said to possess 8,501,695 members, forming 7,089 societies. As a result of this universal co-operation, agriculturists are able to buy and sell on the most advantageous terms, and have secured cheap transport for their products.

COCOANUT BLEEDING DISEASE IN CEYLON.—Judging from reports in the Ceylon newspapers, this disease is the cause of considerable anxiety amongst the planters. It has shown itself at Kurunegala to such an extent as to have caused almost a panic there. The Government mycologist, Mr. T. PETCH, according to the *Ceylon Independent* of January 29, has succeeded in inoculating a number of healthy Cocoanut trees at Peradeniya with a culture of the spores of the fungus Thielaviopsis ethaceticus, which causes it. The exudations from the diseased tissue are of so gummy or sticky a nature that wind dispersal is out of the question. It is most likely that the disease is conveyed by the Cocoanut gatherers when they climb the trees or by small mammals, like squirrels or polecats, which swarm up the trunks at night. It will probably be best combated by treatment on similar lines to that employed for the Nectria disease. The official report of the mycologist on it was sent in to the Government in December. In the Ceylon Administration Report for 1906—Royal Botanic Gardens (Dr. J. C. WILLIS, director)—Mr. PETCH writes: "The disease is characterised by a flow from minute cracks on the stem of a liquid, which forms rusty-brown or black patches on the exterior. In many cases, especially on old trees, it causes merely a local injury, but on younger trees it may reduce the whole of the interior of the tree to a brown mass of humus. The symptoms have been known for many years, but it is only recently that it has shown signs of becoming a serious disease."

SCHOOL GARDENS.—On Tuesday last a question was put in the House of Commons by Sir FRANCIS CHANNING to the PRESIDENT of the Board of Education, asking if he would "state what is the present number of school gardens provided for elementary, secondary, and evening schools, respectively, in England and Wales; in how many of such school gardens are arrangements made for fruit cultivation as well as for gardening; and what is the number of detached demonstration or experimental fruit plots to which pupils of schools have access." Mr. MCKENNA answered that "the number of public elementary schools in England and Wales notified to the Board for the purpose of the grant for gardening is 1,138, each of which, of course, has ground specially devoted to the purposes of school gardening; but there are in addition a number of schools in which gardening is carried on more as a part of nature study than for the purpose of teaching gardening as such, and the gardens of these schools are not included in that number. Few secondary schools have school gardens intended to teach practical gardening to the scholars, but several schools in England (and one or two in Wales), the curricula of which are regarded by the

Board as having a distinctively agricultural character, have land for outdoor demonstration and experimental work in plant life; and a number of other secondary schools in England possess gardens which are utilised in connection with the biological teaching. The applications for recognition of evening school gardening classes for the current year have not yet all been received, but, assuming that the applications still to be received will correspond with last year, the number will amount to about 190 in England and Wales. It is impossible to say in how many of the elementary and evening school gardens arrangements are made for fruit cultivation, as few counties have any uniformity of practice in this respect, but it is probably about half. In only two of the secondary schools is provision made for the systematic teaching of fruit culture. As far as I am informed, to only one of the detached fruit stations in the country have the pupils of any public elementary, secondary, or evening schools regular access for practical instruction."

Publications Received. *Gardening for Women*, by the Hon. Francis Wolsley, published by Cassell & Co., Ltd.—*Heredity*, by J. Arthur Thomson, published by John Murray.—*The Townsman's Farm*, by "Home Counties," published by Cassell & Co.—*The Insect Book*, by W. Percival Westell, published by John Lane.—*Diet Difficulties, with Notes on Growing Vegetables*, by Mrs. C. W. Earle and Mrs. Hugh Bryan, published by Truslove & Hanson, Ltd.

MARKET GARDENING.

NOTES FROM THE "FRENCH" GARDEN.

We are now cutting Cabbage Lettuces. They have succeeded fairly well, but the weather has been rather too mild for them, and therefore the hearts are less close than they would have been in bright, frosty weather. All the Radishes have been removed from the earlier beds, and the space is now occupied by Lettuces and Carrots. We are completing the planting of the Cos Lettuces on the hot-beds. Our custom is to plant those Cos Lettuces that are put between the cloches—bell glasses—a week or ten days later than those which are put under cloches. The reason for doing this is to enable the plants under the bell-glass to obtain a good start over the others.

On February 15 we sowed seeds of Endive (La Rouennaise) on a brisk hot-bed, and the seedlings will be pricked off into another hot-bed at once. They will subsequently be planted in cold frames, putting 25 plants under each light, or three plants may be put under a bell-glass. This work will be done at the beginning of April. Endives require a considerable amount of artificial heat to get them to germinate satisfactorily during early spring. Experienced cultivators prefer to sow seeds two or three years old rather than new ones, as they believe the plants raised from the older seeds are less liable to run early to seed.

A batch of early Cabbage ("Ox Heart") raised from seeds sown on August 20 and pricked off on October 1 were planted in sheltered beds on November 15. They have withstood the winter well, and the surface soil around them has been stirred with the hoe during the present week. These Cabbages will be fit for consumption at the end of April or the beginning of May.

Melon plants are succeeding well in the hot-beds. They will be planted out permanently in the frames at the end of this present month.

Cauliflowers that were planted behind the first batch of Cos Lettuces, under the cloches, were raised from seeds sown on a hot-bed on February 15. They are planted directly under the cloches. Some growers use plants for this purpose, which they raise from seed sown in September, but by sowing a special batch for the cloches, we obtain a succession to the crop cultivated next to the Carrots in the frames.

It is necessary now to sow a batch of Cauliflowers for cultivation in the open garden, selecting the variety Lenormand and Driancourt. The former variety has a larger habit of growth than the latter, but it does not mature so early. The heads are very large in size, and are usually ready for consumption in August. We do not make a practice of pricking off Cauliflowers that are raised in the spring or summer, as the heads would appear earlier than desired, and the results be unsatisfactory. *Paul Aquatias, Maryland, Essex, March 11.*

FIG. 77.—PASSIFLORA CŒRULEA "CONSTANCE ELLIOTT": FLOWERS WHITE.

Fig. 78.—Passiflora vitifolia: flowers scarlet.

PASSION-FLOWERS AND THEIR CULTIVATION.

Our gardens would be poor indeed without the beautiful natural order of the Passifloraceæ, which, with one exception, P. arborea, are climbing plants. Many of them bear edible fruits, more or less oval in shape and of an olive-green colour; such are those of P. quadrangularis and P. macrocarpa, both large-fruited plants. The species may be divided for garden purposes into three divisions, so far as regards these islands, viz., the hardy species P. cœrulea and P. cœrulea var. Constance Elliott (see fig. 77); secondly, those which succeed in a greenhouse furnished with a heating apparatus for winter use; and, lastly, the hot-house or stove section, as P. edulis, P. kermesina, P. princeps, P. quadrangularis, P. vitifolia (see fig. 78), &c. There are certain essential points in the cultivation of Passion-flowers, the neglect of any of which is sure to result in a more or less flowerless condition of the plants. They are too often grown in much shaded and sparingly ventilated glasshouses, and this is more likely to occur when the plants are grown in borders, and therefore are not easy to remove. I would not advise this mode of growing the plants on account of the difficulty of affording the required rest in the winter season, the weak root system of the plants in general, and lastly the fact that they must endure the treatment afforded the other plants in the house, whether that happens to be suitable or otherwise. Passion-flowers can scarcely receive too much sunshine for good blooming, indeed shade is distinctly deleterious. The hybrid Impératrice Eugénie, if grown in a pot and shifted till it is in one of 10 inches in diameter in its third year, at which age it should flower freely, may be taken out of doors in June and grown against a wall having a due west aspect; in this position the plant will produce flowers the entire summer through. It should here be remarked that this hybrid, and others with large blooms, are not so free in flowering as the smaller-flowered species and hybrids. In all cases the growths of Passion flowers should be kept thinned out at short intervals of time, and the dead and weak growths must be removed during the summer as well as at the winter pruning, thus ensuring the thorough ripening of the remaining shoots. P. Raddiana (kermesina) and P. princeps (racemosa), stove species, are weaker growers than P. cœrulea and its varieties, and require smaller pots and they do not need so much space in which to grow; but they are, under good treatment, decidedly more floriferous than P. cœrulea. This last species is a hardy plant in this country south of the Humber, in the warm south-west of Scotland, the south of Ireland, and in the maritime parts of Wicklow, Down, and about Dublin.

Passion-flowers have been largely inter-crossed, the hardy species above mentioned being often employed as the female parent, as was the case with P. c. racemosa, the product of the cross being a beautiful flower; P. c. kermesina is supposed to be a cross with P. Raddiana; a white form named Constance Elliott, which has the hardiness of the mother species and is equally floriferous, was produced by an unknown cross. The species P. alata ♂ (see fig. 79) and P. racemosa ♀ when crossed, resulted in the fine variety P. amabilis. P. Belottii is supposed to be a cross of P. quadrangularis and P. cœrulea-racemosa; P. Buonapartea is supposed to be a cross between P. quadrangularis and P. alata, and there are many others, of which the parentage may only be surmised in some instances, although in others their origin is duly recorded.

A suitable soil for all the sections of Passion-flowers consists of fertile pasture loam, one half, decayed manure one quarter, moderately hard peat one quarter, and as much sand and crushed bones as the loam requires to afford free passage for the water. The potting should be firm, but a rammer should not be used; and the root system being rather scanty, only a small shift at each repotting is advisable. As aids to growth during the summer, decayed cow dung as a top dressing, and sheep or deer droppings as a liquid manure, are useful. The application of root moisture during the winter should be merely sufficient to prevent the withering and shrivelling of the growths and stems.

Propagation of the plants is easy by means of softwood cuttings with a slight heel of the older wood, and they should be taken when growth has started in the spring. Such cuttings may be

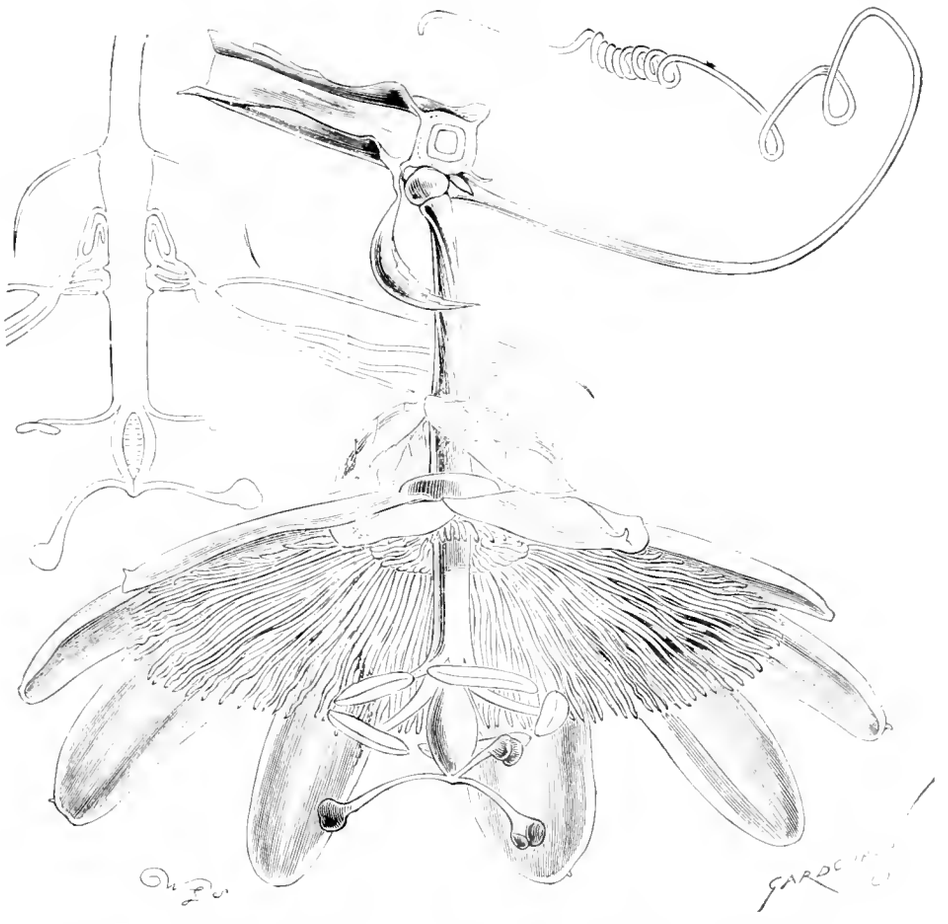

Fig. 79.—Passiflora alata: flowers crimson, with purple rays.

put into a sand bed in the propagating house, covering them with a bell glass or small hand glass. It is advisable to remove the condensed moisture from the inside of the glass every morning in order to avoid damping off. Failing a sand bed pots may be employed, three to five cuttings being placed in sandy soil quite near to the side in each. Cuttings also root quite readily in an ordinary dung bed frame. This last is a good method with varieties and species difficult to propagate from cuttings. *F. M.*

HOME CORRESPONDENCE.

(The Editor does not hold himself responsible for the opinions expressed by his correspondents.)

THE GARDENERS AT KEW.—During a recent conversation with a well-known nurseryman, I was surprised to hear him remark that the gardeners at Kew spend a great part of their time walking about with a pocket lens and a note-book. I am sorry to say he does not stand alone in holding this opinion. Many gardeners and nurserymen, particularly nurserymen, seem to be unreasonably prejudiced against the Kew gardener, regarding him as a theoretical, scientific individual, with little ability or desire for practical work. Allow me, as one who can speak from experience, to correct this erroneous impression. Generally speaking, the work done by the young gardeners at Kew is quite as practical and as rough as that on the average market nursery. Hosing, scrubbing paint, glass, etc., washing and crocking pots, trenching beds and borders, wheeling manure, sweeping, pecking up and gravelling paths, cleaning out tanks, etc., are among their ordinary duties. The hours devoted to work are, with the exception of mid-winter, from 6 a.m. till 6 p.m. Of course, some of them do study more or less, but the majority are simply practical gardeners, following a practical gardener's career, and leave Kew with little better botanical or scientific knowledge than they entered. The gardeners do not grumble or object to their work, but they do protest against being unjustly labelled "theoretical," especially when this false impression acts as a hindrance, and often prevents them obtaining situations which they are quite competent to fill. *C. H. M.*

SEA SAND FOR BOWLING GREENS AND LAWNS.—The recent enquiry leads me to ask why does anyone lay down turf upon sand of any kind? I cannot see how a good root action is to be secured in the case of turves averaging not more than 2 to 3 inches in thickness and laid upon sand. I have seen many such lawns, but never one that could be called a success. Even during the abnormally wet season of last year, I witnessed several greens and lawns that were in an unsatisfactory condition, and these were laid upon sand. During hot weather there is no moisture in the sand, but this material being a hungry, absorbent element, soon causes the grass to turn a bad colour. I have used sea sand for potting purposes, for which it answers just as well as fresh water sand. I am about to prepare some new greens in connection with our new public park, and I have millions of tons of sea sand at my command, but it will be the very last thing I shall use. Some few years ago, whilst head gardener in Belfast, I made a large lawn, and the turves were laid on soil. At the same time a similar lawn was made by a neighbour, but he used sand from the shore, with the result that his grass had afterwards to be kept continually watered, whilst mine never required any water other than the rain. My friend declared afterwards that he would never lay turf upon sand again. *Victor H. Lucas, Gardener to Borough Council, Barrow-in-Furness.*

JUDGING VEGETABLES BY POINTS.—I consider the only proper and just method of judging vegetables is by points, and I see no reason why small collections as well as large ones should not be judged in this manner. The greatest possible care should be exercised with respect to the relative merits of the various kinds of vegetables, but no code, however well it may be compiled, can answer for all the seasons of the year. The more difficult it is to produce a certain vegetable in a certain season the higher should be the number of points awarded to it. I do not agree with the placing of all vegetables on an equal merit when pointing for a prize. For instance, an exhibitor may find that at the last moment the samples of one of his choicest vegetables, say Celery, Carrots, or Leeks, are not up to the highest exhibition standard, and that he will probably lose two or three points should he include them in his exhibit. He may, however, have perfect samples of Parsnips, Marrow, Cucumbers, or even Cabbage, and the judges can do no less than award them the maximum number of points if they consider them worthy. This is equivalent to awarding the same number of points to three perfect bunches of Black Alicante Grapes as to three equally perfectly finished bunches of Muscats. In all cases where judging is done by points, the numbers should be affixed to the competitors' cards both for the satisfaction of the exhibitor and for the information of the public. Good judges know the relative value of each kind of vegetable exhibited, the season at which they are exhibited, and the quality of the varieties staged. If a judge does not possess sufficient ability to adjudicate in a vegetable competition without the aid of a code by the wording of which he is bound, no amount of rules, however well they may be framed, will enable him to arrive at a fair decision. *E. Beckett.*

THE GRAFTING OF CLEMATIS.—In the issue of March 14, Mr. H. Evans questions the advisability of grafting hybrid Clematis. I did not touch on this point, because in my article (see p. 149) the remarks were confined to the process of grafting. It is true that failures are attributed to the fact that plants are not cultivated on their own roots, but I should like to ask, "Are plants that have once become established ever found to be other than on their own roots?" As far as I have been able to judge, every Clematis that is given a good soil of light texture will very quickly produce an abundance of roots above the graft. If the horizontal cut, as I recommended, is applied, the plants in their early stage become partly dependent on the roots they will form and eventually almost entirely so, because they will develop much more quickly than those of the stock (C. vitalba). I have noticed the stems of plants die off near the surface of the ground and shortly afterwards other shoots appear from below the surface; in such cases it seems improbable that grafting was to blame, as part of the plant above the union must have been left intact. Of course, these plants had formed roots of their own, but I am assuming that the seat of decay is supposed to be at the union of the stock and scion. I am not able to say whether these sudden failures are confined solely to plants that have been grafted or not. I see nothing to hinder one from raising any variety from layers, especially if a little aid is given in the form of peeling off a little of the bark from the stem which is to be pegged beneath the soil. Many sorts of Clematis can be propagated by means of cuttings, but to my mind neither of these latter methods are as sure to be successful as grafting; that is, where quantities of various hybrids are required. *W. B. Little.*

THE SPECIES OF PHORMIUM.—At the late Lord Battersea's garden at Overstrand, in Norfolk, we had a large number of these plants, the varieties being P. tenax, "Powerscourt variety," and P. variegata and Messrs. Veitch's variegated form. Particularly in regard to the latter two varieties, the position was very much on the dry side. They were planted in pockets under an avenue of trees in a compost of loam, leaf-soil, and peat. At the time of my employment there, the plants had become specimens some 7 to 8 feet in height, and had flowered very freely each year for five years. The year 1906 was very dry, yet few waterings were given them, and they all flowered at that season. In the early spring, we shifted two large clumps and placed them in pockets in an island in the water garden. The walls of the pond being of cement, and the bottom of the same material, the conditions were the same as planting in a border. Only occasional waterings were given them, yet they throve and are still thriving. The other varieties were given similar positions, and all succeeded well. They were never given any protection during winter, and yet remained uninjured. When Mr. Mallett visited the place he remarked how well they were doing. Here at Sutton Place, some plants of P. Cookianum were planted in a swamp, and very unhappy they looked. They have, however, in the course of some alterations, been transferred to a much drier position, and are at this early stage showing signs of improvement. *Donald Watson, Sutton Place Gardens, Guildford.*

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 17.—A beautiful display of flowers was seen at the meeting held on this date. The Orchids were good, especially the groups shown by Major HOLFORD and J. BRADSHAW, Esq. Forced trees and shrubs formed a considerable portion of the exhibition; there were also many good collections of hardy spring-flowering plants; of florists' flowers, including Cyclamen and Cinerarias, Roses, and bulbous flowers.

The FLORAL COMMITTEE made no award to a new plant, nor did the NARCISSUS or FRUIT AND VEGETABLE COMMITTEES have any subject worthy of award before them.

The ORCHID COMMITTEE'S awards to novelties included two First-Class Certificates, four Awards of Merit, and two Botanical Certificates.

At the afternoon meeting of the Fellows, 61 names were accepted for membership, and a lecture on "Beautiful Flowering Trees and Shrubs" was delivered by Mr. George Gordon, V.M.H.

Floral Committee

Present: W. Marshall, Esq. (chairman), and Messrs. Chas. T. Druery, Jno. Green, T. W. Turner, G. Reuthe, C. R. Fielder, Jas. Hudson, J. W. Barr, E. Bowles, W. Howe, J. Jennings, F. Page Roberts, Jas. Douglas, Chas. Dixon, Chas. E. Pearson, R. C. Notcutt, H. J. Cutbush, W. Cuthbertson, W. P. Thomson, Arthur Turner, E. H. Jenkins, W. J. James, Geo. Paul, Chas. E. Shea, J. F. McLeod, C. Blick, and R. Hooper Pearson.

A group of much excellence was exhibited by E. A. HAMBRO, Esq., Hayes Place, Kent (gr. Mr. J. Grandfield). The subjects were mostly showy-flowered plants, but there were many choice Alpine species. We noticed a magnificently-flowered pan of Saxifraga Boydii alba, and an almost equally meritorious plant of S. Boydii. The majority of the group was made up of Primulas, Anemones, Scillas, Narcissi, and other bulbous flowers, with flowering shrubs interspersed, the whole being arranged with artistic merit. (Silver-Gilt Banksian Medal.)

A pleasing display of Clematis and other greenhouse flowering plants was presented by Messrs. H. B. MAY & SONS, Upper Edmonton. There were many choice Ferns, including some of the newer varieties of Nephrolepis exaltata, intermingled in the group. Primula × kewensis appeared to advantage against the greenery of Azaleas and other plants. Pelargonium Clorinda was included in the exhibit, which also embraced many well-flowered plants of Cyclamen latifolium. Notable varieties of Clematis were Lord Wolseley, Mrs. Quilter, Lord Londonderry, and Nellie Moser. (Silver-Gilt Banksian Medal.)

Messrs. HUGH LOW & Co., Bush Hill Park, Enfield, staged one of their usual displays of flowering plants of greenhouse species, with vases of Carnations. There were many of the choicer varieties of Azalea indica; Franciscea calycina, 25 varieties of Acacias, Lachenalias, Gerbera Jamesonii, &c. (Silver Flora Medal.)

Messrs. CANNELL & SONS, Swanley, Kent, provided a scene of brilliant colouring in their vases of Zonal Pelargoniums, in varieties representing most of the choicest kinds in cultivation. They also displayed "pips" of their strain of Primula sinensis. (Silver Banksian Medal.)

The space under the wall opposite the entrance was again filled with groups of forced trees and shrubs. Messrs. JAMES VEITCH & SONS, Ltd., King's Road, Chelsea, staged an effective group, in which a prominent position was afforded plants of the handsome-leafed Vitis Henryi; there was also a number of finely-flowered Lilacs, among which were the varieties President Grevy, Marie Legraye, Madame Lemoine, Souvenir de Louis Spath, the bright-red-

dish Michael Buchner; well-bloomed trees of Wistaria sinensis, Cytisus Laburnum vulgare Vossii, having longer and more lax and slender panicles than the type; Cerasus serrulata, a fine double-flowered white Cherry; Pyrus Malus Scheideckeri, Forsythia intermedia, a cross between F. suspensa and F. viridissima, of a more compact habit of growth than either parent; Kerria japonica fl. pl.; Staphylea colchica; many varieties of Rhododendrons, including Early Gem Handsworth, Early Red, Christmas Cheer, &c. Messrs. Veitch also staged a number of greenhouse flowering plants on one of the tables. We noticed many interesting and useful spring-flowering subjects, such as Strelitzia Kegmæ, Camellia reticulata, Streptosolen Jamesonii, Azalea amœna "Hexe," Primula × kewensis, and at one end of the exhibit tall plants of Rhododendron Veitchianum and R. Forsterianum. A batch of the florists' Cyclamen completed the display. (Gold Medal.)

Messrs. R. & G. Cuthbert, nurserymen, Southgate, Middlesex, contributed a large group consisting of many plants of finely-flowered Azalea, varieties of sinensis having rich and vivid tints. The more striking varieties were Consul Pecher, orange and red; Mrs. A. E. Endtz, clear yellow, with slight spotting on the upper segments; Florodora, of a rosy orange tint; and Elizabeth, rosy red. There were also Lilacs in variety, mostly in standard shape; Magnolia Soulangeana nigra, and species of Pyrus. (Silver-Gilt Banksian Medal.)

Mr. L. R. Russell, Richmond Nurseries, Richmond, Surrey, showed a group of forced shrubs, consisting of Lilacs, mostly white-flowered, Azalea mollis, Clematis indivisa lobata, Prunus triloba, &c. (Silver Flora Medal.)

A pretty group of forced shrubs, principally Cherries and Peaches, was shown by Messrs. W. Paul & Son, Waltham Cross, Herts. The exhibit was staged in the corner of the Hall near the annexé, a number of tall Dracænas being utilised as a background. The yellow Banksian Rose was included in the display, also a plant of the beautiful single yellow-flowered species, Rosa Hugonis. (Silver Banksian Medal.)

Messrs. Sutton & Sons, Reading, exhibited a number of plants of the florists' Cineraria, having flowers of pink and blue colours with intermediate shades. The plants were compact, and had healthy foliage, above which the spreading inflorescences appeared to advantage. The flowers were of the most approved form, and the trusses were compact, yet sufficiently spreading to display themselves. Some were of a deep shade of blue, and these were especially pleasing. At one end of the exhibit was a number of plants of the star or Stellata type, with inflorescences no taller than those of the florist's type. Messrs. Sutton also showed a number of hybrid Freezias.

Exhibits of Carnations were presented by Mr. H. Burnett, Guernsey (Silver Flora Medal); and Mr. W. H. Page, Tanglay Nurseries, Hampton; Mr. Page also exhibited large-flowered spécies of Lilium. (Silver Banksian Medal.)

Mrs. Barton, Birtley, Bramley, Guildford (gr. Mr. Streeter), showed very large plants of Cinerarias. (Bronze Flora Medal.)

Messrs. Jarman & Co., Chard, exhibited tall, lax-flowering Cinerarias with conv lute florets. From the habit of the plants, they appeared to have been derived from some tall-growing species crossed with the florists' type.

A collection of Cyclamen latifolium was exhibited by the St. George's Nursery Co., Harlington, Middlesex. This large exhibit embraced flowers of numerous shades, but the plants, although well grown, did not impress us as being up to the high standard of excellence seen from the same nursery in former years. (Bronze Flora Medal.)

A beautiful display of Roses was again presented by Mr. Geo. Mount, Canterbury, Kent. The new variety Joseph Lowe was given prominence, and found many admirers. There were also fresh and large blooms of Mrs. W. J. Grant, Richmond, Frau Karl Druschki, and Liberty. (Silver Flora Medal.)

Mr. Robert Sydenham, Tenby Street, Birmingham, displayed, as at the last meeting, vases of bulbous flowers, grown in moss fibre. (Bronze Banksian Medal.)

Messrs. W. Cutbush & Son, Highgate, London, N., showed an exhibit of hardy flowers, and on an opposite table, a large array of flowering shrubs. The Alpine and other hardy flowers were arranged in an imitation rockery, and the subjects were cleverly disposed. We noticed a fine form of Incarvillea Delavayi named grandiflora. There were also the usual spring-flowering subjects, such as Scillas, Crocuses, Hepaticas, Primulas, Irises, &c. The shrubs included Magnolias, Acacias, Rhododendrons, Ledum latifolium, Ericas, Azaleas, and many other species. (Silver-Gilt Banksian Medal.)

Messrs. Barr & Sons, King Street, Covent Garden, London, displayed flowers of Narcissi, all of which had been grown under glass. Adjoining the Daffodils, the same firm staged a collection of hardy flowers, including many Alpine and rock-garden species. Boxes of Crocuses were very showy; there were also Anemones, Fritillarias, Scillas, Hellebores, Primulas, and other spring flowers in great variety. (Silver Banksian Medal.)

Messrs. John Peed & Son, West Norwood, Surrey, showed numerous hardy flowers, an assortment of small Cactaceous plants, and a batch of well-flowered plants of Primula obconica. Some fine spikes of Lachenalia Nelsonii were displayed in vases, the remainder of the exhibit being principally of rare and interesting species of Saxifragas, Primulas, and similar plants.

A small, but interesting exhibit of dwarf hardy plants was shown by Messrs. Heath & Son, Cheltenham. We noticed a finely-flowered pan of Saxifraga oppositifolia, and another of Primula frondosa in Messrs. Heath's collection.

A display of hardy plants was shown by the Guildford Hardy Plant Nursery, Guildford, Surrey. Many hardy Heaths were shown in this group, the species including Erica carnea, E. mediterranea hybrida, E. cupresa, &c. A pan of Pulmonaria saccharata was an attractive feature. There were also many rare Primulas, the dwarf-flowered Doronicum Columnæ, Iris reticulata, &c.

Messrs. T. S. Ware, Ltd., Ware's Nursery, Feltham, Middlesex, showed an exhibit of hardy flowers, many of which were suitable for the rock garden. A prominent position was afforded a group of Primula obconica of a larger flowered strain than the type. (Bronze Flora Medal.)

Messrs. Joseph Cheal & Sons, Crawley, Sussex, showed a few pans of Alpine plants, with dwarf-habited Conifers and shrubs suitable for planting in the rock-garden.

A realistic piece of rock-gardening was shown by Mr. H. C. Pulham, Elsenham, Essex, the stones being admirably disposed and the spaces planted with suitable subjects.

Mr. G. Reuthe, Hardy Plant Nursery, Keston, Kent, had numerous species of Crocus, Ericas, Anemones, Fritillarias, Hepaticas, Saxifragas, Primulas, &c., with showy trusses of Rhododendron arboreum, R. barbatum, and other early-flowering species. (Bronze Flora Medal.)

Messrs. Geo. Jackman & Son, Woking, Surrey, exhibited Alpine and other hardy flowers, amongst which we noticed a spike of the beautiful Watsonia Ardernei. There were also Scillas, Fritillarias, Tulips, Cyclamen, Anemones, and many other spring-flowering subjects.

The Misses E. & M. Kipping, Hutton, Essex, showed a small collection of Alpine plants in flower, amongst which were many pleasing varieties of Primrose, including red and other coloured varieties.

Miss Alice M. Smith, Barnham, Bognor, also showed coloured Primroses and other spring flowers.

Narcissus Committee.

Present: H. B. May, Esq. (Chairman); and Messrs. A. Kingsmill, G. H. Engleheart, J. T. Bennett Poe, Joseph Jacob, Jas. Walker, Alex. M. Wilson, W. T. Ware, R. W. Wallace, H. A. Denison, F. Herbert Chapman, P. Rudolph Barr, and C. T. Digby.

There were no novelties before this committee, and only one group was staged. This was exhibited by Messrs. Barr & Sons, King Street, Covent Garden, London, and was composed entirely of forced flowers. In this connection it is interesting to record that such diverse sections as incomparabilis, Leedsi, Ajax, Barrii, Johnstoni, Poeticus, and odorus were represented. Among the many varieties staged, the choicer were the double Sulphur Phœnix, Monarch, Victoria, Queen of Spain, White Lady, and Barrii conspicuus. (Silver Banksian Medal.)

Orchid Committee.

Present: J. Gurney Fowler, Esq. (in the chair), and Messrs. Jas. O'Brien (hon. sec.), Harry J. Veitch, De B. Crawshay, W. Boxall, R. G. Thwaites, F. Sander, H. G. Alexander, J. Cypher, F. M. Ogilvie, J. Forster Alcock, W. Cobb, J. Charlesworth, W. P. Bound, A. Dye, W. H. White, H. A. Tracy, H. Ballantine, Gurney Wilson, W. Bolton, R. Brooman-White, C. J. Lucas, A. A. McBean, and Stuart Low.

Major G. L. Holford, C.I.E., C.V.O., Westonbirt (gr. Mr. Alexander), was awarded a Silver-Gilt Flora Medal for a fine group composed of specimen plants of fine varieties. Among the best in the group were the large-flowered, lilac-tinted Odontoglossum crispum Rosemary, which had already secured an award; the equally fine O. c. Egret, and O. c. Westonbirt variety, and another pretty form with blotches on the sepals, the plant bearing four spikes. O. Andersonianum, Westonbirt variety, was a fine form heavily marked with claret colour. Dendrobium Magda, D. Melpomene, and D. Perseus were represented by fine specimens, the D. Perseus aureum being one of the best of the yellow species. Other fine things were Lælio-Cattleya Earl Grey, rose-purple with claret lip; L.-C. Dorothy, a pretty, new, yellow hybrid; Brasso-Cattleya Digbyan-Mendelii, a pretty blush-white form; B. C. Madame Hye; the neat little Sophro-Lælio-Cattleya Danæ (Harrisoniæ × læta Orpetiana), and others. (See Awards.)

J. Bradshaw, Esq., The Grange, Southgate (gr. Mr. G. G. Whitelegge), was awarded a Silver-Gilt Flora Medal for a very extensive and fine group, the centre of which was filled with white-flowered varieties of Cattleya Trianæ, the various forms bearing together, 60 blooms. C. T. Esmerelda had fine white flowers with a slight pink tint on the lip, C. T. alba, and C. T. a. "Mrs. Edward Sondheim" were wholly pure white; C. T. Prima Donna was of fine form, white, with a small purple feather on the lip; C. T. Thetis, silver-white, with lilac-tinted lip, and other distinct white forms were included. Of the coloured varieties, C. T. Exquisite, C. T. Endymion, and C. T. tricolor were magnificent varieties of the true original form. There were good forms of Lycaste Skinneri, both coloured and white, 19 blooms of the pure white appearing; also L. Balliæ, with reddish-crimson flowers; a very good selection of Odontoglossums, &c.

H. S. Goodson, Esq., Fairlawn, Putney (gr. Mr. G. E. Day), was voted a Silver Flora Medal for a pretty group, in which were the handsomely-blotched Odontoglossum crispum Lily Bourdas, which has greatly improved since it obtained an Award of Merit last year; a good selection of other varieties of O. crispum, O. Hallio-crispum, O. Vuylstekei, and several other pretty hybrids, two plants of the white and rose Miltonia Phalænopsis, Angræcum Sanderianum with three spikes, a magnificent yellow and claret-coloured form of Odontoglossum Wiganianum, &c.

Messrs. J. Cypher & Sons, Cheltenham, secured a Silver Flora Medal for an effective group of good varieties of Dendrobium, Odontoglossum crispum, and other Odontoglossums, including a showily-blotched form of O. ardentissimum, O. blandum, and others. Among the Cypripediums were C. Beekmannii, C. aureum Hyeanum, and a fine form of C. Mons. de Curte. The centre was of bright scarlet Sophronitis grandiflora, and Epiphronitis Veitchii.

Messrs. J. & A. A. McBean, Cooksbridge, were awarded a Silver Flora Medal for a fine group of Odontoglossums grown and flowered in the excellent manner usual with them. The group contained a selection of the typical white and rose-tinted type, and a good number of handsome, blotched kinds, including O. c. King Richard, O. c. Xanthotes, O. c. Oakfield Sunrise, and some unnamed varieties. One pretty specimen bore a branched spike of 52 flowers.

Mr. A. W. Jensen, Lindfield, Sussex, was awarded a Silver Flora Medal for a group of extraordinarily fine forms of Cattleya Schroderæ from his recent importation, the flowers being large and of fine form, very fragrant, and varying from blush-white with orange throat, to rose

with purple markings on the labellum. Some varieties of Odontoglossum crispum were shown, especially one handsomely-blotched form.

Messrs. HUGH LOW & Co., Enfield, were awarded a Silver Flora Medal for a good group, in which Cattleya Schroderæ Enfieldiensis was a very fine rose form with violet-purple lip; C. Trianæ plumosa, a very handsome flower; and a blush-white petalled C. Percivaliana, with very dark lip, a distinct form. Among the Cypripediums, C. insigne, E. J. Seymour, C. i. McNabiana, and C. × Mrs. Wm. Mostyn were the best.

F. MENTEITH OGILVIE, Esq., The Shrubbery, Oxford (gr. Mr. Balmforth), staged a pretty group of well-grown Odontoglossum crispum, O. triumphans, O. Rolfeæ, O. Adrianæ, O. Wilckeanum, and others. Also a very fine variety of Cypripedium Bridger grandiflorum, together with its parents, C. Argus Moensii and C. Godseffianum; and other Cypripediums. (Silver Banksian Medal.)

Messrs. SANDER & SONS, St. Albans, staged an interesting group which included the rare blush-white Lælio-Cattleya Kerchoviæ, the pretty Odontioda Lairessiæ, and Odontoglossum Lairessiæ, Epidendrum Wallisii, and hybrids of it; some distinct forms of Cattleya Manæi and C. Schröderæ, Promenæa citrina, Cœlogyne Lawrenceana, Cypripedium Rothschildianum, and other Cypripediums; two forms of Lælio-Cattleya luminosa, the rose-coloured Cynorchis × kewensis, the white form of Epidendrum evectum, and several pretty species of Ophrys. (Silver Banksian Medal.)

Messrs. MOORE, LTD., Rawdon, Leeds, staged an interesting group in which were the singular and rare Dendrobium macrophyllum, with large greenish flowers spotted with purple and strongly hairy on the reverse side; D. fusiforme (see Awards), D. nobile virginale, and other varieties, the finest of which was D. Wiganiæ album; good Cattleya Schröderæ, &c. (Silver Banksian Medal.)

Messrs. HEATH & SON, Cheltenham, showed a group of Dendrobium Wardianum, D. nobile varieties, Epiphronitis Veitchii, Cœlogyne cristata alba, Cypripediums, &c.

Mons MERTENS, Mont St. Amand, Ghent, showed a small group of hybrid Odontoglossums and Cypripediums.

Sir JEREMIAH COLMAN, Bart., Gatton Park, Reigate (gr. Mr. W. P. Bound), staged an interesting selection of hybrid Dendrobiums, including nine very distinct and handsome forms of D. Thwaitesiæ, all raised from one lot of seed. Also D. Mrs. Alfred Rogers, a pretty light hybrid, and D. Rolfeæ, raised by seeds from D. Linawianum ×, and a plant of the singular Epidiacrum Colmanii (E. ciliare × D. bicornutum), with white flowers, the singular labellum having the side lobes fringed and the middle ones linear.

DE B. CRAWSHAY, Esq., Rosefield, Sevenoaks (gr Mr. Stables), showed three interesting and pretty hybrid Odontoglossums raised at Rosefield, viz., O. Waltoniense var. (Kegeljani × crispum, spotted variety); O. Carmen (crispum × Crawshayanum), and O. Electra (Andersonianum × triumphans).

Messrs. CHARLESWORTH & Co., Heaton, Bradford, showed a small group in which there were very fine specimens of Miltonia Warscewiczii, Odontioda Heatonensis, with elegant reddish-rose spotted flowers, the clear white Odontoglossum ardentissimum xanthotis, a fine flower with chrome-yellow markings on the lip, O. amabile, and others. (See Awards.)

FIRST-CLASS CERTIFICATES.

Vanda suavis pallida, from Mons. THEODORE PAUWELS, Ghent. A very fine albino with white flowers, the segments marked with pale green. It is probably identical with V. suavis Sanderæ.

Cattleya Suzanne Hye de Crom (Mossiæ Wageneri × Gaskelliana alba), from Mons. JULES HYE DE CROM, Coupure, Ghent (gr. Mr. Coen). Flowers large, pure white, with yellow disc to the lip. M. HYE DE CROM showed a quantity of cut flowers at the last meeting, and now sent a plant in bloom.

AWARD OF MERIT.

Cattleya Enid, Westonbirt variety (Warscewiczii × Mossiæ), from Major G. L. HOLFORD, C.I.E., C.V.O. (gr. Mr. Alexander). A noble variety with large rosy-mauve coloured flowers, the broad-fringed lip being ruby-crimson with a lilac margin.

Lælio-Cattleya luminosa, Westonbirt variety (L. tenebrosa × C. Dowiana aurea), from Major G. L. HOLFORD. The finest form of luminosa. The very large flowers had Indian yellow sepals and petals tinged with red, and very large claret-crimson lip.

Odontoglossum Gladys (O. cirrhosum × O. Harryanum), from Messrs. CHARLESWORTH & Co. An elegant hybrid with greenish-white sepals and petals blotched with dark purple. In form like O. elegans, but of larger size.

Lælio-Cattleya Elinor (L. Coronet × C. Schröderæ), from Messrs. CHARLESWORTH & Co. A very fine hybrid with the deep orange colour of L. Coronet (L. harpophylla × C. cinnabarina) on flowers of good size and shape.

BOTANICAL CERTIFICATE.

Pleione pogonioides, from Messrs. JAS. VEITCH & SONS, Royal Exotic Nursery, King's Road, Chelsea. A pretty dwarf species with rose-coloured flowers imported by Messrs. VEITCH from China.

Dendrobium fusiforme, from Messrs. MOORE, LTD., Rawdon, Leeds. A rare Australian species with fusiform pseudo-bulbs bearing three or four leaves on the upper part. The inflorescence bore many ivory-white flowers, with some purple markings on the lip. Illustrated in the *Gardeners' Chronicle*, May 25, 1907, p. 337.

CULTURAL COMMENDATION.

To Mr. H. G. Alexander, Orchid grower to Major G. L. HOLFORD, C.I.E., C.V.O., for Odontoglossum Adrianæ, var. Lady Wantage, in a 5-inch pot, and bearing an inflorescence 4 feet 6 inches long, with 13 branches, having a total of over 100 flowers; also for Cattleya Enid magnifica, Westonbirt variety, with a grand inflorescence of six flowers. To Mr. W. H. White, Orchid grower to Sir TREVOR LAWRENCE, Bart., for Brasso-Cattleya Lindleyana, with over 50 flowers.

Fruit and Vegetable Committee.

Present: Owen Thomas, Esq. (Chairman); and Messrs. W. Bates, G. Woodward, C. O. Walter, H. Markham, A. Dean, H. Parr, E. Beckett, G. Kelt, J. Davis, W. H. Divers, J. Vert, J. McIndoe, C. Foster, G. Wythes, C. G. A. Nix, H. Somers Rivers, and W. Poupart.

The chief exhibit before the committee was a collection of several varieties of Oranges, sweet and bitter, oval and round, and a Lemon. The fruits generally were large, but most of them had very thick skins. Those tasted by the committee were sweet and of excellent flavour. They were grown in Cyprus on standard trees, and were exhibited by Mr. ANSELL, of that island. (Silver Gilt Knightian Medal.)

Messrs. G. BUNYARD & SONS, Maidstone, sent for comparison by tasting with Nova Scotian Apples, 13 varieties of home-grown Apples, including Adam's Pearmain, Lane's Prince Albert, Striped Beefin, Wagener, Sturmer Pippin, Lord Hindlip, Lord Burghley, King of Tompkins' County, Beauty of Kent, Newton Wonder, Belle Tontoise, and others. The best flavoured fruits were those of Lord Hindlip, Lord Burghley, Wagener, and Newton Wonder. From the Nova Scotia Government came Baldwin, Nonpareil, Golden Russet, Starke, Fallwater, and King of Tompkins' County. None of these possessed much flavour.

Mr. A. DEAN, Kingston, Surrey, sent English fruits of Bramley's Seedling and Bismarck, and imported fruits of Fallwater and Newtown Pippin. The latter proved to have been frosted. The Committee, after tasting from every dish, decided that the English Apples were the better flavoured, and most crisp and juicy.

MELBOURNE (DERBYSHIRE) AND DISTRICT FRUIT GROWERS'.

MARCH 6.—This association was formed on the above date, Mr. W. H. Perry being appointed the secretary. A resolution was passed that the Board of Agriculture be asked to grant compensation for Gooseberry bushes destroyed under the new Act.

MARKETS.

COVENT GARDEN, March 18.

[We cannot accept any responsibility for the subjoined reports. They are furnished to us regularly every Wednesday, by the kindness of several of the principal salesmen, who are responsible for the quotations. It must be remembered that these quotations do not represent the prices on any particular day, but only the general averages for the week preceding the date of our report. The prices depend upon the quality of the samples, the way in which they are packed, the supply in the market, and the demand, and they may fluctuate, not only from day to day, but occasionally several times in one day.—ED.]

Remarks.—Large quantities of Oranges have been received from Valencia and Denia, and these fruits are much cheaper, with the exception of selected samples. The prices of fruit from Cape Colony remain about the same, but Plums are much dearer, especially fruits of the Kelsey variety. A few Mangos from Jamaica have arrived, and they have realised high prices. Spanish and Giant Asparagus are also in the market. The supply of Madeira Beans has been much smaller during the past week, and consequently they are dearer, especially as their quality is very good. There have been some fine samples of Strawberries sold this week. *P. L., Covent Garden, March 18, 1908.*

Remarks.—Business is firmer, but consignments are lighter, consequently prices are higher. *E. J. Newborn, Covent Garden and St. Pancras, March 19, 1908.*

COVENT GARDEN FLOWER MARKET.

The salesmen complain of dull trade during the past week, and growers report that there has been a great falling off in country orders. Business in cut flowers is very dull, there being but little sale for Liliums, Callas, and other good white flowers, which are generally in demand. West-end florists complain that there is a great falling off in business compared with former years.

Cut Flowers.

Carnations are very prominent, best quality flowers of Britannia, White Perfection, and all other leading varieties are plentiful at a late hour in the morning, and this is a good indication of the demand. "Malmaisons" may not be so profitable to the grower, as they produce fewer flowers compared with the American sorts, yet I find that best blooms make 12s. per dozen, and their prices have occasionally been 18s. per dozen blooms. Marmion makes about 15s. per dozen blooms, and always sells readily; blooms of Mrs. H. Burnett cannot be obtained except quite early in the mornings. Roses are now abundant and of the best quality. Mrs. J. Laing, Caroline Testout, Kaiserin Augusta Victoria, Richmond, Catherine Mermet, and Niphetos are all prominent. Best blooms of Madame Chatenay are cleared early. Sweet Peas are very good, especially white flowers, but at present there is little demand for them, and they lack perfume. Gardenias are more plentiful, and much larger supplies may be expected. Daffodils continue to be over-plentiful, but the best quality blooms are likely to become scarcer. Callas are abundant, and many are sold at very low prices. Liliums vary much both in quality and in price. Imported flowers are abundant. The Mimosa (Acacia) is now nearly over. Violets are remarkably good both home-grown and imported supplies.

Pot Plants.

Cinerarias are now a leading feature and are remarkably good in quality, but the cold weather has militated against their sale. Ericas consist chiefly of E. persoluta alba and E. Wilmoreana, which are both remarkably well flowered. Supplies of Azaleas are holding out well, but the flowers of some are rather far advanced, and these have to be cleared at low prices. Spiræas are very good. I noticed plants of the pink variety of S. japonica at Messrs. T. Rochford and Son's establishment this morning; they were sold for about 3s. 6d. each. Genistas are abundant and well flowered, Marguerites are also good. Solanums are now over for the season. Hyacinths, Tulips, Daffodils, Cyclamen, Mignonette, Boronias, and Acacias are all good. Of the last-named A. ovata is one of the prettiest. A few well-flowered plants of various deciduous shrubs are seen, but there seems to be little demand for them. In flower-roots, Primroses, Pansies, Polyanthus, Daisies, and Arabis are well flowered. All other hardy roots are plentiful, but the cold weather has been much against the trade for them. Rhododendrons in bud, Conifers, and other evergreens; Roses, climbers, &c., are all procurable. *A. H., Covent Garden, Wednesday, March 18, 1908.*

SCHEDULES RECEIVED.

Royal Ulster Agricultural Society's Flower Show, to be held at Balmoral, Belfast, on Thursday and Friday, July 23, 24, 1908.

Midland Carnation and Picotee Society's eighteenth annual exhibition, to be held on August 6, 7, 1908 (provisional).

Tonbridge Gardeners' and Amateurs' Society's Chrysanthemum and Fruit Show, to be held on Wednesday and Thursday, November 11, 12, 1908, in the Public Drill Halls, Tonbridge.

Chester Paxton Society's Fruit and Chrysanthemum Exhibition, to be held on November 11, 12, 1908, in the Town Hall, Chester.

CATALOGUES RECEIVED.

E. P. Dixon & Sons, Ltd., Hull Farm seeds.

Thomas Green & Son, Ltd., Smithfield Ironworks, Leeds —Lawn mowers and other garden requisites.

Ransomes, Sims & Jefferies, Ltd., Orwell Works, Ipswich —Lawn mowers.

Barr & Sons, King Street, Covent Garden, London—Hardy Perennials, Alpines, &c; Seeds.

James Dewsnap, Ltd., 10, St. James Street, Sheffield—Floral garden baskets.

ENQUIRIES AND REPLIES.

A Scottish Garden.—I have just taken a small "shooting" in Ayrshire, Scotland. The garden is about 1,100 feet above the sea, and is 40 yards by 25 yards. It is on the side of a small hill sheltered by woods, facing about S.S.E. or south. The soil is a dark, loamy, peaty earth, and though on the slope of a hill it is too damp even for Potatos to do well in. I am having it drained. I have a good deal of cow dung for manure. Will this suffice or should I add a chemical manure? If so, what kind? What household vegetables would you suggest planting, and what varieties of each kind? I shall want a supply of vegetables from August 1 to October 30. What would be the most satisfactory flowers to plant for cutting for house use? *Naval Officer.*

———You will have to proceed cautiously, as the nature of the soil, degree of exposure, and climate each have to be studied at first hand. The cow manure, if not fresh when used, will be excellent, and you might supplement it with ½-cwt. of superphosphate of lime (probable cost 2s. 6d.), 14 lbs. sulphate of ammonia (2s.), and 14 lbs. Bentley's slug powder. Grow enough Potatos for a supply during August, and perhaps half of September, purchasing field-grown tubers which will cost about 5s. per cwt., for the rest of the period. The varieties Southern Queen and Duke of York may suit your soil, and you will require two or three stones of seed for planting. Apply a layer 1 inch thick of rotted dung, and a mere sprinkling of superphosphate. Peas will require more space than any other vegetable, but the space can be economised by arranging for rows of other vegetables to be grown between the Peas. Apply a 2-inch layer of dung and dig the ground deeply. Sow seeds at the end of March, in the second week of April, first and third week of May, and first week of June, the last sowing to be the largest. Select Sharpe's Queen, using three quarts of seed. Of Beans, sow 1 pint of Green Windsor at the beginning of April. Of Beet, the Turnip-rooted, 1 ounce in mid April. Cabbage, purchase plants to set out in mid March, sow seeds same time to plant at the beginning of June—choose Vanack, ½-ounce. Dress the ground with 4 inches deep of manure, and with superphosphate later. For Carrots, select the Guerande variety, 1 ounce, and dress the ground with slug powder. Prepare the ground for Cauliflowers as for Cabbage. Sow Dwarf Erfurt, ¼ ounce, in the second week of April and the first week in June. Sow Mustard and Cress every ten days from the first week in July to first week in September, 1 pint each. For Lettuces, apply manure 2 inches thick. Sow seeds each fortnight from June until September. Select the variety "All the Year Round," and sow just a little at a time, transplanting the seedlings as soon as they can be handled. For Onions, apply 5 inches deep of manure and dress the ground with superphosphate before sowing. Sow the seeds as soon as possible, and thinly. Sow Bedfordshire Champion Parsley as soon as possible. Use slug powder. Radish, red or white Turnip-rooted, sow every week from June to September 1, half-pint. For Spinach, use 2 inches of manure and some superphosphate. Sow every fortnight from end of June to first week of August, 4 ounces Victoria or Viroflay. Sow Turnips, from June to August 1, every three weeks just a small sowing; use superphosphate. Choose Snowball and purchase 2 ounces. Scarlet Runners might succeed. These are more profitable than French Beans in so elevated a position. Sow seeds in the second week of May and pinch the shoots to keep the plants bushy; purchase half a pint of seed. Sulphate of ammonia is useful applied to green crops. When watering any crop, dissolve 1 ounce superphosphate in every four gallons of water, if this manure is required. This year you must depend largely on annuals for providing flowers. Give each plant plenty of space, none less than a foot. Sweet Peas might be dotted in single clumps along the side of the path, and would produce immense quantities of bloom. Purchase plants of Aster Comet, and sow early in May seeds of Quilled Asters. Sow early in April seeds of Centaurea Cyanus, Chrysanthemum coronarium, double lemon and white, C. Morning Star, C. segetum, Clarkia Salmon Queen, Eschscholtzia Mandarin, stock-flowered Larkspur (salmon, white, and blue), Malope grandiflora,

Giant Mignonette, and Salvia Horminum. In mid-April sow Sweet Peas. At the end of April or beginning of May Larkspur, Rocket (mixed), Nigella Miss Jekyll, Dwarf Nasturtiums, Shirley Poppy, Gypsophila rosea, and Ten-week Stocks. Give the ground for these annuals a dressing 2 inches thick of cow manure, and once the plants are well started a sprinkling of superphosphate may be hoed in. Gladiolus brenchleyensis may be planted very thickly in April, and Goff's hybrids at the same time. Galtonia candicans may be planted at 1 foot apart at the end of March and Lilium tigrinum splendens, 6 inches apart; plant Montbretias at 2 inches apart as soon as possible. All these appreciate superphosphate dissolved in water or used as a surface dressing. A few early-flowering Chrysanthemums, Polly, Maggie, Goacher's Crimson, White Masse, say six of each, will yield excellent flowers for cutting. For another year you must select and plant perennials. Regarding the labour required, it is impossible to give a satisfactory opinion; very much depends on the men, on their methods, and many other circumstances. *B.*

Obituary.

Jonathan Myers.—We regret to record the death of this gardener from heart failure following bronchitis. Deceased, who was 82 years of age, passed away on Tuesday, March 10, his remains being laid to rest on Saturday, March 14, in Watford Cemetery. He was for a period of 52 years in the service of the Rt. Hon. the Earl of Clarenden, at The Grove, Watford. Deceased commenced his gardening career in Dumfriesshire, about the year 1840, and, after serving at Taymouth Castle gardens, and elsewhere, came to The Grove, Watford, in July, 1856, where he saw service under four generations of the Clarendon family. The late Mr. Myers was a man of great energy: he possessed a thorough knowledge of gardening, and the gardens at The Grove are largely the result of his designs. He leaves two daughters and one son to mourn his loss. Eight of the old workmen at The Grove carried his remains to the grave, his funeral being attended by many friends. Lord Hyde had started to attend the funeral service, but was prevented from doing so through an accident when on his way to Euston.

Quintin Read.—This well-known horticulturist died on the 12th inst. and was buried at Teddington, near Tewkesbury, on Monday last. Many northern and midland gardeners will hear the news with regret. For a considerable time Mr. Read was head gardener at Pleasley Vale, near Mansfield, and later at Sir F. T. Mappin's residence, Sheffield, where he succeeded the late Mr. Woodcock. Subsequently, he became gardener to the late Mr. Craven, at Whilton Lodge, Daventry, and was next appointed assistant horticultural lecturer to Mr. James Udale, for the County of Worcestershire, in which post he remained with credit to himself until his retirement to Teddington a few years ago. Mr. Read was a good gardener, and at one time a frequent contributor to the horticultural Press. *C.*

Answers to Correspondents

Cattleyas with Pale-coloured Foliage: *A. B.* If you ventilate the house more freely, and damp the floors beneath the staging, as you suggest, it would probably improve the condition of the plants, and therefore the colour of the foliage. Be careful that the heat of the house at night is seven degrees or so less than in the day. Too high a night temperature would affect the plants in the manner you describe.

Chrysanthemum W. J. Crossley: *J. W.* Many thanks for the flowers you send of this richly-coloured late-flowering variety.

Chrysanthemums: *F. G.* There is no disease apparent on your plant.

Cinerarias Failing to Flower: *Matlock.* Blindness in these plants is to be attributed to some check received during their earlier stages of growth. If the plants are afforded too warm conditions while they are in a young state their energies are devoted to flowering, although the inflorescence may not be developed. Later in the season this effort of fructification is arrested, and the plant then develops its lateral shoots. The plant never afterwards recovers from the check given to it during its early stages, and the terminal flower shoot never develops.

Cypripedium Leaf: *W. G. D.* The leaf sent shows that the plant is affected with the Orchid disease known popularly as "spot." It is difficult to cure when it is so fixed as in this plant, whose leaves invariably become spotted when approaching maturity. You might try re-potting into fresh compost, in which a proportion of loam-fibre is added. Take away all the damaged leaves, and if possible remove the plant to another house, or give it a position nearer to the glass of the roof in the same house.

Destroying a Tree Trunk: *E. D.* As you do not mention the size of the "butts," we cannot specify the quantity of saltpetre you will require. Take 1 gallon of warm water and stir in sufficient saltpetre until the liquid will absorb no more. Make a hole in the top of the old trunk and pour in the saturated solution, and when this is absorbed, pour in more, and again until the whole of the stem is thoroughly saturated. Then, on a fine day, apply a match, when the whole will consume.

THE LATE JONATHAN MYERS.

Grafting Wax: *Wisbech.* There are several methods of making grafting wax, but wax prepared in the following manner is so easily made, and has proved so successful in application, that we recommend it in preference to others.—Boil 8 lb. of resin in an iron pot until melted, then add 3 lb. of Russian tallow, when this has likewise melted, add 3 lb. of red ochre, keep these materials well mixed and boil for one hour. When the whole has become thoroughly incorporated, add 1 lb. of Burgundy pitch; continue to keep the ingredients well mixed together, but exercise care when adding the pitch. It can best be done when boiling has ceased, otherwise it will easily boil up and over the sides of the pot, which is not only dangerous but wasteful. In order to keep the wax, the best plan is to grease a tub and pour it in; when cool it will become hard, and pieces may be broken off and warmed in the iron pot over a fire made close at hand, in which condition it should be applied to the grafts with a stiff brush. There is a liquid grafting wax made with resin, tallow, spirits of turpentine, and alcohol, but to the inexperienced the process is rather intricate and not always a success, as unless the right temperatures are properly gauged, the alcohol and spirit are liable to be lost through evaporation.

Loganberries: *Wisbech.* At the present time the best way to increase your Loganberries is to layer them. From a growth measuring several feet in length, three or four layers can be put down which will form roots quickly, and if severed from the parent plant when well rooted, will produce good fruiting growths for next year. The stock can also be increased by cuttings and prepared in a similar way as those taken from Currant bushes. These should be inserted in the ground next October.

Names of Plants: *J. H. W.* Arisæma ringens, occasionally met with in gardens under the name of A. præcox.—*W. McI.* Phillyræa decora.—*J. T. L.* 1, Saxifraga pseudo-sancta; 2, S. apiculata.—*A. M.* Crocosmia aurea.—*A. M.* 1, Pteris tremula; 2, Pteris cretica; 3, Adiantum capillus Veneris; 4, Selaginella umbrosa.—*T. I. R.* 1, Cochlioda sanguinea; 2, Odontoglossum blandum; 3, Dendrobium chlorops; 4, Dendrobium Pierardii; 5, Odontoglossum ramosissimum.—*C. B.* Centradenia inequalateralis (syn. C. rosea).—*J. M.* Cupressus Lawsoniana var. gracilis pendula.

Peach Buds Dropping: *W. C.* This injury is not the result of a disease, but is due to some cultural error that has caused a check to the tree. By many growers it is ascribed to keeping the roots too dry during the resting season, but it may also be caused by an excess of moisture at the roots, or by any other unsatisfactory condition at the root system.

Pear: *H. T.* We have no knowledge of the "chalk" Pear.

Roses: *C. Reader.* The Bordeaux mixture is an excellent fungicide if mixed and applied with care. We cannot find any fungi on the specimens of your Roses.

Seeds: *Constant Reader.* The seeds appear to be still alive. Allow them to remain a little longer, and they will probably germinate; failing this, remove them to a warmer house.

Strawberries Dying: *G. B.* We find no disease present in the leaves you send. The injury has been caused by some check to the plants. Have you applied an excessive quantity of some strong fertiliser?

Zonal Pelargoniums: *H. R. G.* All kinds of cuttings, especially those of Pelargoniums, are liable to fail in the way you describe. This blackening of the stem of Pelargonium is worse in some seasons, when it appears quite epidemically. It is caused by a fungus known as Botrytis cinerea. This fungus is capable of causing serious damage in cold and unfavourable seasons. Cavara, an Italian fungologist, has studied this disease on Pelargonium zonale, and has proved that it is always more prevalent in rather mild winters, when it will attack almost every plant in a cold or temperate house. The following treatment has proved successful:—When planting the cuttings, use soil that has not been used for any other purpose. Mix it with sand and put the compost into 5-inch pots. Make six holes with a pointed piece of wood about 3 inches deep, fill into each hole a little sand and insert the cuttings, pressing the soil firmly down. Apply a watering and place the cuttings in a well-ventilated house or frame, but taking care to prevent sudden changes of temperature. When the cuttings have rooted, keep the soil in the pots rather dry until the season is advanced, when they must be repotted, singly. The fungus, which lives on any kind of decaying vegetable matter, has been detected almost always in leaf-mould, and in soil used previously for pot plants. When the cuttings are once attacked with the fungus, nothing can be done to save them.

THE RIVIERA FLOWER SEASON.

MANY English visitors to the French Riviera fail to see it at its best because they hurry away early in April, just when both the country and the flowers are developing their fullest beauty. The winter visitors have, however, much to be thankful for, since even during the unusually cold season of last year many curious shrubs and flowers were in bloom, much of the vegetation being of a sub-tropical character.

It is true that they see the Narcissi and the Violets and Anemones at their best, and also the Almond blossom and the "Mimosa" trees (Acacia) in March, followed quickly by the Cherry, the Peach, and still pinker Apricot. At the beginning of last April the pink blossom of the Apricot and Peach trees in the Hyères district lent quite a purplish haze to the landscape, the plain for miles being resplendent in its garb of pink mist, the blossom so soon afterwards followed by the delicate green of the young foliage which burst forth after the long-wished-for rain.

The Anemones of March are a joy in themselves, for what could be more beautiful than the large scarlet or purple flowers of Anemone coronaria, while the pink or mauve stars and silvery buds of Anemone stellata are everywhere to be seen, the plant being more widely spread than our smaller Wood Anemone at home.

A sight of the acres of Violets in the neighbourhood of Hyères is well worth seeing in itself, and the scene is made picturesque by the bright costumes and dark features of the Piedmontese women and girls who gather the flowers.

In March the marshes between Hyères and the coast are white with the blossoms of Narcissus Tazetta. The tall, cream-coloured and fragrant flowers with yellow centre are so beautiful that it is surprising this species is not more often cultivated, especially as it is also very hardy. Bulbous plants are a feature in the spring flora of the Riviera, and they comprise three very handsome wild Tulips. Tuberous-rooted plants, such as Orchids and Irises, are also much in evidence. In the Department of Var can be found more kinds of Orchids than are seen in the whole of the British Isles, many of them being abundant and striking. April and May are the best months for Orchids on the Mediterranean; indeed, the majority of the flowers bloom in one or both of those months.

If we take a walk at the end of April among the fields and foot-hills close to the ancient town of Hyeres, with its castle-crowned hill which forms so conspicuous an object in the landscape, on leaving the road we find the banks are blue with Borage, which has been flowering fitfully all the winter in common with the curious little Arum Arisarum, a southern plant, so common and attractive with its snake-like colouring and curious hood. In the dried-up bed of a stream skirting the path the white, nodding blossoms of a rare Garlic, Allium triquetrum, with its dagger-shaped stem and leaves, are in danger of being exterminated by an entanglement of Periwinkles with pale blue flowers. This species is Vinca media, and is intermediate between the V. major and V. minor which grow in England, but among the hills of Var the larger Periwinkle produces flowers of a size and colour quite unknown even in English gardens.

The bright Star of Bethlehem, Ornithogalum umbellatum, is another English garden plant often seen on the borders of field and vineyards. Among the weeds of cultivation is the rare Spiked Fumitory and the exquisite Oxalis cernua with its large lemon-yellow-coloured flowers which only open in bright sunshine. This is a Cape plant, which has established itself throughout the Mediterranean shores, and it is believed that it was introduced into Europe by two monks at Malta a century ago, for they transplanted two pots of the plant into their garden, whence it spread to Corsica and the shores of France. The leaves resemble those of Clover, just as do the leaves of our own Wood Sorrel, and for this reason it may have been seeded down as a very poor substitute for Clover in some of the public gardens on the Riviera, such as the Jardins Denis at Hyères.

As one leaves the cultivated fields and approaches the Olive groves and Cork-Oak woods with their undergrowth of Cistus and Lavender, we are impressed with the size of the Tree Heath (Erica arborea), whose white flowers have been trying to come out for so many weeks during the cold, early spring. Sometimes this Heath grows 12 or 15 feet high, and I measured one woody stem eight inches in diameter. The root is used in large quantities for the manufacture of so-called briar pipes,* and the whole plant is also burnt for fuel.

Everywhere among the hills a very beautiful wild Pea (a variety of Lathyrus Clymenum) cannot fail to arrest the attention of the passer-by. The standard or outer petal is of a rich red-purple tint, and the inner wings are of a delicate violet, while the keel is greenish pink; in fact, it reminds one of the old-fashioned Sweet Pea both in colour and habit, and although the flowers are smaller, it is quite as lovely an object. A wild Asparagus, A. acutifolius, grows in similar places and also in sandy ground nearer the sea. The young shoots are much sought after, for their flavour is better than that of the cultivated kind, and the graceful branches look charming when arranged with flowers, and, being wiry, they last many weeks.

There are three kinds of Cistus, all common about the hills of Hyères. The large, pink-flowered C. albidus† and two white-blossomed species, one, C. salviifolius, with flowers nearly as large as those of the former species; the other the smaller-flowered C. monspeliensis, which is very aromatic, and it is stated that Napoleon delighted in its scent when an exile in Elba. The plant (which takes its name from the ancient town of Montpellier), forms bushes which are sometimes higher than a man. These, and some half-dozen more kinds of Cistus, are very characteristic plants of the Mediterranean region, growing freely in several countries of Europe and North Africa.

A remarkable parasite grows upon the roots of at least two species of Cistus, both in the South of France and in Morocco. It is called Cytinus Hypocistis, and is a curious object in May, when it appears above the ground at the roots of the Cistus. At first it looks like some coral-red fungus, but as it develops the colour changes to a delicate yellow tinged with red. It grows to a height of four or five inches and is monœcious, the pistillate organs being in one flower and the staminate in another. This interesting parasite gives its name to the family Cytinaceæ, of which there are only about 30 species in the two hemispheres. This one abounds on the hills above La Croix (Var) upon Cistus monspeliensis, and I have seen it upon C. laurifolius in the Eastern Pyrenees. The host plant does not appear to suffer much from its ravages, which can hardly be said of certain other parasitical plants, such as Cuscuta or Dodder.

The Department of Var in Provence has the richest flora of any in France, and many of its plants are extremely rare. Some of these, including several discovered on the beautiful Isles of Hyères (the Stœchades of the ancient Greeks), have not yet been found elsewhere. A book on the flora of this interesting Department is being prepared by two competent French botanists who live there. *H. Stuart Thompson.*

* The term "briar" is a corruption of the French "bruyere," meaning Heath.

† Albia was the Roman name for Hyeres.

NEW OR NOTEWORTHY PLANTS.

NEW CONIFERS FROM FORMOSA.

In the Tokyo *Botanical Magazine*, Vol. xix., pp. 43-60, I endeavoured to enumerate all the species of Conifer known to be found in Formosa up to that date. The specimens I then determined were very poor ones, and some of them were entirely wanting in their cones. I have enjoyed no opportunity of examining them with perfect material until the recent exploration of Mt. Morrison by Mr. T. Kwakami and other gentlemen. In connection with this I was so fortunate as to secure several specimens of cones, which I proceeded to re-examine with the utmost care. As a result, I have found that, although they are very like the Japanese species in a sterile branch, there is no little difference between the Formosan and Japanese in the form of the cone. I find, however, that I must correct some of my former statements. The following are new species which are very near the Japanese species:—

* PINUS MASTERSIANA.

This Pinus very much resembles P. Armandii Franch., but differs from it by its reflexed squamae and larger cones.

† PINUS MORRISONICOLA.

THIS Pinus has been erroneously identified with the Japanese P. parviflora S. et Z. owing to the great resemblance in its sterile branches. But in the shape of the cone and seed it should be regarded as a new species different from P. parviflora. The scale of the cone is usually reflexed, and especially so in the scale of the basal part. The wing of the seed is much larger than that of P. parviflora.

‡ TSUGA FORMOSANA.

This Tsuga very much resembles T. diversifolia by the shape of the cone and of the bract, but differs from it by the seed having a longer wing and by the glabrous branchlets. It also resembles T. Sieboldii in the shape of the cone and seed, but is distinctly distinguished by the shape of the bract and by the shorter leaves. This new plant is, I think, just intermediate between T. Sieboldii and T. diversifolia.

* PINUS MASTERSIANA (*Hayata*), SP. NOV.—Rami teretes fusci, novelli glabri, cicatricibus perularum et foliorum notati. Folia in fasciculo quinque, aceroso-filiformia, acuta, dorso plana, in sectione triangularia, margine et in carina remote serrulata, 10 cm. longa. Strobili erecti, ovato-cylindrici, obtusi, 14 cm. longi, 7 cm. lati. Bracteae minutissimae. Squamae numerosae, orbiculares v. subrhombeae, acutae, sursum reflexae, basi breviter cuneatae, lignescentes, longitudinaliter rugosae, fuscae, dispermae. Semina obovata 12 mm. longa, 9 mm. lata, apice leviter apiculata, exalata, compressiuscula. Testa ossea, crassa, fusca, glabra; albumen crassum, oleosum. Embryo cotyledonibus 5, verticillatis.

Hab. in Monte Morrison, leg. G. Nakahara, anno 1905.

† PINUS MORRISONICOLA (*Hayata*), SP. NOV.—Rami teretes, perularum rudimentis notati, novelli pubescentes. Geminae ovatae, perulatae, perulis acutis, membranaceis, margine fractis. Folia in fasciculo quinque, fasciculis approximatis, acerosa, rigidula, 6-8 cm. longa, arcuata sed non torta, apice acuta, dorso plana, facie acute carinata, in sectione triangularia, margine et carina remote serrulata. Strobili erecti, ovato-elliptici, obtusi, squamis circ. 40 compositi, 7 cm. longi, 3 cm. lati, squamis ellipticis, basi cuneatis, sursum rotundatis, leviter reflexis, 3 cm. longis, 1·5 cm. latis, coriaceo-crassis, sublignescentibus, concavis, badio-fuscis, dispermis, sed interdum abortu monospermis. Bracteae brevissimae. Semen ovatum apice obtusum, 10 mm. longum, 6 mm. latum, testa coriacea pallide feruginea glabra, ala membranacea, tenui, cultriformi, 2 cm. longa, 8 mm. lata.

Hab. Shohakulin, leg. C. Owatari, anno 1898.

‡ TSUGA FORMOSANA (*Hayata*), SP. NOV.—Ramuli novelli tennes glabri, pallide fuscentes. Geminae perulatae, perulis obtusis integris. Folia approximata, distincte petiolata, petiolis brevibus semiteretibus, parum incurvis, linearia, 16 mm.–8 mm. longa, 2 mm.–1·5 mm. lata, apice obtusa vel emarginata, integerrima, glabra, coriacea. Strobili ovati, 20-23 mm. longi, 13 mm. lati, squamis circ. 20, imbricatis, coriaceis, basi truncatis, sursum suborbicularibus, integris, 15 mm. longis, 10 mm. latis, substriatis, pallide fuscentibus, bracteis brevissimis, rhomboideis, apice brevissime 2-lobatis, irregulariter dentatis. Semina parva, obovata, 4 mm. longa, vel longiora, ala membranacea tenui cultriformi, pallide feruginea, 7 mm. longa.

Hab. in Monte Morrison, leg. S. Nagasawa, anno 1905.

* JUNIPERUS MORRISONICOLA.

This species is erroneously identified with J chinensis. The habit of this new plant is very like J. chinensis, but is easily distinguished by its solitary ovule on a short branchlet, and by the shape of its cone. The leaves have a large single resin canal near the phloem. So far, the plant does not seem to have dimorphic leaves, all the specimens we have at present possessing but one kind of leaf.

† CUNNINGHAMIA KONISHII.

This interesting Cunninghamia was first collected by Mr. N. Konishi in Mt. Randai in the Island of Formosa, and was sent to me by Mr. T. Kawakami for investigation. He informed me that the habit of this new plant is an intermediate between those of Cunninghamia sinensis and Taiwania. On examining the specimen carefully I find that the cone of the plant has a secondary squama, and, therefore, this should be referred to Cunninghamia. The leaf of this plant has stomata on both surfaces, while the leaf of C. sinensis has no stoma on the upper surface, or at most but very few. This character of the leaf forms a kind of bridge over the gap which separates C. sinensis from C. Taiwania. This new Cunninghamia differs essentially from C. sinensis in the arrangement and shape of the leaves, in the smaller cone and its squamae which are depresso-globose. The timber is like other Conifers, the bark is reddish-brown, and in all respects closely resembles that of Chamaecyparis; but it has an odour peculiar to itself. The leaf of C. Konishii is more persistent than that of C. sinensis; the former lasts for eight years, the latter only lasting five years.

FIG. 81.—DENDROBIUM CRINIFERUM: COLOUR OF FLOWERS CREAMY-WHITE.

* JUNIPERUS MORRISONICOLA (*Hayata*), SP. NOV.—Rami teretes; ramuli novelli virides trigoni. Folia omnia lanceolata, apice acerosa, patentiuscula, 3-4 mm. longa, 1 mm. lata, supra concava, glaucescentia, subtus parum carinata. Flores masculi terminales in ramulis brevissimis, ovoidei, 4 mm. longi, 2 mm. lati, staminibus 8, squamis peltatis, suborbicularibus, 1·5 mm. in diametro, antherae loculis 3. Flores foeminei in ramulis brevissimis terminales, basi foliis squamiformibus bracteisque 6-9 oppositis suffulti, squamis intimis 3, ovatis acutis verticillatis patentibus. Ovulum solitarium terminale a squamis intimis 3 circumdatum, oblongum, apice attenuatum. Galbulus globosus 6 mm. diam. vel paues longior, in apice vestigiis squamarum intimarum suffultus, siccus nigricans glaber.

Hab. in Monte Morrison, leg. S. Nagasawa, anno 1905.

† CUNNINGHAMIA KONISHII (*Hayata*), SP. NOV.—Arbor ramis omnibus teretibus, glabris, foliorum spiraliter confertorum cicatricibus notatis, gemmis floriferis nudis, depresso-globosis, bracteis depresso-ovatis, brevissime aristato-acutis. Folia ramorum veterorum spiraliter conferta, adnato-decurrentia, anguste lineari-falcata, incurvo-erecta, acuta, dorso leviter carinata, ramulorum juvenum ascendento-patentia, longiora, anguste lineari-lanceolata, 15 mm. longa, 2·5 mm. lata, ad basin oblique torta, apice obtusiuscula, margine sub lente serrulata, rigida, coriacea, utrinque pagina glaucescentia, stomatibus multiseriatis instructa, octovum in annum virentia demum exarida sensim soluta. Strobili maturi ovato-globosi, 20 mm. longi, 15 mm. lati; squamae rotundatae, mucronatae, basi distincte unguiculatae, ungue brevi, lamina dilatata, cordata, late depresso-ovata, margine integra, lignescentes, sursum coriaceae, et marginem versus subundulatae, dorso apice leviter carinatae, glabrae; bracteae obsoletae, squamulae 3 in basi laminae squamae, distinctae, fimbriatae crenulatae. Semina 3 ad squamularum basin affixa, reversa, libera, ovato-elliptica, testa coriacea, duriuscula, ala angusta cincta; embryo ignotus.

Hab. in Monte Randaisan, Nanto, ad 7,000 ped. alt., leg. N. Konishi, anno 1907.

The habit of this new plant is very like J. chinensis, but is easily distinguished by its solitary ovule on a short branchlet, and by the shape of its cone. The leaves have a large single resin canal near the phloem. So far, the plant does not seem to have dimorphic leaves, all the specimens we have at present possessing but one kind of leaf.

† CUNNINGHAMIA KONISHII.

This interesting Cunninghamia was first collected by Mr. N. Konishi in Mt. Randai in the Island of Formosa, and was sent to me by Mr. T. Kawakami for investigation. He informed me that the habit of this new plant is an intermediate between those of Cunninghamia sinensis and Taiwania. On examining the specimen carefully I find that the cone of the plant has a secondary squama, and, therefore, this should be referred to Cunninghamia. The leaf of this plant has stomata on both surfaces, while the leaf of C. sinensis has no stoma on the upper surface, or at most but very few. This character of the leaf forms a kind of bridge over the gap which separates C. sinensis from C. Taiwania. This new Cunninghamia differs essentially from C. sinensis in the arrangement and shape of the leaves, in the smaller cone and its squamae which are depresso-globose. The timber is like other Conifers, the bark is reddish-brown, and in all respects closely resembles that of Chamaecyparis; but it has an odour peculiar to itself. The leaf of C. Konishii is more persistent than that of C. sinensis; the former lasts for eight years, the latter only lasting five years.

* CHAMAECYPARIS OBTUSA.

This Formosan Chamaecyparis is in all respects the same as the Japanese C. obtusa, but the cone is always much smaller than the Japanese one, and the seed is also smaller. Native botanists in the Island suggest to me to separate it from the Japanese species as a new variety. For the present I think, however, it would be better to regard it as a form of the typical one.

† KETELEERIA FORMOSANA.

This Keteleeria somewhat resembles K. Davidiana, but differs from it by its spathulate bract which is contracted a little above the middle portion. The cone is shorter and the wing of the seed is narrower. The leaf is acute or obtuse; but not truncate or emarginate as is the case with K. Davidiana. *B. Hayata, Japan.*

DENDROBIUM ACUMINATUM.
